"Electrical Engineering"

EVEN before you opened this issue of the monthly publication of the Institute you noticed a change. As you proceed through the pages you may sense more departures from the "Journal" of the last few years.

ALL this is part of an evolutionary scheme to enlarge the value of the Institute to every member regardless of age, location, responsibility, interest in the field of electrical engineering or in its professional significance. To bring the engineer to the Institute obviously is too costly in time and money; therefore, every effort is being made to bring the Institute to its members. Toward this end some years ago Sections were instituted and more recently District meetings were promoted to decentralize activities and render the national atmosphere frequently accessible to members everywhere. Now, as a next step, the monthly publication revises its format, and essays to interpret the latest technical developments and other matters of professional interest more in accord with the broad requirements of the whole membership.

IF these changes arouse in you a happy appreciation you surely will want to impart it to some hesitating applicant. Or, you could help the editor by telling him. In fact, why not tell him anyhow? This is your Journal and you have that privilege and duty.

President.

THIS, the first issue of ELECTRICAL ENGINEERING, marks another important step in the development of the American Institute of Electrical Engineers. Under this new and more appropriate title, the successor of the Journal of the A. I. E. E. will be published monthly as the official organ of the Institute, but with a much broader scope.

THE survey made during the past two years by the Publication Committee, under the able chairmanship of Mr. W. S. Gorsuch, clearly indicated a very general demand that the Institute continue to publish a high-grade electrical engineering periodical including, however, not only engineering and scientific papers and discussions presented at the various Institute meetings, but also much additional matter reflecting current progress in the art of electrical engineering.

ORIGINAL papers on theoretical or experimental investigations, important inventions, discoveries and developments in the fields of electrical engineering and the related sciences, will continue to constitute the major portion of the contents. The high standard that always has been maintained in the Institute's publications will be continued. Based upon the constructive work of the past, the broadened scope of the publication is a logical step in the evolution of the Institute, the purpose being to supply information that will enable the individual engineer to keep more fully informed of recent developments in the theory and practise of all branches of electrical engineering.

ELECTRICAL ENGINEERING will reflect the steadily increasing part that the applications of electricity are taking in our modern civilization. More attention will be given to the effects of engineering upon human relationships; in particular, the influence of electrical engineering in the fields of sociology, economics, and other social sciences.

THE ability of the leaders in the engineering profession, for effective collective effort, has been developed to a large extent by their activities in the Institute and in similar organizations. ELECTRICAL ENGINEERING is one of the instruments established by the Institute for the exchange of ideas, and it affords the individual engineer opportunity to contribute items of interest and value from his experience for publication in exchange for the ideas which he receives from other contributors.

THEREFORE, the Publication Committee and the editorial staff will be glad to consider contributions similar in scope to those published in this issue, in which a beginning has been made in the direction indicated. It is expected that the future issues will constitute, even more fully than the monthly "Journal" has in the past, an authoritative history of developments in the electrical engineering art and the related sciences, which together constitute the basis for evolution in the electrical industry.

F. L. Hutchinson

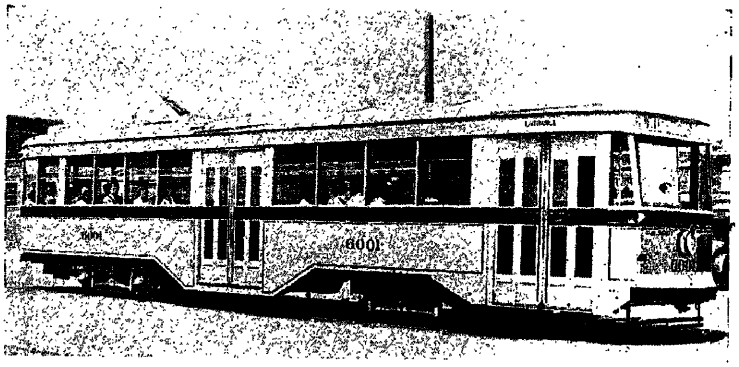
National Secretary.

Automobiles vs. Railways for Urban Transportation

Electric power in urban transportation presents an opportunity and a challenge to the electrical engineer that is emphasized more strongly as street congestion grows worse in all centers of population. Tremendous public expenditures are being made for street improvement, but will that afford economical transportation?

By Charles Gordon

Managing Director,
American Electric Railway Association



A 1930 model street car. Designed for comfort and high speed, it is a most efficient user of street space

FUNDAMENTAL to all industrial progress lies progress in transportation. Only as man has succeeded in overcoming the limitations of distance and time has he moved forward in mastering his environment. When man learned how to substitute energy derived from wood and coal for that of beasts and of his own body, the first extended commercial applications of the new power were made to transportation. Since then, the development of each new form of power has resulted largely from the dominating importance of the need for transportation improvement. It is quite natural, therefore, that the fiercest battles for achievement and for survival of the fittest among the vanguard of mechanical, electrical and automotive engineers are still being waged in the field of transportation.

Man first applied the magic of steam to make the railroad and the steamship. With them he took his first great step in the mastery of distance and time. Improved transportation permitted rapid growth of industrial and commercial centers which were required when steam-driven machinery in turn replaced handcraft. In consequence of these two developments, civilization experienced an industrial revolution.

Steam power has enhanced the economic importance of cities. Increasing numbers of people were drawn by economic forces to rapidly growing industrial and commercial centers. Therein was born a new need—the need for improved local transportation within these urban areas. For a time animal power was sufficient for the purpose, but as population and the areas of cities grew there was need for something more efficient than animal power; and without the smoke and other limitations of steam. That need stimulated the development of electric motive power and its first major application. Local transportation in cities offered early electrical men a most important commercial opportunity; it stimulated the development of generating, motor, and control equipment. Subsequently, as had occurred with steam, transportation shared with other uses its position as the major field for application of the new power.

It seems particularly significant to electrical engineers today, as an indication of the rate at which we are moving, that the history of electric power is encompassed within the lifetimes of two men whose names stand out in its early development. Sprague, who built what is counted the first commercially successful electric railway line, and Edison, who after conducting early experiments in lighting and transportation concentrated upon applying electricity to light the world, have both been permitted by kind Providence to live to see the marvelous achievements of their early struggles.

In the transportation field, for people who were content to travel collectively, steam and electricity reigned supreme. But the horse has survived and has continued for many years to serve those who required individual transportation or desire exclusiveness. The industrial age opened as a utilitarian age. Transportation men concentrated upon utility and efficiency, when the horseless carriage first appeared upon city streets they gave it barely passing attention. They failed to recognize its significance as marking the introduction of a new form of power—the internal combustion engine—applied to individual transportation. But within three decades, the automotive vehicle has so stimulated the desire for individual convenience, speed, and luxury in travel that it congests the streets of our cities and spreads out over the land on a gigantic system of highways built by the public to make its use possible.

An address delivered at the A. I. E. E. Southern District Meeting, Louisville, Ky., Nov. 19, 1930, under the title "Electric Power in Urban Transportation."

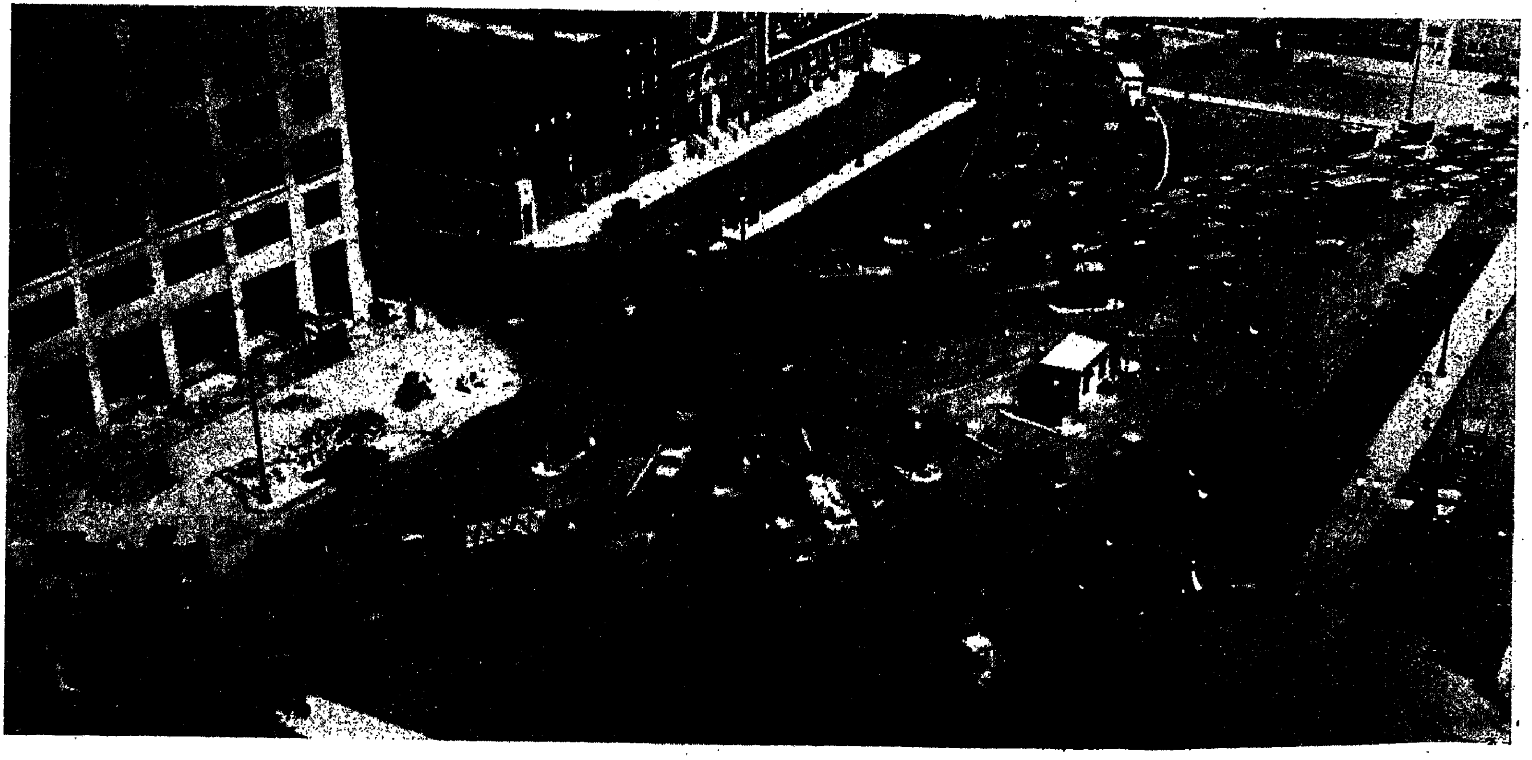
Again, the introduction of a new form of power made for new standards of transportation. Again, far-reaching social and economic changes result. Starting with the individual vehicle, the automotive engineer has cut the ties that bound man to earth and now carries him through the air. And while he pushes rapidly forward these achievements he also challenges the mechanical and electrical engineer in a field of collective travel. He has plunged into the transportation power battle both within and between cities, and contests at many points the reign of steam and electric power, on land and on sea.

So spectacular and rapid has been the progress made by automotive power that laymen and many engineers as well are inclined to write off electric transportation in cities along with the horse-car. And although they do not go quite so far as to relegate the railroad to the limbo of the stage coach, there is a strong tendency to assume that the internal combustion engine on the highway will rapidly decrease the field of usefulness of the steam engine on rails. In the early stages of railroad electrification there was a similar tendency in the minds of enthusiasts to consign the steam locomotive to the scrap heap; nevertheless, locomotive designers met the advance of electric power and have given way to it only in high-density terminal areas and under the special conditions presented by steep mountain grades. With these exceptions the steam locomotive continues to dominate long haul transportation.

It seems particularly timely, therefore, that electrical engineers examine a little more closely the problem of transportation in urban areas where the great electrical industry had its origin barely fifty years ago; and where, in turn, predictions are freely made that electric power will be replaced by the internal combustion engine. In this examination we shall need to concern ourselves as much with economics as with engineering, for it is on the scale of economics that the achievement of the engineer must be weighed and finally judged.

Before proceeding, one additional thought seems worthy of mention here; just as the automotive engineer took to the air to make further conquests of space and time in transportation, so did the electrical engineer make new conquests through the air in the field of communications. In these respective fields each reigns supreme and each one records almost daily, achievements which whet our imaginations in an effort to foresee man's next step to master his environment. It is not surprising, therefore, that the eyes and the minds of electrical engineers, as well as of the public at large, have been diverted from the relatively unspectacular field of urban transportation which gave electric power its early impetus.

Though not so spectacular and therefore less in the public eye, transportation facilities within urban areas lie at the very heart of our modern economic system, for these are points of concentration for our vast industrial and commercial machinery. Without adequate and efficient elevators the modern skyscraper would be impossible. Without an adequate circulatory system, the whole urban area in which the skyscraper and the factory, the apartment building and the department store are merely units, would cease to function; for the economic existence of these areas is dependent upon the travel facilities by which people may move conveniently between home and office, factory and store. In large measure, the economic height of the skyscraper is



Typical scene at the New York entrance to the Holland Tunnel under the Hudson River. A single track of street cars operating with seated loads would more than double the passenger capacity determined on one hand by land values, and on the other, by problems involved in providing vertical transportation. So also physical arrangement of cities as a whole, and the economic location and character of property development, are determined by land values and the facilities for horizontal transportation.

In every large city the demand for street space far exceeds the supply; in congested areas it is obviously impossible for all who would do so to move by individual vehicle. How then shall the need be met? Will it be by the construction of two, three, four or even more, levels of streets as some suggest? And if so, will these be for gasoline-propelled vehicles operating on pavements, or for electrically-propelled vehicles operating on rails?

There is little question as to the public's preference at the present time. While the electrical engineer has been concentrating upon utility and efficiency with little regard for mental and esthetic values, the automotive engineer has been directing his attention to speed, attractiveness, and even luxury in the design vehicles. The result was natural and inevitable; it verified an ages-old principle that the price which mankind is willing to pay to achieve a desire is measured by the intensity of the desire and his ability to make whatever sacrifice is necessary to achieve it. The automotive engineer sensed the importance of the desire for speed, comfort and luxury in travel, and concentrated upon meeting it. As a result the public likes and wants the automobile and will not be deterred by cost alone from providing facilities for its use.

Efficient local transportation is vital to the modern economic system. This loading terminal expedites traffic at a Detroit industrial plant

The prediction then that we shall build our cities of the future for automotive travel regardless of cost is sound in so far as it assumes that cost is secondary to popular desire. But in the light of facts it assumes that there is no limit to the price which the public is willing or able to pay to ride by automobile. It is not so much the cost to the individual to which attention should be directed—high as that may be—but the relative costs to the community, of travel by electrically propelled transit facilities and individual automobiles.

By considering the relative passenger capacity of roadways for individual vehicles as compared with the capacity of collective transportation facilities the magnitude of this problem may be grasped readily. Under extraordinary conditions, the maximum practicable capacity of a single lane of motor vehicles is approximately 1,800 vehicles per hour; this on the assumption of uninterrupted flow of passenger automobiles only, free from interference by cross traffic. For calculating traffic capacity of a street *free of all crossing interference*, the figure is high rather than low, and would represent a condition of congestion which would be neither convenient nor satisfactory to the operators of vehicles. For example, the maximum recorded traffic flow through the Holland Tunnel under the Hudson River between Jersey City and New York City occurring on May 30, 1930 was 1,253 vehicles per single lane. The ultimate capacity of the tunnel in two lanes is computed as 1,270 automobiles per lane per hour. For calculating highway capacities, let us use the figure of 1,500 vehicles per lane per hour *for a highway with no grade crossings*, which would represent the practical maximum at satisfactory speeds. Likewise, careful analysis of traffic checks taken under a wide variety of conditions indicates that approximately 900 vehicles per single lane per hour is a fair average for calculating the maximum practicable capacity of a single lane on a major arterial street or highway *subject to normal interruption of cross traffic.*

The above capacities apply only to a single lane; but roadways are not ordinarily single lanes, but consist of several lanes on which traffic weaves from lane to lane, reducing the capacity per lane as the width of the street increases. Though the exact effect of this factor of weaving upon multiple-lane highway capacity cannot be accurately measured, it can be fairly approximated and the figures below give the results to be expected under average conditions:

RELATIVE CAPACITY OF MULTI-LANE STREETS IN COMPARISON WITH SINGLE-LANE

Number of lanes in one direction	Efficiency per lane in per cent of single lane
1	100
2	89
3	79
4	70
5	62

The capacity of roadways of various widths is, therefore, readily determinable, calculation being possible under three conditions: First, express movement on a roadway with no grade crossings and no stopping; second, on a roadway such as a city boulevard subject to grade-crossing interference, but with parking prohibited; and third, a roadway with normal grade-crossing interference and with the further reduction

MAXIMUM PRACTICAL CAPACITY PER HOUR OF ROADWAYS UNDER TYPICAL CONDITIONS

	No Grade Crossings—No Stopping Permitted		City Boulevard with Grade Crossings—Parking Prohibited		City Street with Grade Crossings—Parking Permitted	
Roadway Width in one Direction	Number of Moving Lanes	Vehicles per Hour	Number of Moving Lanes	Vehicles per Hour	Number of Moving Lanes	Vehicles per Hour
20 ft.	2	2,650 (a)	2	1,200	1	750
30 ft.	3	3,550	3	1,800	2	1,450
40 ft.	4	4,200	4	2,200	3	2,000

(a) New Jersey State Highway Department estimates 2,400 cars per hour under similar conditions on the elevated express highway of Route No. 25.

in capacity from stopping and parking along the curb. These capacities are shown above.

In the last two columns of the foregoing tabulation parking necessarily eliminates completely the use of one lane; it also, due to the interference of vehicles moving to and from the curb, reduces the capacity of the lane nearest the parked lane. Under the conditions of capacity volume and one-hour parking regulations, it is safe to estimate that cars moving to and from the curb will reduce by at least 20 per cent the normal capacity of the lane next adjacent.

We are now in position to measure the *passenger* capacity of these typical roadways; observations made in a number of cities indicate that use of automobiles in city travel result in an average loading per vehicle of approximately 1.7 passengers. Consequently, in calculating the travel capacity of roadways in cities for individual vehicles it is safe to assume that the loading per vehicle will vary little from that indicated by these observations which represent averages over a considerable period in many locations.

For purposes of comparison, the capacities of electrically-propelled travel facilities in cities are readily determinable. A single track on an ordinary major city street—assuming conventional street cars, approximately 48 ft. long seating 60 passengers—has a maximum capacity of about 180 cars per hour. Through congested areas in some cities a number greater than this is actually being moved over a single track, but to insure satisfactory speed a maximum capacity of 150 cars per hour will be assumed. Thus, a single track on the surface of a conventional street will move 9,000 *seated passengers per hour*—considerably more than the number of people traveling in automobiles on a *grade-separated, elevated highway* with four express lanes in one direction. Putting this in another way, the passenger capacity of a single track of conventional street cars, carrying only a *seated* load and running on a main business street subject to cross traffic interference, is more than twice the observed maximum through the present Holland Tunnel under the Hudson.

Furthermore, if two such tracks are located in the center of an ordinary 60-ft. roadway with parking prohibited, approximately 1,000 automobiles per hour may move through this street in each direction, thus making the capacity of such an ordinary 60-ft. city street, subject to cross traffic interference and with street cars carrying only a seated load, two and one-half times the passenger capacity of the Holland Tunnel. If we remove the street cars and turn over such a 60-ft. roadway exclusively to automobiles, continuing to exclude parking, it will require *in addition to the old street,* two and one-half new boulevards of the same width to move the same number of people.

In these comparisons, bear in mind that street cars are assumed to carry *seated loads only,* and highway lanes are assumed to carry the maximum number of automobiles that can move at approximately satisfactory speed.

The future use of electrically-propelled public transportation facilities in cities will be determined by the extent to which they can approximate automobile standards of comfort while retaining the substantial advantage of great economy in space requirements. It has therefore been assumed that in comparing the space requirements of an adequately developed public transportation system with a highway system for automobiles every passenger is an ideal standard of comfort.

When the growth of a city and consequent density of travel requires the construction of additional facilities above or below the present street surface, the community has the alternative of designing these facilities for collective travel in electrically-propelled vehicles on rails, or for individual travel in automobiles. It is important therefore to examine the relative carrying capacity of these two alternative forms of construction: Here, the community is called upon to provide new facilities for its circulatory system; under given conditions of travel density the number of new grade-separated arteries required, whether overhead or underground, will be determined by their passenger carrying capacity, established in turn by the decision as to whether they are to be equipped with roadways for automotive vehicles or with rails for electrically-propelled cars or trains.

One four-track subway, of 56-ft. excavated width and carrying two express and two local tracks like the New York subways has an ultimate capacity of 35 ten-car express trains per hour on a single express track and requires 30 six-car local trains on the adjoining track for intermediate station transfer travel. Assuming only a seated load per express train and corresponding conditions in local trains, such a four-track system will readily move approximately 47,000 people per hour in each direction. To permit these people to move by automobile, assuming that they could afford to do so, the community would have to provide approximately 10 elevated or underground highways of corresponding width. Here again, the capacity of electric trains is calculated on *a seated basis only.* It would require at least 20 tunnels or elevated highways of equal width to carry in automobiles the people actually transported at present standards of loading on one four-track line of subway in New York.

To solve the growing problem of traffic congestion in cities it seems hardly conceivable that the enormous economic advantage of collective transportation by electric power will not be utilized to a much greater degree in the future than at present. It is true that a much higher standard of convenience and comfort for collective transit facilities is necessary, but compared with community cost of rebuilding our cities for automobile travel, the economic advantage lies all with electric power in urban areas of high travel density.

May it be suggested therefore that the electrical engineer has a great opportunity and a great responsibility in the field of urban transportation—the birthplace of electric power. Not alone as engineers but as citizens of the community is it incumbent upon those in position to understand the intricacies of local transportation to aid in the adoption of sound civic policies. The future trend of development will be influenced by psychological and political factors as well as by economic and engineering considerations. The battle of power in transportation will continue to be waged not alone in the drafting room and laboratory, but in the arena of daily life where the public is the judge and where economic and engineering data may be outweighed by visionary schemes which appeal to the popular imagination.

◆ ◆ ◆

Industry Vs. Technical Education

Industry wants better men; educators want better support. Frank statements by leaders of both contingents are illuminating to young engineers and pave the way for co-ordinated attack upon a common problem.

INDUSTRY WANTS the technical schools to turn out men more soundly trained in the fundamentals of scientific and sociologic knowledge. Against this, the technical schools look to industry for more definite support and greater cooperation in the matter of certain specific educational problems.

Such are the impressions gained from expressions of nationally prominent leaders in industry and education as they presented their views and substantiations at a "Conference on the Relation Between the Industries and the Technical Schools," held at Lehigh University, Bethlehem, Pa., October 16, 1930, in connection with the dedication of the James Ward Packard Memorial Laboratory of Electrical and Mechanical Engineering. Excerpts from several of the speakers appear in the following paragraphs:

F. A. Merrick, president of the Westinghouse Company, undoubtedly sounded the keynote from the industrialist's standpoint when he said ". . . What the industry wants is men who can and will do some one thing better than it has ever been done before . . . who can add something to the sum of human experience, whether that experience has to do with design or manufacture, or research, or selling, or administration . . . and the technical man who is properly qualified and trained and willing to work has no limit to his possibilities in the (industrial) field.

"Industry expects a group of men so selected and so trained in fundamentals and in analysis, and in the application of such analysis to practical problems, that they can develop into the doers of everything needful for the solving of each problem in the whole range of requirements. It does not, however, expect men from the schools . . . to solve every problem concerned . . . much less all of them . . .

"The reasonable expectation of industry is satisfied if, for instance, Graduate A emerges with the capability of developing into the best there is in such-and-such a division of the field, while Graduate B is qualified and fitted for similar development in another perhaps equally important field; and Graduate C for still another field, and so on. The sum of A + B + C is what the educator is expected to furnish. . . . So the indicated procedures should aim to provide first of all a basic training that later would be usefully employed no matter in what class of organization the graduate might find himself . . . .

"The most frequently heard criticism of the technical man is that he is lacking in human understanding and in acquaintance with the world of affairs; and along with these deficiencies very often he is lacking in the exercise of adequate expression in speech or writing, especially on the subjects involving anything outside of purely technical subjects . . . .

"In confessing that there is considerable ground for this judgment it must be remembered that the ordinarily required preparation for a technical course makes great demands on the young man's time and energy. The same thing may be said of his pursuit of the subsequent technical career. All of this makes it doubly important that an early foundation in the so-called humanities studies should have due consideration in making selection among those applying for admission to the technical schools . . . . Post graduate work might in some cases—especially in research—be employed profitably in the schools, though as a broad proposition the real specialization comes only in the actual contact with the school of experience in the industry itself."

Alfred R. Glancy, president of the Oakland Motor Car Company, in echoing Mr. Merrick said in part: ". . . Industry is asking for men thoroughly trained in the fundamentals and with personality, . . . generous in tolerances, and humble; not with the humbleness of acquiescence, but the greater humbleness that is willing to take the suggestions of a better man and use them. . . . They should have disciplined spirits."

Mr. Glancy stated frankly that "engineering departments of many technical industries are carrying heavy quotas of foreign-born and foreign-trained men because these men with their practical foundations of scientific training are capable of great development. Also these . . . men do a more thorough job. They are happy with gradual advancement, which in turn makes for thoroughness of execution. Frequently, after two or three months on the drafting board or a similar time in the shop, our American graduates are discouraged because the glamorous executive positions about which they have heard so much are not immediately open to them."

In reporting upon a personal survey among motor-car manufacturing executives, Mr. Glancy stressed the undesirability of narrow specialization upon the parts of technical students, "for instance, in gas engine design." With equal emphasis, physics, chemistry, mathematics, English, political economy, economics and a "seasoning" of the purely cultural subjects were unqualifiedly recommended.

Matthew S. Sloan, president of the New York Edison Company, spoke with characteristic frankness representing the utilities view: ". . . . We seek men who have attained good academic standing in their classes, but not necessarily the highest. We expect them to know their books and tables, but we expect them to know a good deal more; to know, for example, that books and classroom work are simply a foundation and that some of what they have been taught is already out of date or wrong. We expect them to know how to reason—how to think. We expect them to have curious minds, inquiring minds, eager to acquire information, active to associate it with other information, able to digest it and put it to use. We want them to have initiative and character. We want them to have intellectual and moral as well as physical courage. We want them to have a personality which will enable them to deal successfully with a trench digger or the presidents of the companies. We want them, having information and ideas, to be able to present them clearly and persuasively, orally or in writing.

"We want these men to have a technical education.—Yes, but a technical education which will help them in learning our business, and not one which will send them to us with a lot of theory which they will have to unlearn because it is behind the standards and practises of our business. I am speaking frankly. The practises of our business must always be in advance of what is taught in the classroom because it is impossible for the schools to keep abreast of practises in our industry where improvements are being worked out from day to day. We want technical graduates who have been taught how to learn, how to adapt themselves in the school of trial and work."

Bancroft Gherardi, vice-president and chief engineer of the American Telephone and Telegraph Company, and past-president of the Institute, also emphasized the importance of fundamentals: ". . . What we want are men who can recognize the problems with which they are confronted, study the problems, determine the appropriate action, and then take such action in the right way. For men in the administrative and general engineering departments, these seem to me to be the essential requirements . . . Train the student to recognize the necessity of getting his facts; teach him the best methods of getting them, and train him to interpret engineering data and reason therefrom.

"One of my strongest convictions is that unusual effort may well be made to reach every engineering student to speak and to write a report or letter in clear, convincing English, setting forth the facts, arguments, and conclusions pertaining to the question before him. It is of the greatest importance to an engineer that he shall be able to state in correct and logical form the problem before him, and to enforce his conclusions with arguments which shall be convincing. Such training as this is not merely one in literature, composition, or rhetoric. To present such a report, the problem must

James Ward Packard Memorial Laboratory of electrical and mechanical engineering, Lehigh University, Bethlehem, Penna., where educational-industrial conference was held in connection with dedication ceremonies.

have been mastered and clear thinking must precede clear speaking or writing."

L. Warrington Baldwin, president of the Missouri Pacific Lines, likens the technical school itself unto a manufacturing establishment: ". . . The technical school today is essentially an industry. You may call it a foundry, melting and molding a material which we designate as a student mind into a crystallized and permanent thing we call a matured mind. You may call it a builder, shaping into a permanent structure of many parts the various things we call research and the application of the products thereof. You may call it the creation of an asset we call capital, a salable article or medium of exchange coined from the ore of natural and able mentality and offered for a circulating medium which, if the ore be good and the alloys strong, will not depreciate by usage . . . . .

"If the product of technical schools is to be a factor of increasing value to industry, it will have to insure in its operations the same progressiveness that characterizes industry. This is foremost in importance and cannot be overestimated . . .

"Great care must be used in outlining a course of study for young men looking toward the occupancy of executive positions. They should not be given the idea that a course of study alone will fit them for such positions any more than will a course in art insure that the student will become a great painter or a course in literature create a renowned author or historian . . .

"It should further be impressed upon the student that his diploma is not a magic wand which will open to him the door to success, but that after graduation and the securing of a 'job' and not a 'position' as a start, his progress is almost entirely dependent upon himself, except as it may be modified by fortune or misfortune."

EDUCATORS' POINTS OF VIEW

Paralleling the demands of the industrialists, the educators made some demands upon and suggestions to industry.

Arthur M. Greene, Dean of Engineering at Princeton University, commented upon the limited amount of time available to the technical school in which to educate its students saying, ". . . in this limited time only the fundamentals can be taught, and special details of a particular branch of industry should be given to its new employees by the industry itself, using that which the schools have done as a basis for this further training . . .

"Another thing which we should ask from industry is a constructive criticism of the work which we are doing as shown by our graduates . . . Could not industry in a fair, frank way inform us of any lack seen in our particular men? Of course, as engineers we should like both sides of the picture; and if our men appear to have a proper appreciation of these fundamentals and ability to grasp the new details which are presented, we should like to know of it so that we may carry on in this way which has produced these good results. Records and reports are to be used not only to eliminate faults but to maintain virtues . . .

Doctor Greene suggested that industry make more effort to carry on important researches in and with the cooperation of the laboratories of educational institutions so that students may benefit by contact with practical problems, industry may benefit by additional and independent points of view, and the school may benefit by having the use of special equipment installed by industry for its researches. Continuing he said, “At some of our technical schools cooperative research problems are being worked out by industry and the schools . . . The technical schools have the personnel, the equipment, and the space by which many problems of industry could be solved for those without research facilities; and for those with great facilities, these institutions are the natural places to which to turn for independent, original, or confirmatory work. The schools expect that industry will seriously consider this subject . . .

“The outstanding activity on a fairly large scale by industry, the summer conference for engineering professors by certain large manufacturing companies is one which the schools hope for from industry as a whole

Could not the smaller industrial plants offer summer employment to one or two men from the schools, even though a large conference is not possible? Each school has near it a number of industrial plants into which its teachers would fit.

“One of the requests which my own institution is making of industry is the summer employment of students, particularly for men who have completed the junior year. Many employers have granted our requests, and I now ask if this is not one which industry in general should expect from the schools. This would be for the purpose of giving the student a professional and commercial point of view to bring back to his college work, and at the same time to give the employer a chance to try out a possible employee for the next recruiting season.”

D. C. Jackson, head of the Electrical Engineering Department of the Massachusetts Institute of Technology, pointed out that: “. . . Engineering schools expect industry to recognize the duty of the schools as educational institutions to maintain independence in thought, in subjects and methods of research, and in opinions. In return, the faculties should recognize a duty to refrain from spreading inadequately founded opinions and from dogmatizing in controversial fields . . .

“Engineering schools expect industry to recognize the importance of independent operative scientific research as part of the life of the faculties and students, and to support it with contributions of money and counsel made to those schools which are adequately manned and equipped, to the end that additional knowledge may be disclosed, out of which industry may forge new applications; and also, to recognize the importance of such research as a pedagogical instrument in those schools which are manned and equipped to carry it on properly.

“Engineering schools expect large industrial establishments in their own interest, to pay more attention to the assimilation of recent graduates into the industrial work for which they are employed. With few exceptions the present practise is to fit these new employees into places requiring very limited needs, and to make no provision for such employees to gain (except by chance) an understanding of the accomplishments expected of them, thus leaving them ‘wallowing around’ for months without light or leadership . . . Engineering schools expect that the personnel problem of employing young men who are on the eve of completing formal study in the schools will be dealt with by the employing agents of the industries in a judicious and discriminating manner . . .

“That the public may come to realize the propriety of industry making contributions of generous size to selected engineering schools for the support of independent research in those schools, engineering schools expect that industry will aid in laying before the public a fair statement of the public interest in continued industrial development and invention, and the need

Main floor, electrical end, Packard Laboratory. Mechanical equipment in the distant half and lighter apparatus conveniently placed around spacious balcony; careful planning facilitates maximum student use of equipment provided by a far-sighted industrialist of maintaining independent research in the engineering schools, in order that a stream of results may be available as raw material out of which to mould further industrial development and invention."

An Important Suggestion

One of the most far-reaching suggestions of the conference was voiced by David E. Ross, president of the board of trustees of Purdue University. Mr. Ross urged that: "it is not unreasonable for our higher schools to expect industry to help in the searching out of fine-grade human raw material with which technical education must work . . . If industry builds widely for its own future, adequate provision will be made whereby the brilliant mind-constructing teachers in the universities will have reward and remuneration commensurate to those granted productive industry. Technical education would gain immensely if a certain large proportion of the men who have attained recognized superiority in industry were permitted to return to the university to contribute, as only they can contribute, to the training of the new leaders in our material civilization."

Australasia as Seen by an Engineer

South Pacific continent and its neighbor island present many features of interest; glimpses of a few are given here.

By Paul M. Lincoln

Director, School of Engineering
Cornell University
Fellow, A. I. E. E.

FROM HONGKONG to Brisbane, Australia, is a three-weeks' journey—an indication of the magnificent distances which separate Australia from the rest of the world. The latitude of Brisbane in the southern hemisphere corresponds closely to that of southern Florida in the northern hemisphere, and January temperatures are about what one might expect of southern Florida in midsummer. General dryness of the air, however, makes the high temperature quite bearable.

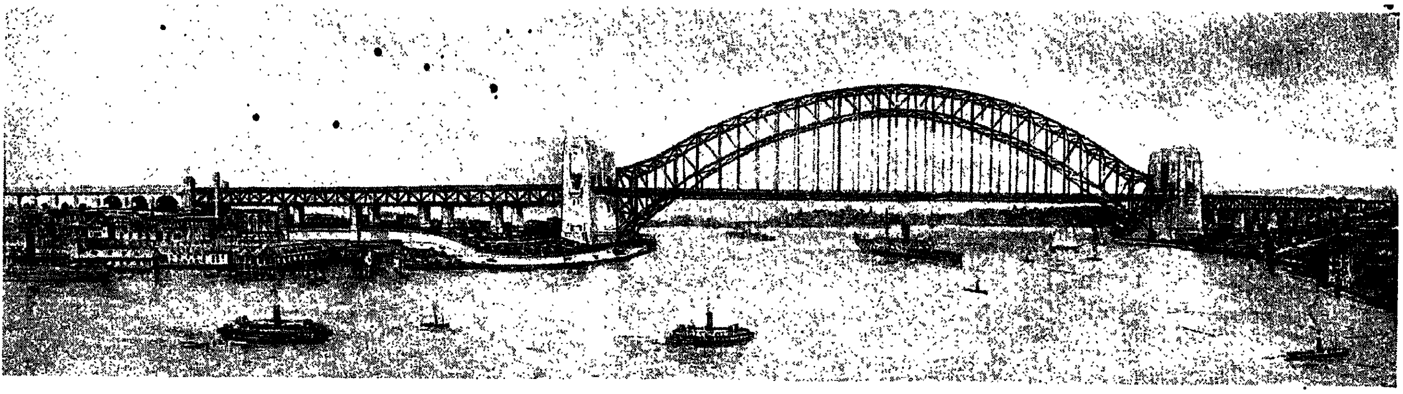
As a northerner travels overland from Brisbane to Sydney, one of the noticeable things about the Australian landscape is the total absence of both the flora and fauna of our northern hemisphere. Practically every recognized plant or animal is an importation from the North. As is well known, some of the transplanted animals and plants have become well-nigh insufferable pests in the southern hemisphere. The rabbit, which to us in the North is probably the best known of these, has multiplied so rapidly in Australia that it has become a distinct menace to the grains and other plant life of that continent.

The cactus is another imported pest: particularly in Queensland has the cactus spread rapidly and occupied lands that otherwise would be available for grazing or cultivation. Its spread has caused much apprehension in Australia and recently a cactus pest was introduced which it is hoped will hold the cactus in check. Still another pest is the blackberry, which is particularly troublesome in New Zealand. Large areas of that country have already been overrun by the blackberry and as yet no adequate means of checking its spread has been found.

Sydney itself, a busy, bustling city of approximately a million inhabitants, has one of the finest harbors in the word—the finest, if one is willing to accept the Sydney citizen's own appraisal. However, since it has been found necessary to throw a bridge across it to the north at a high cost this harbor might in one sense be viewed as a handicap. Rapid growth of the city has made more usable territory desirable and the bridge connecting Sydney to the North Shore is now under construction; its completion is expected some time during 1931.

Another thing about Sydney that is reminiscent of New York City is the torn-up condition of the streets incident to the installation of a subway system. As in many another city, growth has made necessary a better transportation system, and again subways have been selected as the best available means of supplementing existing systems.

In the State of Victoria the development of greatest interest to the electrical engineer is the use of the brown coal at Yallourn, a district about 100 mi. east of Melbourne. This coal bed lies under an overburden of earth only about 30 ft. thick, a condition which permits open-cut workings with resulting nominal mining costs. At the present scene of mining operations the thickness of the coal layer is about 180 ft., but in some parts of the field, borings to the depth of 1000 ft. have shown several superposed beds of this coal having a total thickness of 808 ft. It is estimated that there is available for mining by the open-cut method at least 20,000 million tons. In the area of one square mile set aside for the initial workings, the existence of 150



Sydney Harbor Bridge (Australia), under construction to relieve traffic congestion, reminds one of the famous Hell Gate Bridge in New York.

million tons has been proved, a supply sufficient to serve a 150,000-kw. power station for one hundred years.

The moisture content of this fuel is unusually high, varying from 50 to 65 per cent, and naturally results in a low heat content as compared with the usual black coals. With a 60 per cent moisture content, the calorific value is about 4700 B. t. u. per lb. In spite of the low heat value the small cost of mining makes this fuel an economical source of power. The great problem has been to find the proper methods of burning it under boilers. The little experience that was available was in connection with the development of the brown coals of Germany, and it is only natural that much of the mining machinery used at Yallourn was designed and manufactured in Germany.

The major market for Yallourn power is Melbourne, 100 mi. away. However, some fifty or more other municipalities and townships in the State of Victoria are deriving their electrical power from Yallourn and its associated power stations. Eventually the system undoubtedly will cover a large portion of the State of Victoria.

At the present time, a small amount of water power is being developed and fed into the general transmitting and distributing system, and further water-power developments are contemplated for the future.

By most of us here in the United States New Zealand is considered as being a close neighbor of Australia; hence it is rather surprising to find that the run from Sydney to Auckland is nearly 1500 mi., or four days' sail, equal to nearly half the distance from New York to London. New Zealand differs from Australia in its abundance of water. Snow capped mountains reaching a height of more than 12,000 feet abound, particularly in the South Island. This rough terrain together with the abundance of water gives the country a decided preëminence in the matter of water-power. More than 80 per cent of the electrical energy used in New Zealand is developed by hydraulic plants. Of course in New Zealand as well as in Australia generation and distribution of electricity is carried on as a government enterprise.

New Zealand is divided into some 50 or 60 districts in each of which a "power board" (in every case a creature of the government) has complete authority in the matter of the generation and distribution of electricity. The extent to which the country has been electrified is astonishing; it is stated that at the present time 75 per cent of all possible users of electricity in New Zealand are being served, and that there is hope to increase this figure within a few years to 90 per cent. This really is remarkable when one considers that there are only about one and one-half million people in New Zealand with an area of 105,000 sq. mi. In other words, the average density of population is less than that of the state of Nebraska. In these electrical "undertakings" there is no endeavor to make a profit. Rates for service are so fixed that only cost of service will be met, including of course a sinking fund that eventually will cover the original first cost. This policy explains why New Zealand is able to serve so large a proportion of its sparse population; the fat districts carry the lean.

New Zealand and Australia are almost entirely pastoral; wool, mutton, beef and dairy products constitute by far the greatest proportion of all exports. As might be expected of countries so young and sparsely settled, very little manufacturing is done.

A thing that one cannot but note in both New Zealand and Australia is the strong sense of loyalty to the mother country. Other things being equal, the Australasian will buy his requirements from England or at least from some other part of the British Empire. In spite of this pronounced British preference, however, the prevalence of American automobiles is noticeable. According to personal observation at least 90 per cent of the automobiles in Australia and New Zealand are of American manufacture. To queries as to why this should be, answer was given that the American automobile suited Australian road conditions while the British did not. The Australasian was very frank to say, however, that if he could get a British machine that was suitable and right in price, the trade would go to Britain.

Automatic Operator Improves Efficiency

Because the burdensome detail of maintaining accurately predetermined loading schedules is more than present-day minimized operating forces can handle, seldom are hydroelectric generating stations operated at maximum efficiency when under manual control; automatic control equipment subject to manual regulation solves the problem.

By S. Logan Kerr

Research Engineer,
I. P. Morris & De La Vergne, Inc.,
Philadelphia

GREATER EFFICIENCIES in hydroelectric plants must come from plant design and operation rather than from further refinements of design in the hydraulic equipment itself. The single important exception to this is to be found in the development of a new type of propeller turbine with automatically adjustable blades, the development and use of which is an important step toward bringing low-head plants to the relatively flat efficiency curve which hitherto has been found only in the medium- and high-head installations.

Operation studies of a number of plants show conclusively that the average operating efficiency rarely equals the maximum over-all efficiency of the station. In one of the newer large hydroelectric plants in the East, the over-all efficiency of the station was found from tests to be approximately 90 per cent, whereas detailed analyses showed that the maximum normally obtained in daily service was only about 80 per cent. The 10 per cent margin between these two figures was traced directly to inefficient loading of the plant and inefficient load distribution between the various units within the plant.

Other factors, such as the unnecessary lowering of the maximum operating head in the excessive drawing off of the small ponds and storage reservoirs, greatly impair over-all station efficiencies. Attention directed to these factors indicates a fruitful source of study for improvement in operating practise with recovery from losses to proportions hitherto unsuspected.

Hydroelectric stations of course must be operated with a definite understanding of the capacity of the station's available stream flow, the market for power, and the operating characteristics of the system to which its power is being supplied. For a plant in service, the general operating problems in so far as they are considered with respect to economy may be classified as follows:

1. Economic load distribution between units for any given station load and combination of generating units.
2. The economic output of the station corresponding to the points of maximum efficiency for the various combination of units.
3. The maintenance of the economic number of units or combination of units in service for any given load on the station.
4. The maintenance of maximum operating head and conservation of flow.
5. The control of pond levels with respect to flow when surplus water is available.
6. The maintenance of sufficient system reserve capacity to provide for system requirements, to be operated in parallel with the system and carried at a minimum cost. This may be divided into two types; reserve for immediate availability and reserve for delayed availability.
7. The maintenance of a fixed draft of water from storage reservoirs or through run-of-river plants, to supply the proper water balance on a given stream where more than one station is installed, in order to provide for plants farther down the river or to absorb the discharge from plants above the one under consideration.
8. Automatic frequency control to maintain constant frequency with the possible refinement of maintaining constant average frequency where electric timekeeping is a factor.
9. Automatic power-factor correction to improve line and distribution voltages and power factor within the limits of the machine capacities and by utilizing surplus machine from time to time as synchronous condensers.
10. The possibility of making use of flood water to increase the annual plant output.
11. The economy of spilling water over a fixed-crest dam under low-water conditions to secure full maximum operating head.
12. The possibility of increasing net plant output by decreasing the output of certain machines below the point of maximum individual efficiency.

The first five of these classifications deal principally with the hydraulic characteristics of the plant itself; Items 6 and 7 deal with the relation of the plant to system operation; and Nos. 8 and 9 may be classed as effecting the type of service rendered by the power company. The last three were suggested in a discussion presented by C. F. Merriam of the Pennsylvania Water & Power Company, Baltimore.

Most of these items have been given some attention by operating engineers but in most cases further attention could be given to advantage. Too much emphasis can not be laid upon the desirability of greater utilization of field-test results as a basis upon which to achieve better standards of operation and increased efficiency of utilization of the plant itself. Field tests can be made cheaply and simply in practically all plants by either the Allen or Gibson methods; and where these methods cannot be applied it usually is possible to employ current meters with a reasonable degree of accuracy provided sufficient care is used.

From "Automatic Operator for Economy Control," presented at the A. I. E. E. Middle Eastern District Meeting, Philadelphia, Oct. 13-15, 1930.

For purposes of determining the proper loading of the individual units, and the proper combination of units for maximum over-all efficiency for any given station output, accurate determination of unit-operating characteristics should be prepared along with schedules of economic load distribution between the units. In existing stations, a careful analysis of operating records taken from the daily log sheet will provide the bases for these determinations. For new plants, acceptance test data will serve; and where accurate test data are not available, it is possible that a combination of the manufacturer's test curves and the manufacturer's expected curves, combined with power-gage-opening tests on the actual installation, will provide sufficient information from which to prepare operating charts for units having similar characteristics.

For units with dissimilar characteristcs—which of course include units of different specific speeds and capacities, and occasionally units having the same capacities and speeds but built by different manufacturers—field efficiency tests are the only dependable source of information.

With the station and unit characteristics determined, an over-all schedule of operation may be prepared which will specify for each load on the station, the number of units required to carry the load, the proper combination of units, and the proper loading of each unit in order to maintain the best over-all efficieny. Based upon an estimated percentage of adherence to such a schedule, the question of load factor, load demand, and the rate of draw-down of the forebay, can be studied in their effects upon the maintenance of the maximum head. In cases where appreciable pondage or storage is available, a nice balance may be worked out between the permissible rate of draw-down during the demand hours and the building up of the head-water level at night. With low- and medium-head plants, particularly in a series development without head overlap between plants, it is of great importance in order to prevent loss in output and efficiency, to maintain the maximum possible operating head.

The factor of system reserve capacity also is one which should receive abundant attention and careful study to determine a reasonable margin of reserve to protect the system adequately against any shortage of power during sudden demand periods and at the same time to avoid excessive waste water arising from carrying too much reserve in parallel with the system. Because of the requirement of shutting down and starting up units at the proper time this phase of operation introduces still another burden upon the operating staff; also, because of the necessity for maintaining sufficient capacity in service to care for the normal operating emergencies which would cripple service if such reserve capacity were not immediately available, it introduces a serious responsibility upon the part of the system load dispatcher.

Studies of actual cost of carrying reserve capacity in any one plant, or with any combination of units can be made. On the same basis additional studies will indicate the desirability of operating units as synchronous condensers or merely as reserve capacity floating on the line. At most plants some saving can be realized by motoring the units from the line with the wheel gates tightly closed and the runner vented so that it operates in air rather than in water. The difference between the cost of maintaining the reserve by these two methods and that of having surplus units of light-load capacity represents a marked saving if the element of availability is assured.

It is self-evident of course that all of these factors have been given, and are being given, attention by operating engineers; the one element, however, which has hampered seriously the achievement of ideal economy in operation has been the necessity of depending entirely upon the human element. Further aggravating this same difficulty has been the tendency to reduce operating forces to a minimum, resulting in increased duties and responsibilities for the individual operators. Thus, the operator's attention has been forcibly directed to the prime requirement of maintaining continuous service, the question of economy necessarily becoming of secondary consideration.

The burden of maintaining accurate loading schedules, and of giving careful attention to each of the factors outlined at the beginning of this article, will pass beyond the realm of possibility for manual operation unless the present trend is reversed with a considerable increase in operating staffs and provision for rigid supervision. It is in this connection, because of the operating efficiencies that can be achieved with it, that automatic-control equipment has come recently into prominence.

With the development of automatic-control equipment the whole aspect of these operating problems changes, since the human element no longer becomes the limiting factor. Analysis of the economies of operation form the basis of preparation of ideal schedules adapted to the particular system requirements, and the application of specially designed automatic-control equipment permits the rigid enforcement of these ideal schedules, eliminating the losses which must result from the inability of operators to follow these schedules continuously.

One of the first applications of this principle of operation was made at the 87,000-hp. Norwood plant of the Carolina Power & Light Company, where the problem presented was to obtain the maximum operating efficiency out of two high-speed, large-capacity units with relatively steep efficiency curves, and one somewhat smaller slow-speed unit of a relatively flat efficiency curve. Design studies showed that with the units of different capacities a higher average efficiency could be realized for the plant over its entire range of output than would be possible if all three were of the same high-speed characteristics. Economic load schedules showing the proper distribution of load between the units necessary

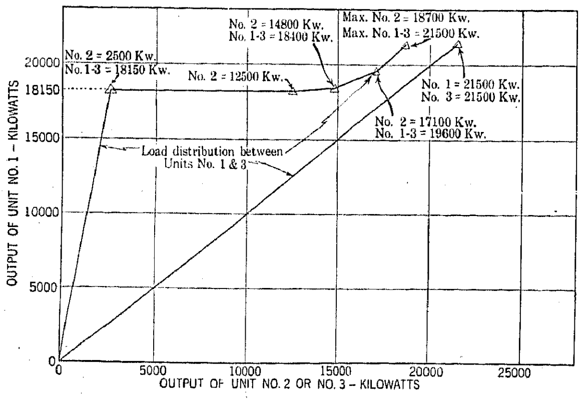


Fig. 1. Ideal loading schedule as calculated for the 87,000-hp. Norwood plant of the Carolina Power & Light Company

to maintain a maximum combined efficiency indicated a rather complex problem; at least from the standpoint of manual operation. It was demonstrated that slight departure from the proper loading schedule would result in appreciable loss in efficiency.

At Norwood the equipment as actually installed consists principally of a multiple bridge circuit, one side of each bridge being a manually-adjusted standard potential and the other side a potential in proportion to the unit output. By basing the standard potential relations upon the ideal schedule for load division between units, the balance would be secured at a point at which the load on the various individual units would be brought to the standard as manually set; this in turn agreeing with the desired load distribution between units. A single dial, subject to the control of the operator, accomplishes an economic load distribution between any combination of units in service. Additional attachments make for more flexible operation but introduce no change in the basic principle involved.

Study of the curves in Figs. 1 and 2 will reveal what application of automatic control can accomplish to relieve plant operators of the burdensome routine; also what can be accomplished by maintaining the highest possible operating efficiencies at the station. The circles show the results of manual operation while the triangles represent the operation with the automatic control in service. In Fig. 2 the upper envelope curve represents the maximum over-all efficiency of the plant and it is of some interest to note how accurately the automatic operator follows it as indicated by the close proximity of the triangle. The approximate figures indicate that in so far as its relation to the ideal operating curve is concerned, on manual control the production efficiency of this station was approximately 90 per cent. With the automatic operator the average operating efficiency has been raised to a point in excess of 96 per cent and has been kept as high as 98 per cent for appreciable periods of time. The difference between the ideal operation represented along the upper envelope curve of Fig. 2, and the actual results secured at the station, include all losses due to the incorrect number of units in service, as well as the losses introduced by maintaining system reserve capacity. The actual loss incurred by incorrect distribution of the load between the units while under automatic control has been materially less than 1 per cent.

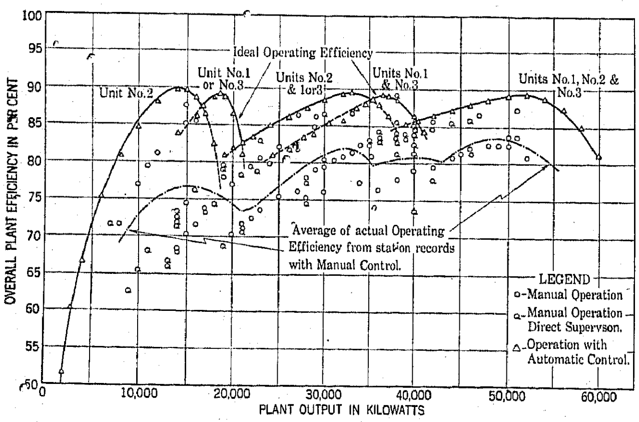

Fig. 2. Over-all plant efficiency curves for Norwood plant

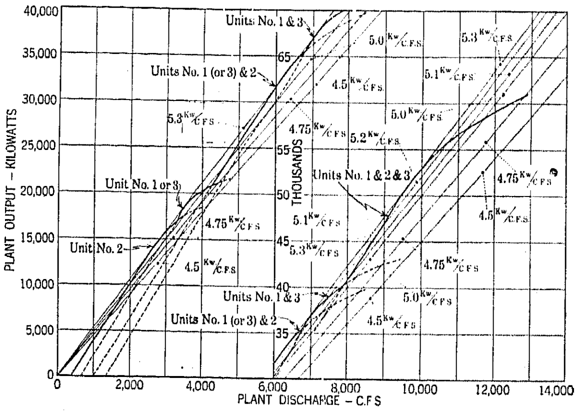

Fig. 3. These curves, showing power output with respect to water discharge, simplify the work of the load dispatcher

At the Norwood station daily efficiency log sheets are carefully kept to furnish the basis of detailed analyses through which the operating engineers may determine the reasons for production losses—accurate records upon which to base their efforts, and by which to direct attention to the elimination of losses.

To simplify the work of the load dispatcher, the curve sheet reproduced in Fig. 3 was prepared representing the station output with respect to station discharge and with superimposed radial lines representing uniform increments of the kilowatts obtainable for each sec-ft. of water passing through the station under the rated head at which the plant normally operates. These radial lines intersect the power-discharge curves at various points, and both the load dispatchers and station operators can see at a glance the zones of desirable operation.

By means of these curves and log sheets, combined with the assurance that whatever load is dispatched to the Norwood station will be carried in the most economic manner possible, the system operators and load dispatchers were provided with a more efficient tool with which to work. This resulted in operating efficiencies and reflected exceptionally large savings to the power company over and above the very best possible with manual operation.

Another interesting application of automatic operator equipment was made more recently at the Morony plant of The Montana Power Company, near Great Falls, Mont. Morony was designed to effect system control and automatic frequency control equipment was installed as part of the hydraulic turbine contract. Both units in that station are of the same size and operating characteristics, and it was estimated that the requirements for maintaining frequency on the Montana system would call for the continuous operation of both units through a range of output from one-half to three-quarters of their full-load rating. As the load on that system is subject to variations not easily predicted, question arose as to the loss of efficiency emanating from the operation of two units at less than one-half of their individual capacities where the load could be more efficiently carried on a single unit.

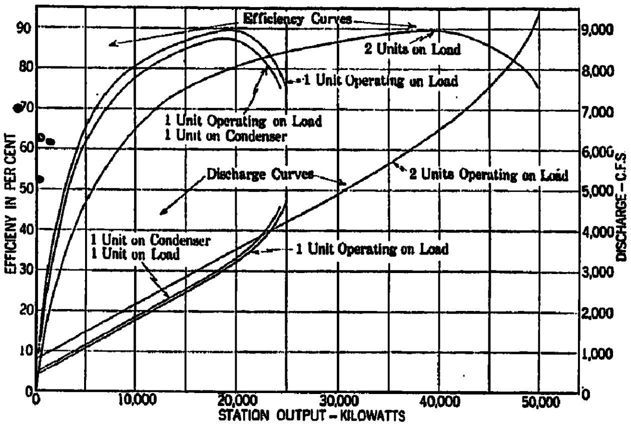

Fig. 4. Performance of the Morony plant of The Montana Power Company under control of an automatic operator

With the application of automatic frequency control to Morony, a further step was made in the development of automatic economy control by arranging special equipment automatically transferring one unit from operating on load to operation as a synchronous condenser, where the point had been reached of one unit alone carrying the particular load demand of the station more efficiently than could the two units together. From Fig. 4 it may be seen that for an output of less than about 23,000 kw. it is more efficient to run a single unit than to operate both units. Under this condition it was impracticable to shut down one of the units because it was necessary from a system standpoint that the surplus power of the two units be immediately available to care for sudden load demands. This requirement led to the development whereby one unit when its generating capacity is not needed is transferred automatically to synchronous condenser operation. By the use of efficient automatic air vents, the power required to drive one unit as a synchronous condenser is held to very small limits, as shown by actual tests and as reflected by the curves of Fig. 4. Provision was made also to return this reserve unit automatically to load service whenever it was required, this to be done either at a very slow rate for normal service, or at a very rapid rate for emergency conditions.

Fig. 5 represents the economic analyses of Morony station with the saving effected by the automatic control plotted with respect to station output. By the operation of one unit as a condenser and one unit on load, based upon the utilization of the same water flow as would be required for two units carrying this same load approximately 24,000 kw. in capacity are saved. According to the latest studies this represents slightly more than $7 per hour saving (3 mills per kw. hr.) for each hour that the plant is operated at an output of less than 18,000 kw. Since storage facilities are available, these same savings can be translated into savings in discharge as shown.

The possibilities of extending this type of control to other applications is at present virtually unlimited. The same principles that have been outlined in connection with the application of automatic economy control to individual plants are readily adaptable to the operation of groups of plants, including a combination of steam-electric and hydroelectric plants.

Application of automatic economy control to electric power generation requires an intimate knowledge of system characteristics as well as prime mover characteristics. The success of automatic economy control installation can reach its highest degree only through complete cooperation between the manufacturer and the operating company and by maintaining an impartial attitude in regard to the equipment to be used, its application and its limits. To secure the ultimate aim of the highest efficiency of power generation possible with the installed equipment the engineering of design and application must be carried on with these principles in view.

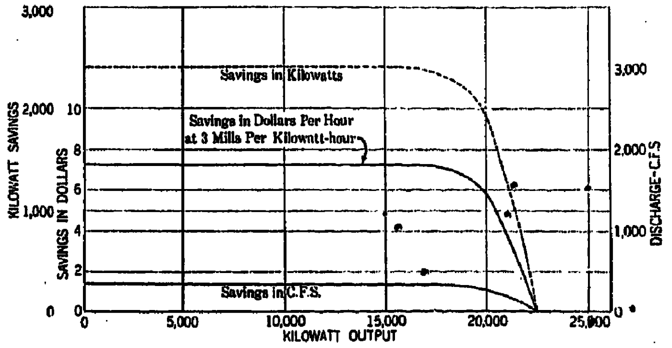

Fig. 5. Automatic operation at Morony translated into savings

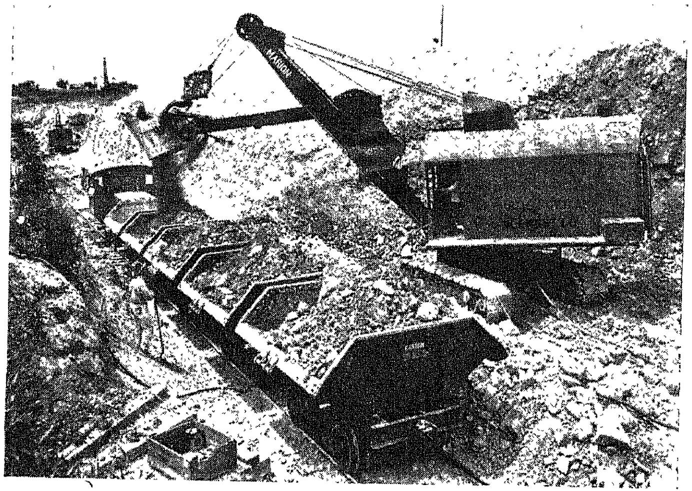
Electricity in the Cement Industry

By R. H. Rogers

General Electric Company
Schenectady



Electric shovel in cement mill quarry

Practically completely electrified, the cement producing industry uses 2½ billion kilowatt-hours of electric energy annually in the production of its $275,000,000 output of 175 million barrels.

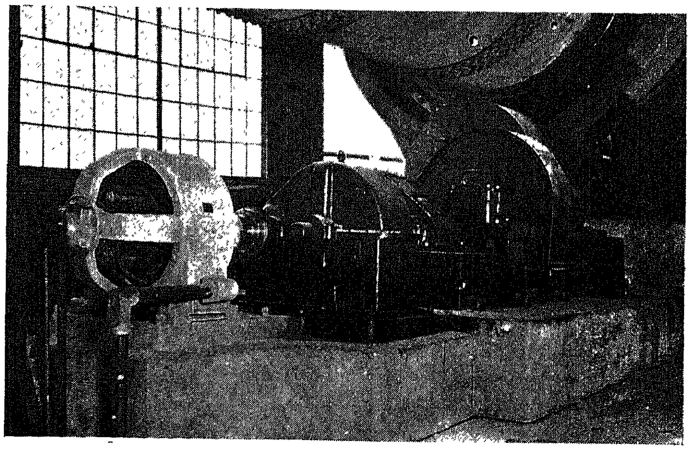
AN INDUSTRY which uses 2½ billion kilowatt-hours of electric energy per year at practically unity power factor, and at the highest load factor known to the larger industries, presents many interesting features to the electrical energy. In the Portland cement industry the use of electric power in new plants is becoming universal. The greater part of it is purchased power and all of it is used subject to extraordinary efforts to get the most out of every kilowatt-hour.

A typical modern cement plant has a daily output of about 3,000 bbl., costs 2½ million dollars, employs some 200 men, and uses from 45,000 to 60,000 kw-hr. each day. The total investment in this highly competitive industry in the United States is some $650,000,000 and the value of its annual output of 175,000,000 bbl. (700,000 94-lb. sacks) amounts to $275,000,000. Major plants of this industry, totaling some 160, are scattered through 33 states in the Union. According to Cement Association estimates, 33 per cent of the annual manufactured product is used for road construction, 25 per cent for building, 15 per cent for rural uses, and the remaining 27 per cent is scattered over some five classifications, the last of which covers bridges, river and harbor works, dams and water power projects, and takes only 4 per cent.

Commercial Portland cement is more or less a varied mixture of tricalcic silicate, dicalcic silicate, tricalcic aluminate and tricalcic ferrite. The alumina and iron oxide act as fluxes so that the lime and the calcium can combine at workable temperatures. Excluding the normal 5 per cent of impurity and the 2 per cent of gypsum added as a retarder, ordinary cement contains about 65 per cent lime, 25 per cent silica, 7 per cent alumina, and 3 per cent iron oxide. Its manufacture involves many operations and electric equipment contributes to expeditious handling and control throughout the processes.

In a typical installation raw materials are taken from the quarry by electric shovels, hauled by electric trains to electrically-driven crushing plants whence the materials go through various grinding, handling, and mixing processes, all electrically controlled. Slurry, the output of the wet process tube mill, is pumped to storage basins and correcting tanks where a chemist maintains the working stock at the desired chemical status.

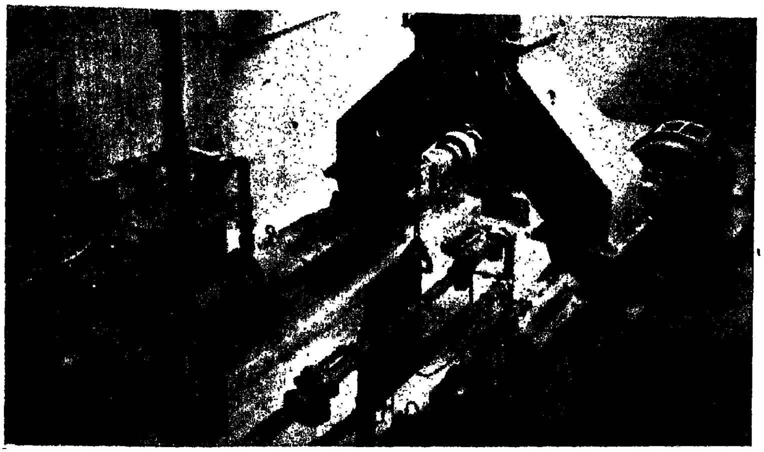
Gigantic tubular revolving kilns, some as large as 12 ft. in diameter, 350 ft. long, and weighing more than 400 tons—by far the largest moving pieces of machinery in the world—receive the slurry for heat treatment. To stimulate a natural flow of its contents, the kiln is inclined at a pitch of approximately ¾ in. per ft. and to keep its contents duly agitated it is revolved at speeds varying from one-half to one rev. per min. About



Adjustable-speed, 75/100-hp., 230-volt, d-c. motor driving kiln through 900:1 reduction gear

---

Presented at the A. I. E. E. Southern District Meeting, Louisville, Ky., Nov. 19-22, 1930. Full text printed herewith.



Cement pumps handling cement from dry grinders to silos; driven by 60-hp. 900-rev. per min. induction motors

three hours are required for the material to pass through the longer kilns from the stack end to the firing end, during which time it meets with increasing temperature up to 2,900 deg. fahr.

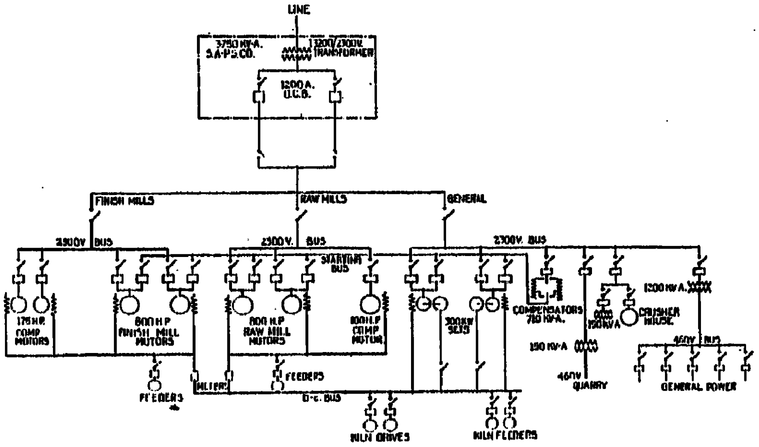
In its passage through the kiln, the slurry is gradually raised in temperature through a zone of chemical reactions to a point of fusion, the product of which is clinker about the size of ordinary marbles. This white hot clinker then passes through long cooling drums to storage where it may be kept indefinitely—even outdoors since it is impervious to moisture. It is hard enough to scratch glass, dark brown or black in color, and bears no physical resemblance whatever to either its raw material ancestors or to the Portland cement which it will be when finely ground.

From the pulverizing tube mill the highly chemically active grey powder—Portland cement—is pumped electrically to storage silos from which it is reclaimed for shipment.

From the central station load standpoint, the cement mill is attractive because it runs through the 24-hour day, often operating as much as two years without shutdown. A plant having a capacity of 3,600 bbl. per day will have a connected load of about 6,500 hp., and the small percentage of idle equipment means a load factor exceeded by few, if any, other industrial loads. Further, the commonly used synchronous motors facilitate power-factor control, adding to the attractiveness of the load. In spite of the fact that waste heat available from the kilns is sufficient to operate a power station of ample size to serve the mill, power usually is purchased. Although many waste heat plants are in operation, advantageous power contracts available in recent years, together with a desire on the part of the cement companies to devote all available capital to the production of cement, have tended to suppress the tendency to install waste-heat boilers and turbine-generating plants.

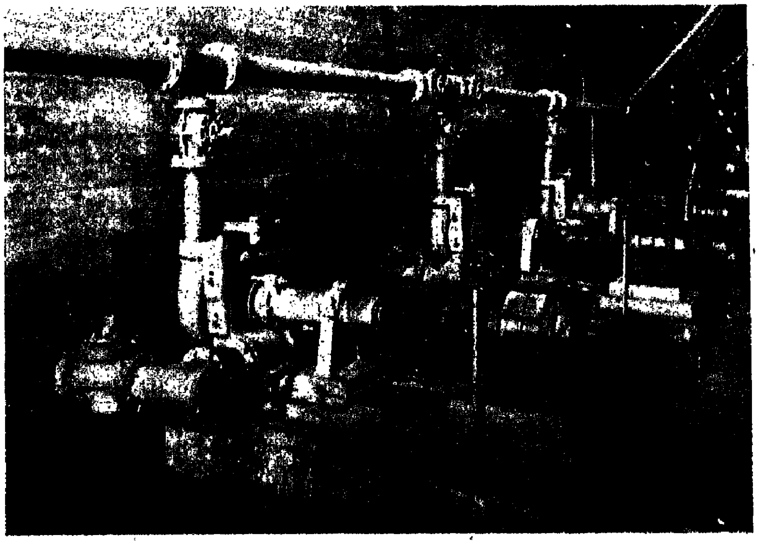
In cement mills at least three common arrangements of electric power distribution are in vogue: (1) A 2,300-volt secondary system with small 2,300/440-volt transformers scattered about the plant at convenient low-voltage centers; (2) separate transformers with 2,300- and 440-volt secondaries placed at the substation; (3) transformers with secondary windings for 2,300 and 440 volts.

The present tendency is to concentrate all circuits at the main switchboard and to control all of the larger motors throughout the plant from that point. Rigid demand specifications common in power contracts make desirable the avoidance of peaks and this is done in some instances by having all heavy motor starting executed by the switchboard attendant, upon signal from the machine operator. This enables the switchboard attendant to watch his demand meter for an opportune moment, a practise which permits full-voltage starting on even the largest synchronous motors, thus simplifying the control and reducing control investment.



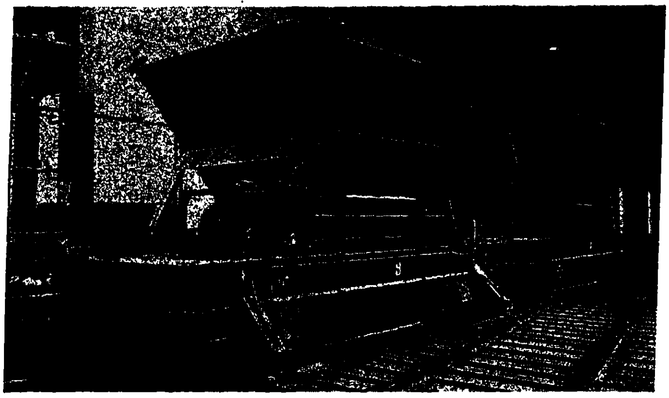
Circuit lay-out used in one prominent 3,600-bbl. mill; arrangements vary widely in different mills

On the main switchboard, some newer mills have installed automatic peak and demand limiters which function by cutting off temporarily certain preferred



Battery of 4-in. slurry pumps driven by 30-hp., 1,500-rev. per min., 440-volt, 25-cycle motors loads when peaks threaten, as well as cutting off larger banks of motors when the 15-min. demand limit is threatened. Air compressors used in a mill may involve as many as four 175-hp. synchronous motors, and solenoid-operated unloading valves are used often to alleviate impending peak conditions for short periods of time.

Another refinement successful in automatically holding the plant power factor at unity is accomplished by arranging the power factor meter to control the field strength on an excitation motor-generator. With a falling power factor this arrangement permits the generator field to be strengthened and the resulting increased excitation on the synchronous motors driving the tube mills tends to restore the desired power factor.



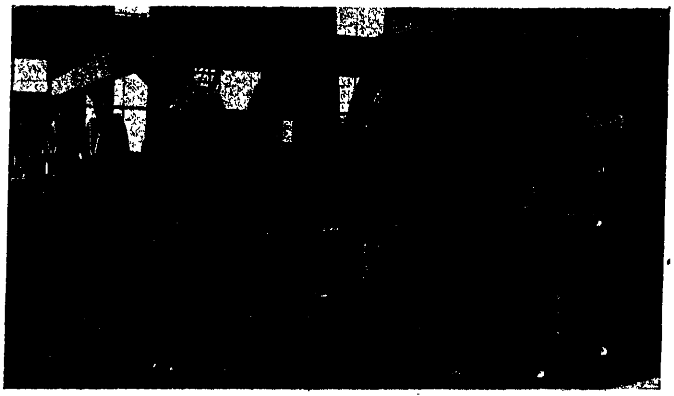
Side-dump transfer cars each operated by two 75-hp. 250-volt motors; motor-driven air compressor on each car

Diverse characteristics of the motor loads in the cement mill make necessary the use of many different types of motors, including adjustable-speed, d-c., wound-rotor induction, squirrel-cage induction, and synchronous motors. For kiln drive and for various types of material feeders requiring a wide range of adjustable speeds, 230-volt, d-c. motors are used. Feeder motors most commonly are 5-hp. open-type units, while kiln motors may be rated at from 50 to 100 hp. Controls for the various motors are concentrated in groups at convenient points so that the kiln operator may control the slurry or dry feed, the coal feed, the kiln rotation, and other related operations.

Electric power shovels are meeting with much favor in cement mill quarries, and those subject to heavy work are almost sure to be operated on generator voltage (Ward Leonard) control. On such shovels there is a motor-generator set, either synchronous or induction, with three d-c. generators, one each for the hoist motor, the swing motor, and the "crowd" motor. Operation and reversals of these motors are controlled solely by the strength and polarity of the fields of their generators, a system which enables the shovel to do a tremendous amount of work in such a smooth way that maintenance no longer is a heavy item in shovel operation. On some properties electric traction is used, and of course d-c. motors carry the burden. Self-propelled side-dump cars, each hauling a trailer, are used at one prominent plant.

Wound-rotor induction motors are used on heavy duty equipment, such as quarry slope hoists, rock crushers, hammer mills and similar equipment, where the current inrush to a squirrel-cage motor would be too great for full voltage starting or where graduated acceleration is desired. These motors are used also for adjustable varying-speed service, such as required for kiln drives, by using constant duty resistors in the secondary circuit. Large motors of this type are operated from the 2,300-volt circuit, while the small ones operate on 440 volts. Squirrel-cage motors of two types are used, but the normal single squirrel-cage type greatly predominates.

In the modern cement mill synchronous motors account for the greater part of the power applied. Normal-starting-torque synchronous motors are used on the d-c. motor-generator sets, air compressors and similar equipment. Tube mills—huge revolving cylinders, in the larger sizes each containing perhaps 100 tons of hard steel balls or grinding pellets in addition to its load of clinker—require from 400 to 900 hp. to drive them at 20 rev. per min. These mills offer a starting load often as high as 160 tons, representing a motor load of from 125 to 180 per cent of normal.



"Super-synchronous" motors provide for full-load starting; the four 800-hp., 180-rev. per min., 2,200-volt motors drive two mills for finish grinding

For this particular duty "super-synchronous" motors were developed. This type has a stator mounted on trunnion bearings and surrounded by a band brake. When it is desired to start one of these excessively heavy loads, the brake is released and the stator brought up to synchronous speed while the rotor and its load are standing still. This makes available the whole normal pull-out torque of the motor for starting the tube mill load and, as the brake is applied gradually, the stator slows down and the rotor speeds up. Of course, the sum of the stator and the rotor speeds always is synchronous speed. After from 10 to 20 sec., as dictated by permissible current limits, the stator is brought completely to rest and the motor thereafter continues to perform as a normal synchronous unit. The brake may be applied either by hand or by a direct-connected pilot motor set to operate at a predetermined rate. In common with the other synchronous motors the power factor of these machines may be adjusted to suit the power factor demand of the plant. Normally, these large motors are started from a reduced voltage bus energized through an auto-transformer or compensator, although in some of the new mills they are started direct on full voltage.

High torque synchronous motors are being applied with good results to tube mills where the power system is adequate to stand the current inrush incident to eight- or ten-second starting. The motors have double squirrel-cage or amortisseur windings, which affect the starting torque and starting current just as the same construction affects a squirrel-cage induction motor. This type of motor presents the simplest form of synchronous motor drive for hard-starting loads, since it requires no clutch or special mechanical construction.

In a 3,600-bbl.-per-day cement mill of modern design there will be about 3,000 hp. in induction motors and 3,500 in synchronous motors. Power factor of the induction motor division will range from 0.82 to 0.85, since all of the motors are fairly high-speed units and carry practically full load, while synchronous motor power factors, of course, are controllable. A common practise in one mill is to operate all of the smaller synchronous motors at unity power factor and to operate four 600-hp. units at 0.90 leading. This results in 3,000 hp. operating at 0.82 lagging power factor, 1,000 hp. at unity power factor, and 2,400 hp. at 0.90 leading power factor.

Continuous operation is of vital importance in several of the steps in the manufacture of Portland cement, and extraordinary precautions are taken to avoid shutdowns. Duplicate units, high class wiring, ample sizes for all equipment, high class supervision and careful maintenance make possible continuous runs of as long as 23 months. After such a period drastic renewals and other maintenance measures are executed to make possible another long and uninterrupted period of production.

Safety to personnel is provided for in the cement industry to a degree not found in many other industries. This attitude is reflected in the entire electrical installation accounting for the prevalance of push-button magnetic control for the mechanical safe-guarding of live parts of motors and control and for the strict enforcement of rules limiting changes or adjustments to electrical equipment to properly qualified persons.

A few years ago cement mills were considered to be particularly hard on electric motors and similar equipment because of the prevalence of abrasive dust. Corrective measures have been so extensive and successful, however, that no extra precautions now are needed to insure successful operation of electrical devices in a cement mill. In fact, motor generators, air compressor motors, large mill motors, and in some cases even the switchboards themselves are installed out in the open in the mill room, a place where in the older mills the dust was the thickest. Today, a cement mill may be made as clean as a food producing plant.

What of the Foreign Job?

In the new and rapidly developing countries lie great opportunities for speedy advancement, so attractive to the young engineer; but forethought is necessary if such a step is to be taken advantageously.

By Percy H. Thomas

Consulting Engineer, New York
Fellow, A. I. E. E.

SOMETHING mysterious, something appealing to the imagination of a young engineer, is to be found in the contemplation of a "foreign job." The idea of going abroad among a group of people perhaps somewhat backward in latest engineering and construction methods, and helping them to create a record-breaking mining plant that will earn large profits; or, to install a far-spread and efficient power system to bring from high mountains electric current for a great city with incidentally a large financial nest egg,—is enough to stir the blood of any young, ambitious engineer. This after all is as it should be.

When, however, a young man with a few years' experience in practical engineering, asks for advice as to whether to seek a job abroad or to stay at home, the impulse is to recommend that he stay at home. For this there are good sound reasons; the chief one, that experience has proved that the goal pictured by the imagination of the young man is seldom achieved. Conditions involved in scoring a conspicuous success in foreign engineering fields are many and exacting, and few men have the requisite qualifications. Not many, however, realize their own limitations, nor the difficulty of maintaining a proper perspective in new surroundings. Once a man is launched in a foreign country on a three-year contract a change of berth is no longer easy. Nevertheless, for the right man this service abroad offers inviting opportunities.

There are two types of service to be considered. In the case of the man from "the States" the simpler and more usual undertaking is the signing of a contract with a large construction or operating company, controlled from the home country—a job somewhere in Mexico or South America. In such a case, the man goes among people of his own kind—speaking the same language, with the same background, and living the same sort of life. All matters of transportation, housing, sanitation and health, and the regularity of pay day are company provisions. The real effect of the situation, however, is to give opportunity for intensive technical work, free from distraction and with a good chance to use ingenuity and resourcefulness in overcoming new or locally adverse conditions. There is a chance to evidence intelligence, grit, and character; and two or three years in a foreign country under usual conditions will go far to develop all these qualifications. It is remarkable how one's personal characteristics are stressed; always liquor temptations must be met, and when abetted by example, homesickness, and physical exhaustion it becomes insidious and hard to resist. The success and promise of many a young man has been destroyed by overindulgence.

Also, away from the society of women acquaintances, it is difficult to satisfy a longing for society. On the foreign job women are few and most of those present are married. With the persons assigned to work with him a man often finds himself thrown with unpleasant and uncongenial personalities; this will be trying and frequently irremediable.

Conditions are usually even more difficult for a man who takes his wife with him, for the limitations of such a life weigh more heavily upon her. Lack of conveniences, absence of the relaxations and diversions to which she is accustomed, and the long distance from relatives and friends, are trying, especially since the woman does not have the stimulus of the job's constructive work. And discontented wives may cause real difficulty. But there is another side to the woman's work on the foreign job; a tactful, good-willed woman can do wonders in brightening up camp life and in organizing social activities. In fact companies depend upon a sufficient proportion of this type to keep the spirits of their men normal.

On a foreign job, advancement in authority and personal development are rapid, and a man may rise far in three years. Ability and adaptability count; and further, a man usually gets a wide variety of experience.

At the end of the first contract, the difficult question arises whether to stay or return home? In the latter case there is usually little difficulty in picking up the home threads, the period of absence not having been great. But for the successful man, with offer of more pay, more responsibility, more interesting work, and a feeling of partnership and loyalty for the enterprise, the temptation to stay is strong. Generally, if a man takes his second contract he has crossed his Rubicon and is likely to have a more or less permanent stay. But if he wishes to marry, the question of finding a wife is a formidable one; some find girls of their own nationality on the job; some marry women of the adopted country, but ordinarily, the choosing is under unfavorable auspices.

When the family begins to grow up, the question of schools increases the difficulty, and usually as they reach their late "teens," the young folks are sent back to the home country. The sequel is that when they arrive at college age or even later, there is effort for the return of the whole family. Then the engineer finds himself out of touch with home conditions and former friends. Very few succeed in placing themselves to advantage, some obtain only inferior positions, and not infrequently, a man with financial obligations must return if he may, to the old job.

It is sometimes supposed that companies pay exceptionally high salaries to engineers going to foreign jobs; this is a mistake, for salaries are likely to be rather less than more. It may be said, however, that on the foreign job it is comparatively easy to save a large part of the salary, and this, in the course of years, may amount to a material sum.

The second type of foreign service is the engineer who goes to stay in the new country; to develop with its life and industry. Only those exceptionally fitted and very sure of their ground should consider this course. At the start it is difficult to picture clearly the process and outcome, but once the die is cast it will be hard to turn back, even though many periods of doubt and regret may arise.

Success will lie in entering whole-heartedly into the life of the country and adopting its ways and ideas; not on sufferance, but with approval and appreciation. In civilization, point of view, mode of living, use of leisure, and so on, the people of a foreign country are apt to contrast strongly and unfavorably with those at home. It should not be forgotten, however, that their customs may be different rather than inferior; that life and happiness are complex, and that after all only a few of the opportunities of pleasure and culture offered anywhere may be embraced. While one life may excel in certain things, another may lead in others. Genuine success must be based upon accomplishment, friendships, and appreciation of one's neighbors. Human nature is the same the world over and it is a fact that if one treats people kindly, appreciating their good points, assisting in their enterprises, training oneself in their language, studying their literature, and being generally sympathetic, the reward will be ample.

It is the new and rapidly developing countries wherein lie the coming generation's opportunity for service and advancement. Splendid possibilities for competent individuals as representatives of home companies exist in foreign countries, but to hold the confidence and sympathy of the native men of affairs and at the same time serve the best interests of the home company is no mean achievement.

Small Alternators now Fully Automatic

By Earle R. Wetzel

Electrical Engineer, Kohler Co., Kohler, Wis.
Associate A. I. E. E.

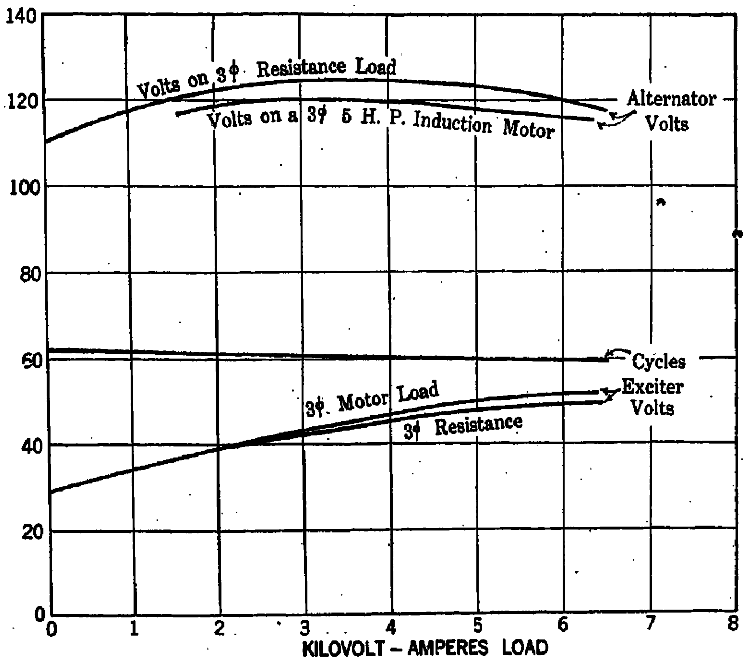
FULL-AUTOMATIC alternators with inherent voltage regulation are now available in 5- and 10-kv-a. sizes. These units have been designed especially to be used in connection with small engine-generator plants where an a-c. supply is desirable. With this equipment a distribution system may be of standard two- or three-wire construction in which every switch operates as a remote-control device for operating the plant without special control circuits.

In the design of this machine difficulties formerly met in connection with inherent regulation have been overcome. Armatures for both alternator and exciter are mounted on a common shaft carried on a single set of bearings. Further to simplify construction the two sets of field poles are mounted in a single frame. The resulting combination machine has a voltage regulation nearly the equivalent of a compound-wound d-c. generator, and achieves this end without manual or sensitive automatic devices.

The two armature cores are built from standard laminations and assembled on a common shaft with slots in approximate alinement. Each exciter armature coil is form-wound with a definite number of long and short turns with a continuous conductor. Short turns are lap-wound in the usual way in the exciter slots only, while the extensions constituting the long turns are laid simultaneously in the alternator slots. Alternator slots are only partially filled with the long coils from the exciter armature and in these slots, the alternator coils are assembled subsequently in any voltage or phase relation desired. The two sets of windings are insulated from each other, and therefore the two voltages are independent.

In operation with zero current output from the alternator, the exciter voltage is the vector sum of that generated by the exciter windings revolving under two sets of field poles. Each alternator field pole is opposite in polarity to its adjacent exciter field pole and displaced approximately 40 electrical degrees in the direction of rotation. There is therefore a differential action of the generated voltage in the extended exciter armature coils as compared to that portion in the exciter armature slots. Any weakening of the alternator field reduces this differential voltage, permitting the exciter voltage to rise somewhat proportionately.

Double armature assembly of 5- and 10-kv-a. full-automatic alternators



Voltage curves of three-phase alternator-exciter unit for various loadings. All curves at running temperatures and with increasing loads; voltage of cold plant about 130

It should be realized that any alternating current in the alternator coils is in synchronism with the respective field magnetism in such a way that the extended exciter armature coils receive their magnetic flux resultant from that of the alternator field poles and the ampere-turns of the alternator coils in the same slots. This change in the relation of voltages generated in the two sections of each exciter armature coil gives the effective compounding desired, and the angular relation of the two sets of field poles decreases this differential or bucking action on low power factors with a corresponding rise in exciter voltage.

To maintain stable exciter voltage over a wide range of alternator loads without extreme magnetic saturation on the heavier loads, the exciter voltage increases approximately 50 per cent on full alternator loads, with a possible 100 per cent rise when starting large polyphase motors. Effective compounding can be altered, if necessary, with an adjustable resistance in the alternator field circuit.

While this system of voltage regulation may serve only small alternators of low voltage, it is machines of this capacity which do not receive technical attention in service. Full-automatic operation necessitates automatic voltage control.

Insulation Research Turns Again to Fundamentals

After digression to follow specific channels of commercial stimulation, insulation and dielectric research is finding that known facts can be interpreted correctly only with fuller knowledge of underlying fundamentals.

AN IMPOSING array of subjects pertaining to the research being directed toward improvements in and a better understanding of electrical insulation was presented at the third annual conference of the Committee on Electrical Insulation of the Division of Engineering and Industrial Research of the National Research Council. This conference was held at the Bureau of Standards in Washington, D. C., Nov. 7-8, 1930, and attracted the attendance of more than a hundred physicists, chemists, and electrical engineers.

It was of particular significance to note that the trend of research effort in this field is definitely toward a better understanding of fundamentals. This gives rise to hope that the proponents of the three widely held and largely incompatible theories—(1) dipolar molecules, (2) anomalous conduction, (3) colloidal assemblages—may find common ground for an understanding. At the present time none of the theories held really satisfactorily explain the insulation problems faced by the practical electrical engineer.

In an attempt to present something of a cross-section of the activities reflected at the Washington conference the annual report of Doctor J. B. Whitehead, its chairman, is presented herewith practically in full and abstracts of reports of several of the specific studies are presented on the following pages.

Year's Efforts Show Commendable Progress

By Dr. John B. Whitehead

The John Hopkins University, Baltimore
Fellow, A. I. E. E.

RESEARCH and development in the field of dielectrics and insulation have resulted in notable progress during the past year. Experimental studies have ranged from fundamental questions in the fields of pure physics and chemistry, through the important intermediate field of effort made to bring together the talents, resources, and enterprise of both pure and applied science to the wide and always active field of direct development by cut-and-try methods for the improvement of insulating materials and structures.

LIQUIDS

In the class of fundamental studies those of perhaps most direct interest are the studies of dielectric constant in liquids, with particular reference to molecular orientation and the contribution of this phenomenon to the resulting polarization. Of special interest is the increasing discussion of polar molecular orientation as an explanation of dielectric loss under alternating stress. Another important group of studies is on the relation between fundamental chemical structure as varied through a series of liquid isomers and their corresponding electric and other physical properties. Several independent researches of this type now are under way. Interest in these two groups of problems is general, not only in this country, but also abroad. More than any others, they give promise of further knowledge of the ultimate structure of the dielectric molecule. Closely related studies are those on the conductivity encountered in commercial insulating liquids and its relation to alternating stress. These liquids often excel in electrical properties, the purest used in physical research and obey much the same laws. In these cases the laws of conductivity are found to vary widely as related to both electric stress and duration of application, both having immediate bearing upon the amount of loss under alternating stress. Several theories have been proposed as to the origin and nature of the several types of ionic carriers apparently present in these phenomena.

CRYSTALS

Important fundamental studies are being directed also to the problems of solids as exemplified in crystals. Their relative freedom from impurities gives favorable opportunity for study of the nature of their residual conductivities, polarization electromotive forces, ultimate electric breakdown strength, and other allied properties. One result of this work has been to show that the structure of even the purest crystals of any considerable size is not so uniform as supposed, and that irregularities and faults often play an important part in the electric behavior of even the best of these materials.

BREAK-DOWN STUDIES

In the intermediate class of studies in which effort is made to combine fundamental knowledge and technique with the problems of practise, there is a remarkably wide range of studies on the breakdown strength of gases, liquids, and solids. Development of the cathode ray oscillograph has extended the range of the intimate observation of short-time phenomena enormously. As a result, in the case of gaseous breakdown, early apparent discrepancies between the results of observation and the indications of Townsend's theory of secondary ionization are now through the recognition of other influences in a fair way of being removed. Chief among these is new evidence as to the importance of space charge resulting from the initial stages of ionization, in setting up new and higher values of local electric stress. The importance of these phenomena in their relation to the shape of discharge electrodes has been recognized with resulting indications for improvement in the breakdown strength of the various flashover gaps of practise.

There have been several series of careful investigations of the conditions surrounding the breakdown of liquids ranging from those of simple type such as hexane, pentane, and xylol, to transformer oil and other commercial insulating liquids. These studies present much new evidence on the influence of temperature, pressure, and shape of electrodes, and particularly of the conductivity as a measure of the dissolved impurities. There is recent evidence that a variation of breakdown voltage with pressure may be entirely attributed to impurities.

Many studies on the breakdown of solids have been reported, mostly from German sources but with one interesting group in this country. Efforts in all this work are directed largely toward a closer control of temperature and field distribution. Results always point to a separation of several possible types of breakdown, notably the simple electric breakdown as based upon molecular structure, and thermal breakdown resulting from temperature increase of conduction in its influence as ionizing agent or directly on molecular breakdown through increased kinetic activity.

CONDUCTIVITY OF INSULATING LIQUIDS

Other studies in the intermediate group referred to are those of the conductivity of insulating liquids with special reference to the modification of their properties through mixtures. An example is an interesting proposal which traces the residual conductivity always found in insulating oils to the presence of colloidal particles always present in such oil. These particles have high powers of absorption which converts them into large, heavy ions. Their action jointly with ions of other types may be invoked for explaining several well-known, but hitherto little understood, peculiarities of liquids of this class. Supporting the suggestions of several speculative studies in this field, the presence of space charges in liquids also has been shown with associated variations of potential gradient. In accordance with indications of this type, it would appear that all liquid insulators, even the best, have a small residual conductivity due either to dissociation or to extraneous radioactive influence, but that this conductivity has relatively little influence upon their behavior as insulators. More important is a superposed conductivity due either to residual impurities or perhaps to partial molecular instability, which results in a larger and heavier type of ion that plays its part in the formation of space charges and particularly in the short-time conductivity which reflects itself in dielectric loss.

Another group of studies of liquids are those directed toward the stability of the ultimate structure as revealed under the influence of corona discharges, high stress, cathode ray bombardment, and the like. The gases involved and the residual products are looked to for indications of the nature of the deterioration process in insulating oils.

HIGH-TENSION LINES AND CABLES

Also covering an extension range, the third broad group of development studies involves direct experiments on the improvement of known insulating materials and methods, and the discovery of new ones. Improvement of insulation for overhead high-voltage lines heretofore has not engaged the attention of the National Research Council's committee on electrical insulation; nevertheless it is an active field from the standpoint of insulation and there is a continued study by its own group of specialists. In this direction conspicuous results have been obtained recently in increased knowledge as to the importance of the mechanical design of terminals and flash-over distances in their influence upon the distribution of electric stress and breakdown voltage. Here, progress is directly related to the more fundamental work on the breakdown of gases already discussed.

Problems presented in impregnated paper as applied to high-voltage underground cables comprise another extremely active field. Studies in this field range from the original structure, manufacture, and resulting properties of paper, through a broad series of problems in impregnating oils, into the methods of impregnation and assembly. Another group concerns itself with modifications of the mechanical setup of the cable structure itself—all looking to higher stresses and longer life. Among the more important accomplishments are increased knowledge as to the stability of oils, the separation of the component losses in impregnated paper, better understanding of internal ionization, and many others.

Several investigations—usually accelerated life tests

—as to the influence of residual air and residual moisture in cable insulation are under way. In this connection, problems demanding solution include a suitable accelerated life test on small samples and the law connecting life with voltage and time. Less attention apparently has been given to the question of wax formation in cables, which still remains unexplained. Many improvements in both electrical and mechanical characteristics of various materials for relatively low-voltage insulation have been announced. Noteworthy reports have been made of non-lead-covered insulation for underground service and of rubber insulation having corona-resisting properties.

Increasing evidence of the advantages of oil-filled cable must be given conspicuous mention. Originally developed for the highest voltages, its value in lower ranges now is recognized largely because of the simplification of joints, terminals, oil-feed, impregnation, and other features.

Reference to all this progress would not be complete without mention of the agencies in this country responsible for it. Universities, government agencies, national scientific bodies, manufacturers and public utilities are all uniting in the attack. Each fitted for special types of investigation, their joint efforts insure a steady advance in knowledge.

REFERENCES TO CURRENT LITERATURE

For the convenience of those who may wish to view first-hand the contemporary published record of information that has come to the attention of Doctor Whitehead during the past year, and upon which some of his conclusions are based, the following list is given:

Conductivity of Insulating Oils

PAPERS by Doctor J. B. Whitehead and by Prof. K. F. Herzfeld present further results from the extended program of research under way at Johns Hopkins University on the fundamental properties of insulating liquids, with special reference to their use for the impregnation of paper. The general course of these studies has indicated that within the normal operating range of temperature the dielectric loss in insulating oils of the better known types can be entirely accounted for by the conductivity as measured for the very short time intervals corresponding to the period of commercial alternating circuits. In the case of impregnated paper, dielectric loss is entirely accounted for by dielectric absorption as measured under continuous potential. Doctor Whitehead's paper is a further study of the short time conductivities, and has revealed for the first time the presence of dielectric absorption in a liquid. The influence of this on dielectric loss is examined. His own abstract follows:

"Continuous-current characteristics of several insulating oils are studied for time intervals beginning 0.001 sec. after the application of voltage or short circuit. Essential equipment is the amplifier oscillograph in connection with a quick-acting switch. It is found that in one group of oils there is an initial conductivity which is constant over the period of the first second following the application of the voltage. Thereafter there is a slow decrease of conductivity to a final value much lower than the initial value. It is shown that this initial constant conductivity is sufficient to account for all of the dielectric loss under alternating stress.

"In another group of more carefully refined and deaerated oils there is superposed upon the brief initial constant conductivity a still shorter initial evidence of dielectric absorption. During the first few thousandths of a second the charging current decreases sharply; is followed thereafter by a constant conductivity up to about one second, and thereafter decreases further to a much lower value after a long time. The initial absorption period has a corresponding discharge curve on short circuit. The measured value of the alternating loss in this case is completely accounted for by the sum of the loss due to the initial period of absorption in combination with the succeeding short-time-constant conductivity.

"Other results are presented on the variations of the initial and final conductivities with the voltage and with temperature. The final currents show saturation characteristics, but the initial high conductivities do not."

In Professor Herzfeld's paper are given results of a mathematical study of Prof. Whitehead's results, looking to a determination of the size and character of the ions involved in the anomalous conductivity of these oils. This question has direct bearing upon the problem of the change in electrical behavior and characteristics of impregnated paper as related to those of its two constituents. Studies of this question also were described in a separate paper, presented at the same meeting by Doctor W. B. Kouwenhoven. Prof. Herzfeld's abstract follows:

"It has been shown in a previous paper how the methods developed in the study of conduction of electricity through gases could be applied to determine the nature of the ions present in liquids and solids. In the present paper these methods have been applied to the measurements (recently performed by Whitehead and Marvin) of the space charge set up in insulating oils by a steady electric field. The procedure is the following:

"The shape of the curve shows that the current must be considerably below three-fourths of the saturation current. It is possible to fit the curve closely by assuming the Langevin constant to be $\beta = 36 \pm 10$. From this the number of ions present in the normal state and their mobility can be calculated, which turns out to be $3.5\ 10^{-6} \pm 50\% \ \frac{\text{cm.}}{\text{sec.}}$ per $\frac{\text{volt}}{\text{cm.}}$. With that assumption the mobility is of these ions inversely proportional to the viscosity; mobility in water would be $1.2\ 10^{-4} \frac{\text{cm.}}{\text{sec.}}$ per $\frac{\text{volt}}{\text{cm.}}$ or, in the usual units, 12. If one assumes that Lorenz's results for organic ions can be applied, these ions should have approximately 110 atoms. From the boiling point of the oil one would conclude that the molecule of the oils contains about 45 atoms."

Impregnated Paper Insulation

By F. Hamburger, Jr.

Johns Hopkins University, Baltimore
Associate, A. I. E. E.

THIS abstract of a preliminary report gives some results of a study of the life of impregnated paper insulation under way at the School of Engineering, Johns Hopkins University. The work is being supported by the subcommittee on impregnated paper-insulated cable research of the National Electric Light Association. In an earlier work under the same auspices, a study was made of the influence of residual air on dry impregnated-paper insulation. Results of that study (Vol. 47, No. 1 TRANSACTIONS A. I. E. E., January, 1928) showed the desirability of investigating the effect which different amounts of residual air would have upon the life of impregnated paper insulation. A brief summary of the results so far obtained is given here in the form of eight conclusions, briefly qualified.

LIFE-PRESSURE RELATIONS

A series of accelerated life tests were made on more than 135 samples of impregnated paper insulation in which the only variable was the amount of residual air. Results of this extensive series of tests led to the following conclusions:

1. The life of impregnated paper insulation increases steadily with a decrease in the amount of residual air.
2. The life of impregnated paper insulation decreases rapidly impregnation pressures above 2.5 cm. Hg., absolute pressure.
3. For pressures below 2.5 cm. the normal variations in structure of the samples, particularly tightness, are more important than the amount of residual air.

The pressure range from 40 cm. to 2.5 cm. studied with one compound showed an increase in life from 150 to 2,370 hr. A second compound was used to investigate the pressure range from 2.5 cm. to 2 mm. and in that region the decrease in pressure was accompanied by an increase in life from 4,159 to 6,370 hr. In addition to these conclusions as a direct result of the tests, the necessary preliminary work led to the development of a satisfactory type of sample and reenforced ends for use in accelerated life tests. Several other interesting features have come out of the work which will be treated briefly here.

VOLTAGE-TIME RELATIONS

Accelerated life tests were carried out by means of a step-test in which several different voltages were used. A typical example of the step method used on a number of samples is as follows:

400 Volts per mil for 22 hr.
500 Volts per mil for 22 hr.
600 Volts per mil for 112 hr.
700 Volts per mil to breakdown

Since the step-test was used it was necessary to have some method of correlating the lives of the samples at the different gradients of the test. Investigation led to the adoption of the so-called "eight-power law" as a mode of comparison. From the experience obtained in this connection the following conclusion was reached.

4. The so-called "eight power law" is sufficient for making correlations in such tests as these but leads to unreasonable results if an attempt is made to use it to predict actual life from accelerated tests.

CABLE COMPOUND DETERIORATION

Of the two cable compounds used the first supply was put up in five-gallon cans sealed under vacuum at the refinery. Some of this compound was not used until after it had stood in the containers for seven or eight months; when it was used a marked deterioration was found to have occurred. The second shipment was supplied in 50-gallon drums and was protected from air by the presence of carbon dioxide. Over a period of nine months this compound showed no deterioration. Hence, the conclusion reached is:

5. Cable compound deteriorates even if it contains only a small amount of air, in spite of its being kept in sealed containers. Air should be entirely excluded to avoid deterioration.

POWER FACTOR CHARACTERISTICS

Power-factor characteristics were followed carefully throughout the life-test work; such observations have led to the conclusion:

6. Power-factor characteristics such as the variation of power factor with respect to voltage, power-factor variation with respect to time, or the absolute value of power factor give no indication of insulation life.

PREDETERMINATION OF INSULATION LIFE

The first period of voltage application during the life test, usually 22 hours at 400 volts per mil, was accompanied in almost every case by an increase of power factor. This initial power-factor rise seems to bear some relation to the life of the insulation and leads to a fair correlation which seems to be worthy of calling to the attention of workers in the insulation field. The conclusion drawn is:

7. Power-factor rise due to the initial application of voltage during a life test may be a criterion of insulation life.

This point seems worthy of further study.

Predetermination of Cable Deterioration

IN abstracting his report "The Predetermination of the Deterioration of Impregnated Paper Insulation," D. W. Roper, Commonwealth Edison Company, Chicago, says:

"All specifications for impregnated-paper-insulated, high-voltage cables, both domestic and foreign, are defective in one respect; namely, they do not insure the stability of the insulation under normal working conditions. Several suggestions have been made in this country and abroad, and the Commonwealth Edison Company has tried all of these tests on samples of 66-kv. single-conductor commercial cable made in the past few years, and it has also tried a few new methods of its own devising.

"While these tests, which have continued over a period of more than two years, have resulted in securing some interesting technical and scientific information, up to the present time they have not discovered any test which could be made within the span of few days, and yet be sufficiently accurate to be included in cable specifications as a test for stability of the insulation."

Chemical Research in the Field of Dielectrics

CHEMISTRY is playing an ever-increasing part in insulation practise. F. M. Clark, General Electric Company, Schenectady, chairman of the subcommittee on chemistry, in abstracting his report, says:

"During the year 1929-1930 there has been unusual activity as reported in the journals covering the chemistry of insulating materials. While major interest has centered in molecular phenomena, the chemistry of insulation testing and the development of new materials has not been neglected. There has developed both in this country and abroad a decided tendency toward the gaging of insulating materials on the basis of chemical aging rather than placing principal reliance on the initial characteristics. This demands improved testing methods. The determination of acidity in both paper and oil by electrometric rather than by colorometric analysis has given the insulation engineers a more satisfactory tool.

"The problem of rating mineral oils for transformer use is still unsolved. Sludge accumulation tests slowly are displacing the older tests based on the formation of first traces of sludge. No decision for or against oxidadation under voltage has been made. Studies in the dielectric behaviour of organic liquids such as oil under varying types of electric discharge or under varied conditions for dielectric strength and the relation of these properties to the chemical nature of the material tested should go far in determining the characteristics and the development of new types of liquid dielectrics. The type of discharge has been found to have but little effect on the products formed from the vapors of hydrocarbons, alcohols and organic chlorides. Recent work on the importance of impurities in oil has confirmed the older research results.

"Continued researches during the year have substantiated the hysteresis phenomenon noted in the water sorption curve for paper. The desorption moisture contents are higher than the absorption, due, it is believed, to changes in micellar surfaces of the cellulose. The adsorbed water molecules are held by residual valences. In cotton, the hydroxyl of the cellulose holds adsorbed water. Acetylation of the cotton therefore should result in decreased water adsorption, a prediction in accordance with experiments.

"That the breakdown of solid dielectrics is fundamentally electrolytic in nature is gaining considerable recognition. Whether electric breakdown is thermal or an ionization effect depends according to the newer ideas on the conditions of test. Secondary chemical changes in the dielectric itself or the testing medium may be of major importance in determining dielectric failure.

"Continued study of molecular phenomena during the year has given added confirmation to Debye's theory. Deviations in most cases have been due to the effect of neighboring molecules. Pronounced polarity is doubtless a factor in chemical behaviour, but a large portion of the polarities, assigned by various electron theories of valence, must not be considered as a physical fact but rather as a pragmatic representation of chemical behaviour.

"Careful study of the dielectric constant of organic materials is being pursued to determine changes in both chemical and physical properties. Crystalline formation in inorganic oxides has been shown to produce a drop in dielectric constant. Changes in the dielectric constant of amorphous substances have been approved to indicate crystalline formation. With the recognition of such changes, the synthesis of materials especially designed for the purpose may well be expected as the next step."

A bibliography listing 68 references to current material concerned with the chemical side of insulation research was presented as part of the report of which this is an abstract. Mimeographed copies of that bibliography may be obtained upon application to the Editorial Department, Electrical Engineering, 33 West 39th St., New York, N. Y.

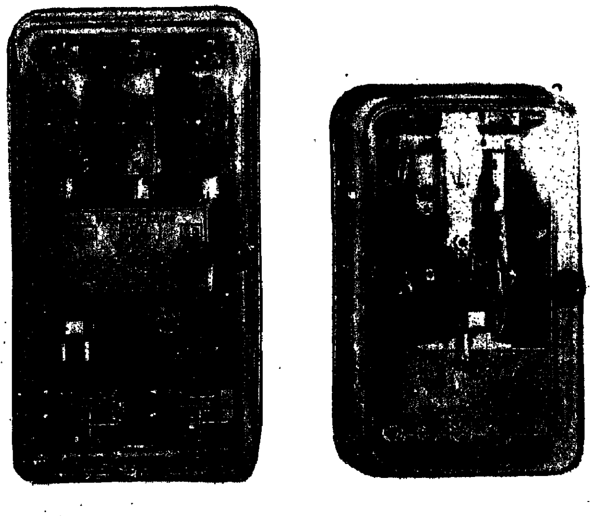
Relays to Operate in One-Sixtieth Second

A WHOLE new family of quick-thinking, fast-acting relays which operate in a single cycle, and base their decisions not on the customary time elements, but upon comparison of instantaneous values has appeared this year. Together with high-speed circuit breakers, they represent the modern view that continuity of service is best assured by cutting off troubles as fast as possible. All these Westinghouse relays act in one-sixtieth of a second—three to ten times as fast as has been customary.

The *HZ* relay on the left of the illustration, in case of trouble on long transmission lines by means of a little wattmeter element perceives within one cycle which way the fault current is flowing, and estimates the distance to the fault by balancing this current against the voltage drop from the station to the short circuit, thus measuring the impedance.

Transformers or other connected apparatus which develop internal disorders are removed from the system by the *HA* differential relay without the rest of the system being disturbed by the opening of other relays.

High-voltage systems are frequently annoyed by grounds, and this is the specialty of a third high-speed relay; it operates on a comparison between the relative direction of residual line current and current in the



These relays operate in a "split second" grounded neutral of power transformers and is both extremely simple and fast.

Parallel transmission lines have an understanding friend in the *HD* relay at the right. It not only sectionalizes the proper line in the twinkling of an eye, but thoughtfully doubles the tripping value of the line left in service. It operates upon a comparison of the sum and difference of currents in the two lines.

Tennessee Lightning Investigation Continues

Test results indicate that only one conductor of a line is involved in any one direct stroke; often is one adjacent to approaching storm.

By J. Elmer Housley

Knoxville Power Company,
Alcoa, Tenn.
Associate A. I. E. E.

WITH the general acceptance of the cathode ray oscillograph in 1928 for field investigations of lightning, a cooperative research was undertaken jointly by the Knoxville Power Company and the Westinghouse Company, for which two field laboratories were established near Alcoa, Tenn. The factors governing the selection of this location were the great number of thunder storms and the existence there of a heavily-insulated tower transmission line with two circuits, operating at 150,000 volts. The profile of the line varies from 700 ft. to 2600 ft., following a rugged country with several long river crossings.

The configuration of the cables is vertical on the double-circuit towers with the middle wire 4.5 ft. toward the tower and a vertical separation of about 12 ft. between wires. The single-circuit lines have a horizontal configuration with 17.5-ft. spacing.

The suspension insulators are composed of 10 disks, and the dead-end assembly of each of the triple strings have 12 disks. Horn-gaps are used on the line and ground side and a horn is placed on each side of the insulator string over the axis of the cable in suspension units, and above the insulator in horizontal strings. A half-inch steel ground wire is common to both types of towers.

Cathode-ray oscillograph and related equipment in field laboratory

The stations were located near tower 70 and tower 93 respectively, but the former was too remote from the storms at the ridge of the mountain and will therefore be discontinued.

Three klydonograph installations were established in conjunction with each station. All klydonograph potentiometers were of the three-phase type, one was located adjacent to each station and one on either side of the stations one mile distant. This is illustrated below. The klydonographs are equipped with eight-day clocks and the film records are removed weekly.

The station at tower 70 is a frame building lined with heavy grounded wire screen, and at tower 93 is a sectional steel building grounded at several points.

The equipment in each station is identical. A gasoline-driven 15-kv-a., 110-volt, three-phase, 60-cycle, a-c. generator supplies power for station use. The direct-connected 1-kw. exciter furnishes 125-volt direct current for use in the concentration coils on the oscillograph.

The Norinder oscillograph with its axuiliary equipment, consisting of vacuum pump, switchboard, linear timing device, oscillator and high-voltage rectifier has been used throughout the tests and many improvements have been made in the apparatus and increased reliability has been obtained.

Three-phase potentiometer and Klydonograph installation for lightning studies

---

From "Lightning Investigation at Alcoa, Tenn.," presented at A. I. E. E. Southern District Meeting, Louisville, Ky., Nov. 19-22, 1930.

The small number of oscillograms obtained since the stations went into operation do not give a complete picture which would enable an analysis to be made of the waves appearing on the line with their exact point of origin and probable voltages which existed there. The data obtained and observations made during the past three years have been valuable in relation to the development of the cathode ray oscillograph and demonstrated the importance of this device in the field.

Since the location of storms must be very close to the station, chance plays a large part in the volume of data obtained. Accordingly it is hoped that by continuing the investigation over a period of time that a sufficient number of surges will be recorded so that a complete analysis of them may be made. Low-resistance tower footings and ground wire were indicated as desirable for decreasing flashovers.

Lighting Airway Beacons

High-tension transmission lines may be tapped directly, through the use of a capacitor potentiometer device to supply as much as 3 kw. of electric energy for isolated airway stations.

By F. W. Cartland

Capacitor Engineer,
Westinghouse Electric & Manufacturing Company
Associate A. I. E. E.

RAPID PROGRESS of aviation during the last few years has emphasized the need of adequately lighted airways. Airports have been located near the cities where electric power for floodlights and searchlights was readily available, but the supply of power to airway beacons in isolated places has been a more difficult problem. Beacons in such localities have been operated from low-voltage transmission lines or where these were not available, gas engine-driven generators have been used. The power required for such installations is approximately 2 kw., and low-capacity transformers are available where the system voltage does not exceed 23,000 volts. When higher voltage lines are encountered the smallest standard transformers built vary from 15- to 100-kv-a., increasing with the system voltage. A 100-kv-a. transformer used to deliver only 2 kw. is not only expensive but also inefficient.

A paper presented by Messrs. Spracklen, Marshall, and Langguth at the Winter Convention, February 13-17, 1928, described a potentiometer device for use with condenser type bushings, which supplied sufficient power for operating relays and synchronizing equipment. With the development of high-voltage outdoor capacitors of the suspension type, came the possibility of adapting them to a potentiometer circuit which would supply greater amounts of power than obtained from a condenser bushing. While the capacitor could be thus used to supply very great quantities of low-voltage power, the capacitors as built at present are of such size and construction that it is not considered desirable or economical to obtain more than 2 or 3 kw. from such a circuit.

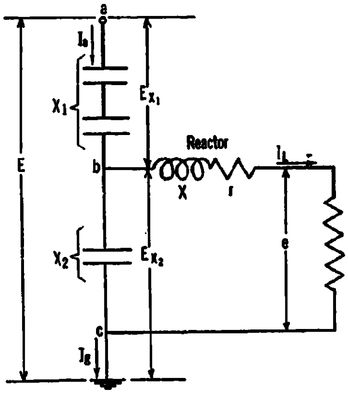

Fig. 1. Theoretical circuit, single line to ground

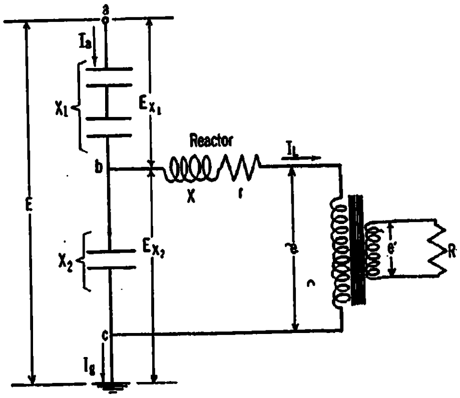

Fig. 2. Single line to ground using small transformer

The capacitor power supply or "capacitap," consists essentially of a number of suspension type capacitors connected in series with a portion paralleled by the load and a reactor in series (Fig. 1). Since in most cases voltage at the load is 110, considering capacitor economy, the use of a small transformer (11,000/110) as shown in Fig. 2 is more desirable. Considering circuits which produce the same voltage regulation, another

---

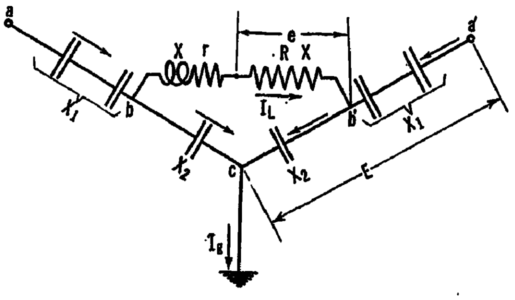

Fig. 3. Theoretical circuit, double line to ground

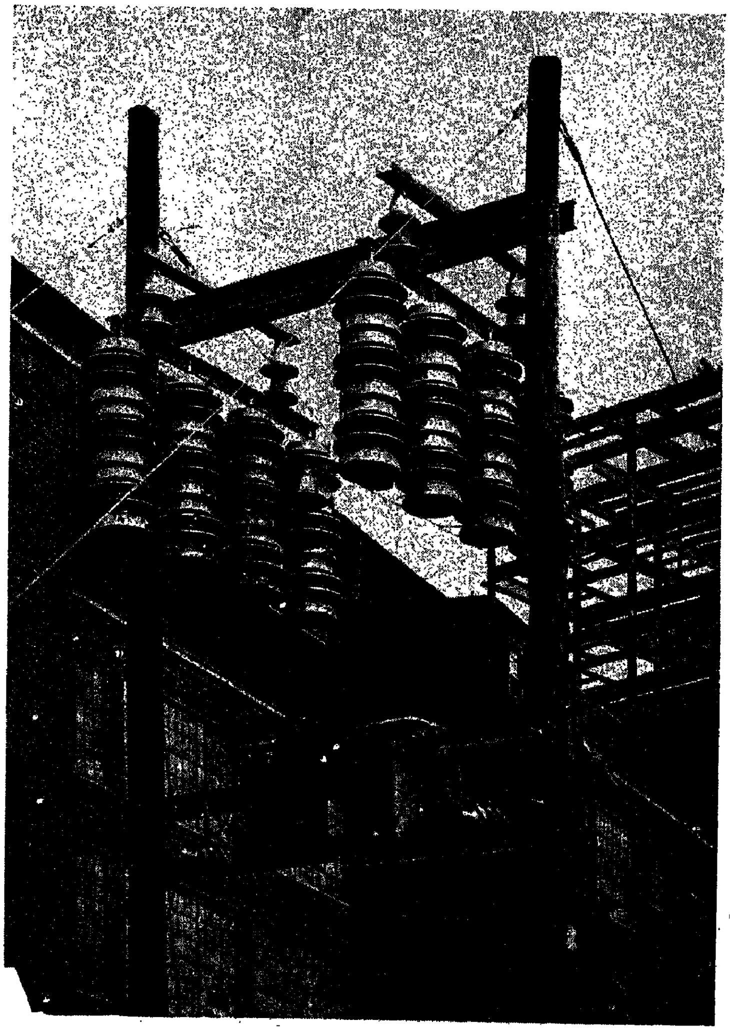
modification of this circuit, as shown in Fig. 3, has an additional advantage in that the full-load ground current is much less than that of the equipment shown in Fig. 2.

A capacitap as shown in Fig. 4 was built for studying the performance and practicability of this circuit. The equipment, built for supplying 2½-kw. unity power factor at 110 volts from a 66-kv. line, had load voltage curves as shown in Fig. 5. The curve of Fig. 6 shows the result of varying the size of reactor. The complete circuit as shown in Fig. 7, consisted of eight low-voltage capacitors, sixteen high-voltage capacitors shown in Fig. 8, a standard transformer, a reactor and two enclosed spark-gaps. Both transformer and reactor were tapped to give the desired adjustments. Each of the low-voltage capacitors was 0.020-μf., 10,000-volt and each of the high-voltage capacitors was 0.008-μf., 16,000-volt. The reactor was designed for 14,000 volts and had 176 henrys maximum inductance. The spark-gaps were placed in parallel with capacitors *b c* and *b' c*.



Close-up of an experimental pole-top on taking 2½ kw. from a 66-kv. line

The individual capacitor unit is shown in Fig. 8. It is similar in design to those used for carrier current applications, but has a special rating. The construction is such that the capacitor will flash over the outside of the porcelain before it will flash through the inside; the characteristics are similar to those for line insulators; the wet flashover at 60 cycles is 70-kv. and the dry flashover is 116-kv. The weight of each capacitor is approximately 115 lb.

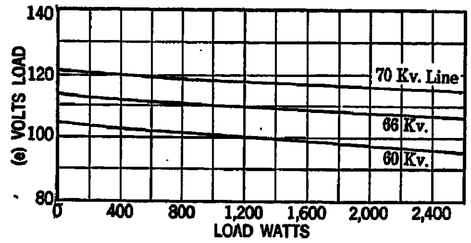


Fig. 5. Load-voltage curves taken from an experimental installation

INSTALLATION

The capacitap may be installed in several ways; by suspending from an existing tower, or from a tower or pole erected especially for carrying this load. The weight of the complete equipment shown in Fig. 4 is about 3000 lb. Although the equipment may be connected directly to the transmission line, the operating companies will probably use disconnecting switches. As this type of equipment may be mounted in suspension, it will be unnecessary to build an enclosing fence as required for equipment mounted on the ground.

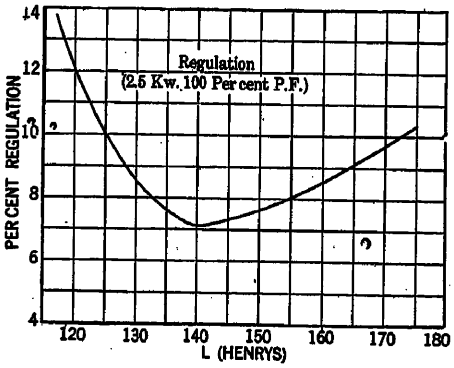

Fig. 6. Curve of regulation vs. inductance of reactor

A study of the various possible circuits has definitely shown that the capacitap may be well adapted to certain classes of loads, while for others the operation would be highly unsatisfactory. For example, either the supply of power to a beacon lamp load or the supply for charging a storage battery through a rectifier would be a satisfactory load; however, the operation of a large motor, or the closing of a circuit breaker would not be suitable. A current surge as encountered in starting a motor should not be delivered by the capacitor power supply as at present designed. Reference to Fig. 9 will show that as the load current increases, the voltage in various parts of the circuit rises, and in all places the maximum voltage must not exceed the rating for which each part is planned. The reactor used in the equipment built for study was designed for 14,000 volts; it will be seen, therefore, from curves of Fig. 9 that the load must not exceed 2700 watts. Also, an overload will cause a current which may saturate the reactor, a condition which would tend to limit the voltage rise on the capacitor. The spark-gaps were installed to protect the circuit from excessive voltage rises.

The capacitap and the transformer both supply low-voltage power from a high-voltage line and there are many things to be considered when choosing between them for any particular application. In general, where less than 3 kw. are required, the transformer will be better adapted to the lower-voltage systems, whereas the capacitap is better adapted to the higher-voltage systems. The dividing line between a high-voltage and a low-voltage system is rather indefinite and will depend somewhat upon the applications. For example, the supply of 2 kw. from a 44,000-volt line (25,400 volts to ground) will be best obtained from a transformer, while the supply of 100 watts at 110 volts for charging a storage battery (through a rectifier) may be economically obtained with the capacitap. For all ratings, the efficiency of the transformers and capacitaps is very high at full load, whereas a 50-kv-a. transformer (high voltage) used to supply 2 kw. will be much less efficient.

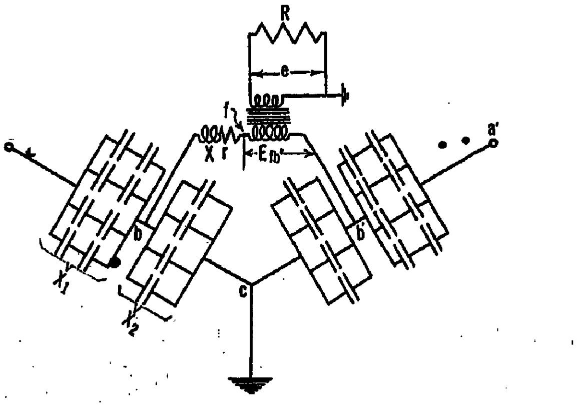

Fig. 7. Complete circuit of equipment shown in Fig. 4

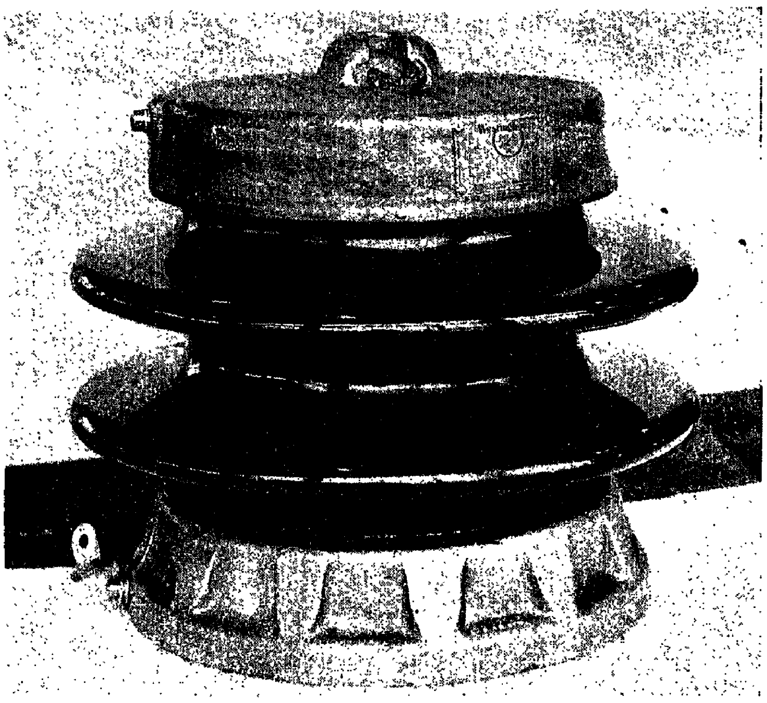

Fig. 8. Single suspension capacitor unit

There are so many variable factors in the design of a capacitap that all study has been limited to a grounded-neutral system; other arrangements adaptable to ungrounded or delta-connected systems will likely follow.

Single-phase power may be obtained from the use of a line-to-ground connection, (Fig. 2) or a double line-to-ground connection, (Fig. 7). Often one may be considered as a substitute for the other, although the inherent characteristics of each will greatly affect the choice. As will be shown later, the double line-to-ground circuit has a ground current which is constant and independent of load; however, the single line-to-ground circuit has a ground current which increases with load. If the ground current should become an important factor—especially in the vicinity of telephone circuits—it would be necessary to consider the use of the double line-to-ground circuit instead of the single line-to-ground circuit.

Another factor which should always be considered is voltage regulation; the nicer the regulation required, the larger and more expensive the equipment will become. The regulation is a function of the total kv-a. of capacitors and the ratio between the impedance of the line and ground branches of the circuit. The single line-to-ground circuit will be found to have slightly better regulation than the double line-to-ground circuit, using the same capacitors in either circuit.

The capacitor power supply (capacitap) is an assembly of capacitors and associated apparatus which supplies power at a reduced voltage from high-voltage lines. The present practical limit is from 3 to 5 kw. Tests have shown that such an equipment has characteristics which are suitable for certain types of loads only—such as airway beacons. The capacitors are very reliable, and being designed for suspension above the ground, with an enclosing fence unnecessary, the factor of safety is large. Two single-phase circuits are possible each having different characteristics with regard to ground current and voltage regulation. Only applications of the capacitap to grounded neutral systems have been considered; it is especially adapted to high-voltage systems.

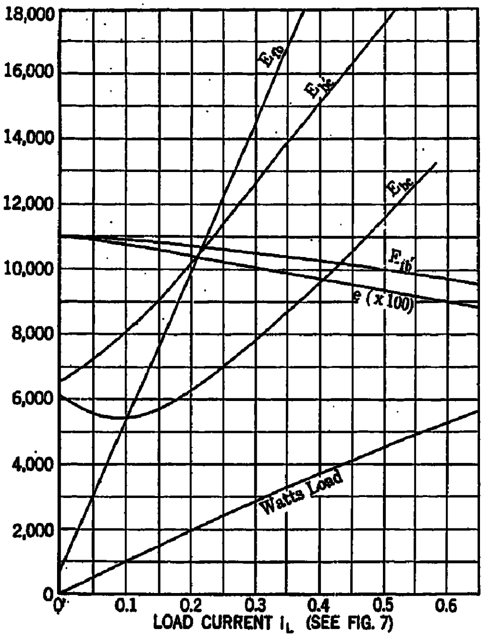

Fig. 9. Load and voltage characteristics

The condenser bushing potential device as developed by J. F. Peters supplied the basis for development of the capacitor power supply, and the author wishes to acknowledge with thanks, Mr. Peters cooperation in the present development.

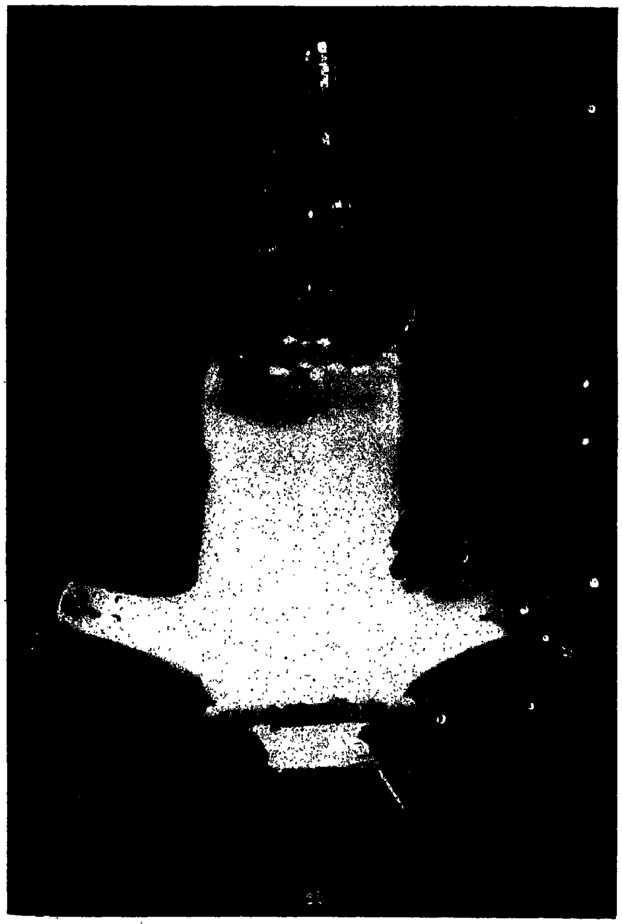
Vacuum Tubes Lead the Way

OF all the possibilities which beckon the scientist outside the narrow range of pressure and temperature in which we live, none has shown more alluring results than the family of vacuum or low-gas-pressure tubes. Incandescent lamps, X-rays, mercury rectifiers, radio tubes, photoelectric devices, and hyper-sensitive relays are among the substantial things which have already been summoned forth from the nothingness left by the vacuum pump. Other very practical developments are following; nowadays tangible results follow close upon the heels of theory.

A mercury grid-glow tube under development at the Westinghouse research laboratory, but not yet commercially available, can break 165 kw. (300 amperes, 550 volts) as often as desired, up to even a hundred times a second, with no burning of contacts. The control circuit of this contactor (for such it is in effect) takes so little current it cannot be measured.

This grid-controlled mercury switch is a lineal descendant of the little grid-glow tube which D. D. Knowles invented four years ago. It is in fact a grid-glow tube in which the cathode is a hot mercury pool. It looks like the mercury vapor rectifier to which it is akin; and like it, is started by tilting. The anode, however, at the top of the tube, is totally enclosed by fine nickel gauze (nickel, because it does not amalgamate with mercury). From this anode current flows to the mercury pool at the bottom, the two horizontal electrodes performing the "keep alive" function. A life of several thousand hours is expected. The efficiency is very high—about 99.9 per cent.

The importance of the device is more easily seen by viewing it not for its structure, as a sort of tube, but by its function, as a high-speed, arcless contactor, able to handle substantial amounts of current at any voltage up to several thousand with but a few micro-amperes in the control circuit—a contactor involving no wear of mechanical parts or maintenance, throughout its life.



A grid-glow tube that can interrupt 165 kw.

It already has been used to operate and control motors as large as 10 hp., and with an additional tube, was able also to serve for voltage control.

Some Aspects of

Federal Regulation of Water Power Development

Amazing advance in the use of electric energy during the past decade focuses attention upon the part played by the Federal Government in power development and production. Interesting facts are reviewed here.

By Frank E. Bonner

Executive Secretary
Federal Power Commission
Washington, D. C.

THE PREEMINENT position that has been attained by the United States in the utilization of electrical energy for turning the wheels of industry and lightening the labor burden of homes and farms, makes it of some interest to consider what assistance or encouragement the Government may have contributed toward this result. The primary relation of this industry is with the states, but with the growth of system interconnection, some problems of an interstate nature are beginning to arise. Proposals for their solution through imposition of Federal activity contemplate a minimum of interference with the existing machinery of the state agencies.

It is evident that the contacts of the Federal Government with the manufacturers and distributers of electrical energy have been confined mostly to those which are common to all industries. One prominent exception is in connection with the development of water power. Here through a combination of the Federal responsibility for navigation and the ownership of public land, the Government finds itself a shareholder in many potential water-power sites.

U. S. GOVERNMENT IS LARGEST REAL-ESTATE HOLDER

The fact sometimes is overlooked that the Government is by far the largest real-estate owner in the country. These holdings are concentrated chiefly in the Western states, where vast areas of the original public domain have been reserved for national forests, national parks, Indian reservations, and other purposes. There are also millions of acres comprising the unreserved public domain for which no use, sufficiently profitable, has yet been found.

Three-quarters of all the country's available water-power resources are found in the eleven westernmost states and, as might be expected, many of the potential sites involve United States land. Through the operation of the public land laws prior to the establishment of the policies under which water power and other lands were reserved, the Government's holdings have been reduced to scattered and fragmentary tracts which serve to give merely a minority interest in many important developments. The Government, however, with its sovereign powers may not be dispossessed through ordinary process of condemnation like other small land holders. Therefore, even though its stake in the ownership of numerous sites is small, it is in a position to dictate the terms upon which the entire development may be allowed to proceed. In the exercise of this unlimited authority the Government becomes an important factor relative to many Western projects which otherwise would be controlled solely by the state concerned.

FEDERAL JURISDICTION OVER STREAMS

The interests of navigation which supply the basis for the second element of Federal jurisdiction over certain water-power projects are derived from the fundamental law. The Constitution makes no reference to water power or navigation as such, but Section 8 of Article 1 embraces the following phrase:

> The Congress shall have power . . . to regulate commerce with foreign nations, and among the several States, and with the Indian Tribes.

By these few words the states surrendered to the central Government vast power under which many forms of Federal activity have grown up, including control of the waterways used or useful for the transportation of persons or property in interstate commerce. The definition of navigable waters subject to the control of Congress has been the subject of much controversy. Whether a stream is navigable or not seems to be a mixed question of law and fact.

While uncertainty will arise relative to the navigable status of individual streams, it is evident that many of the country's waterways are subject to Federal jurisdiction, and by the act of March 3, 1899, Congress decreed that "any obstruction not affirmatively authorized by Congress to the navigable capacity of any of the waters of the United States is hereby prohibited." This law has been construed to apply not only to all structures placed in waters actually navigable, but also to such obstructions on non-navigable tributaries which have the effect of substantially impairing the use of "navigable waters" lower down on the stream.

From the foregoing, it is apparent that even though the separate states possess the right to control the use and development of waters within their borders, the

---

From "Federal Relations to Water Power Development," presented at the Annual Meeting of the American Society of Mechanical Engineers, New York, Dec. 1-5, 1930.

National Government with its land ownerships and responsibility to navigation holds a basis for participation in the authorization of many water-power projects. Under existing law the administration of these interests is vested with the Federal Power Commission created in 1920. Prior to 1920 authorization for projects encroaching upon Government land or in navigable waters was obtained in various forms and from various agencies. These permits were of a revocable nature, and the difficulty of financing the cost of large works on leaseholds subject to bureaucratic vagaries led to a demand for legislation which would serve to promote the development of water resources.

FEDERAL WATER-POWER ACT

The Federal water-power act of 1920 is aimed to provide a uniform policy under which all of the permissive actions of the Government might be managed. It authorized the granting of licenses which are in the nature of limited leases for 50 years. Development by private capital or public agencies was encouraged to the fullest extent practicable by limiting hampering restrictions and administrative fees to a minimum. Moreover the licensee was assured a stable tenure by the guarantee of reimbursement for the cost or fair value of improvements in case the lease should not be renewed upon its termination. The law thoroughly recognizes the principle that the exercise of Federal jurisdiction should be subordinated to that performed by the states in their rightful fields.

In preference to setting up an entirely independent agency for carrying out the functions of the law, Congress chose to have the work continued by the technical staffs of the departments, composing the Commission of the heads of the three departments concerned. Pursuant to recommendation by the President, the last Congress authorized the substitution of full-time commissioners.

The law now has had ten years of trial, and it seems appropriate that inquiry be made concerning accomplishments and as to whether it is serving to encourage water-power development as intended. This decade has been characterized by enormous growth and expansion in the electric industry; consumption of electrical energy has increased 137 per cent, while the population has grown only 16 per cent. The rapidly expanding demand has created the need for huge new sources of production, and many noteworthy water-power plants have been constructed.

ACTIVITIES POWER COMMISSION

A substantial proportion of the new construction has been carried forward under the provisions of the Federal water-power act. Altogether the Commission has granted licenses for 449 projects. Only 107 of these are in the so-called major classification, larger than 100 hp., the others relate to minor projects and segments of transmission lines crossing Government land. Geographical distribution of the licensed projects shows great concentration in the Western states. California alone accounts for more than a third of the 449 projects, while the three Pacific Coast states together have just about half of the total number. Less than 10 per cent of the projects authorized are situated east of the Mississippi River.

Licenses of chief importance are those covering the 107 major projects, which range in magnitude from small plants constructed to serve isolated communities, to great public-utility developments. The giant generating stations at Niagara, at Conowingo, and on the Sierra Nevada streams of California furnish conspicuous examples of the large modern stations carried out under the existing Federal legislation.

Obviously, many of the proposed projects involve questions of a highly controversial nature, but in handling applications the Commission has moved with such diligence and dispatch that no complaint has been made that construction has been unduly delayed on any legitimate project or that essential interests of the public have not been adequately safeguarded. During the past year the Commission has granted licenses which authorize the installation of more than 1,000,000 hp. During the same period, 30 applications were rejected pursuant to the Commission's endeavors to prevent favorable sites from falling into the hands of speculative enterprises which are unprepared to proceed with construction.

PLANTS UNDER LICENSE

Aggregate capacity of completed plants operating under license amounts to about 2,600,000 hp. This comprises some 25 per cent of all the water-power capacity, and nearly six per cent of the total generating capacity in public-utility service. The Commission has no jurisdiction in respect to water-power developments other than the projects under license, and thus it is apparent that the scope of its authority in respect to the electrical industry as a whole is comparatively limited.

Contrary to popular impression, the Commission has almost no jurisdiction in the field of rate regulation. The law specifically limits the exercise of such functions by the Commission to those licensed projects not controlled by state regulation, and hence there has been little room for the Commission to engage in this function.

Since the authority of the Commission is by no means exclusive in respect to the licensed projects, the administration of the law has required close correlation with the activities of state agencies. In general, these relations have been entirely harmonious and mutually helpful, but at times there has been complaint that the Commission was stretching its authority unduly.

These complaints have related mostly to jurisdiction over projects located entirely on private land along non-navigable tributaries, where the Commission has assumed that the operation of the project works might serve to impair the use of navigable waterways lower down on the stream. The Commission's powers over such developments are rather vague and indefinite under the law, and a number of the states have challenged the Government's constitutional authority. They assert that the assumption of jurisdiction in such cases constitutes a serious invasion of the rights of the states, and interferes unnecessarily with developments of strictly local concern. For guidance in the matter the Commission has recently obtained an interpretation of the law from the Attorney General of the United States. This opinion holds that the Commission, in such cases, may grant licenses embodying terms restricted to those necessary for the protection of navigation. By thus harmonizing the respective jurisdictions of the State and Federal governments so that each may be effective in its proper field, a threatening shadow on the operation of the law will be removed.

Tests show conclusively that steam-electric generators may lose synchronism and pull back into step without giving any conclusive evidence of that fact either at the generator or in the control room.

IN THE PAST few years, the amount of analytical and test work on system disturbances and stability has increased tremendously, but very little of this theoretical or practical activity has dealt with the operation of steam-turbine governors. During 1929 a detailed investigation was made of the governor operation of the two 50,000-kw., single-cylinder, reheat-type turbines at the Stanton steam plant.

This plant is located near Pittston, Pa., and is jointly owned by the Scranton Electric Company and the Pennsylvania Power and Light Company. The steam connections and valves of the turbine are shown schematically in Fig. 1. All governing normally is done by the main control valve at the first stage of the turbine. Each generator has its own transformer bank and 66-kv. bus. Power normally is supplied by generator No. 1 to the Scranton Electric Company, and by generator No. 2 to the Pennsylvania Power and Light Company. The 66-kv. buses are tied together by a bus-tie reactor. Due to this reactor, generator No. 1 tends to swing with the Scranton Electric Company system and generator No. 2 with the Pennsylvania Power and Light system.

Some preliminary tests were made by dropping and picking up load on one of the turbines to be sure that the governor and all other equipment were functioning correctly under normal conditions of system operation; these tests did not indicate anything erratic in the operation.

Since short circuits were to be placed on one of the lines to the Scranton Electric Company from the 66-kv. bus supplied by generator No. 1, calculations were made to deterime the magnitude of the fault currents and the stability limits of the system under short-circuit conditions. Fig. 3 shows the results of these preliminary calculations, which indicated that the system would be stable with a one-conductor-to-ground short circuit, but unstable with a two-conductor-to-ground short circuit, when the generator was carrying full load. These calculations also showed that if the load on the generator was reduced to 25,000 kw. and the short circuit was cleared in less than ¾ sec. the system would be stable. The tests verified the calculations and are summarized in Table I.

Test No. 12, Fig. 4 shows the record of a two-conductor-to-ground short-circuit test. The output of generator No. 1 was reduced from 40,000 kw. to 22,000 kw. and the generator pulled out of synchronism with the rest of the system before the short circuit cleared, but generator No. 2, which was carrying a load of only

31,000 kw., did not pull out of synchronism. Generator No. 1 increased in speed until it tripped the emergency overspeed governor at 1,960 rev. per min., shutting off all steam input to the turbine. The turbine then drifted down to normal speed and pulled into step with the system 5½ sec. after the short circuit occurred.

A graphic voltage recorder with high-speed feature is normally used to record transient disturbances on this 66-kv. bus. The chart obtained from this instrument during this test is shown in Fig. 5. This chart should also be compared with the voltage chart shown in Fig. 6, which was taken during this test by means of a high-speed photographic recorder. This later type of instrument gives a true picture of the voltage conditions and the comparison illustrates the limitations of graphic instruments as recorders of fast transient phenomena.

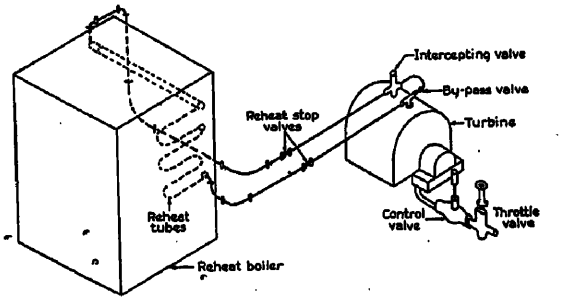

Fig. 1. Schematic diagram of piping and valves for turbines tested

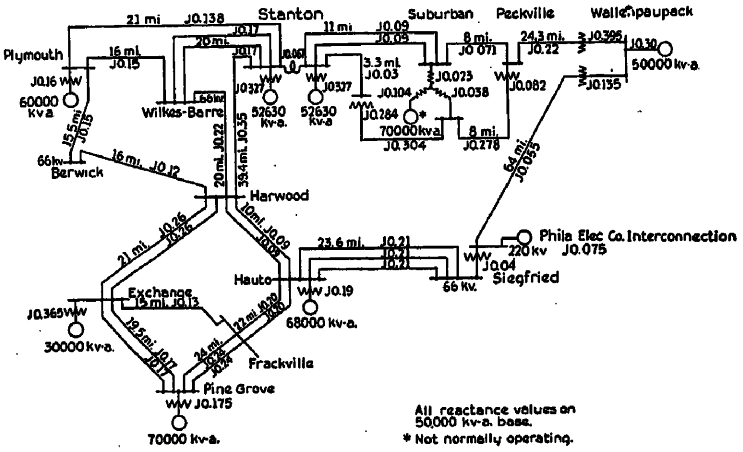
Test No. 23. Calculations had indicated that generator No. 1 would be stable with loads up to 25,000 kw., and a two-conductor-to-ground short circuit duration of less than ¾ sec. A two-conductor-to-ground short circuit was thrown on the system with a 25,000-kw. load on generator No. 1, but due to the relay setting which kept the short circuit on for 1.7 seconds, the generator again went out of synchronism, but did not trip the emergency overspeed governor. Generator No. 2 being heavily loaded (43,000 kw.) lost synchronism with the rest of the system and tripped the emergency overspeed governor. Violent oscillation of the governor beam of generator No. 1 occurred before it resynchronized. Fig. 7 shows the results of these tests.

The relay setting was changed to reduce the short-circuit time to 0.65 seconds and the short-circuit test was repeated. The generators did not lose synchronism, which shows the value of short switching time.

GOVERNOR PUMPING

Load Transfer Tests. Several operating companies have reported that during certain system disturbances the governor beams of the turbines have oscillated, and that this oscillation has continued for two or three minutes, or until some means was taken to correct the condition, such as holding the governor beam or disconnecting the turbine from the system. This phenomenon has been termed generally "governor pumping" and should not be confused with governor hunting which is a slow, periodic movement caused by lag of the valve behind the governor.



All reactance values on 50,000 kv-a. base.
* Not normally operating.

Fig. 2. Single-line diagram of interconnected systems involved in governor tests; only equivalent circuits shown for some parts

Load transfer tests were first made to determine if governor pumping could be produced by a disturbance of a minor magnitude but were unsuccessful.

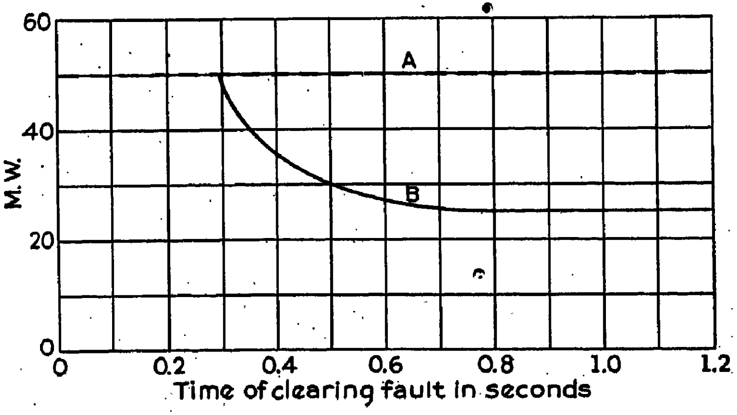


Fig. 3. Power capability of No. 1 generator plotted against switching time; (A) rated megawatts output, (B) output with two-conductor-to-ground fault outside generator transformer

Test No. 34. This was a two-conductor-to-ground short-circuit test in which the generator lost synchronism but did not trip the emergency overspeed governor, so that the speed governor still controlled the steam input. Reduction in the generator output due to the loss in synchronism, coupled with the normal speed-regulating characteristics of the governor, resulted in a sustained prime-mover speed above that of the system.

Fig. 8 shows the results of this test. During the first 2.5 seconds the movement of the main control valve was controlled by an auxiliary pilot valve which was being used in a preliminary form in an attempt to keep the turbine in synchronism; this pilot valve, however, had no effect on the governor or control valve after this initial period. Seven seconds after the short circuit occurred the governor mechanism started to oscillate at a period coinciding exactly with the kilowatt oscillation of the generator. The speed curve shown is a composite curve, composed of an average-speed curve obtained from the oscillograph record, and a superimposed speed change calculated from the output of the generator and added to the average-speed curve. From this composite curve it may be seen that if the governor follows the speed of the turbine it must alternately open and close the control valve an appreciable amount. The curves show that the governor was doing its best to follow these speed changes, although with about ¼ second time lag, and thus was varying the steam input in accordance with the speed, which is what a speed governor is designed to do.

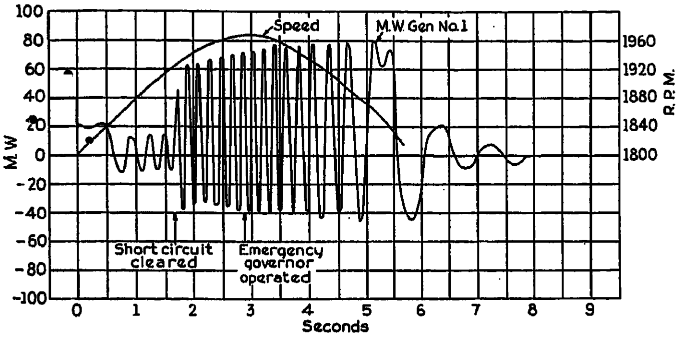

Fig. 4. Test 12. (Two-conductor-to-ground fault) shows No. 1 generator unstable, No. 2 stable

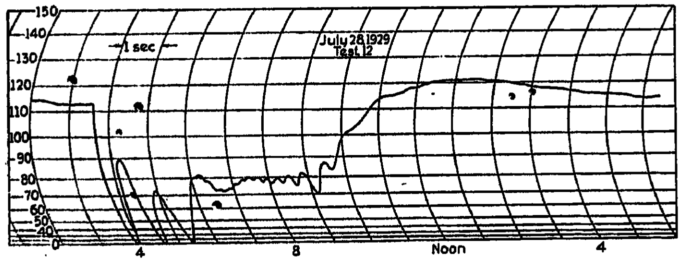

Fig. 5. Test 12. Graphic voltmeter chart from 66-kv.

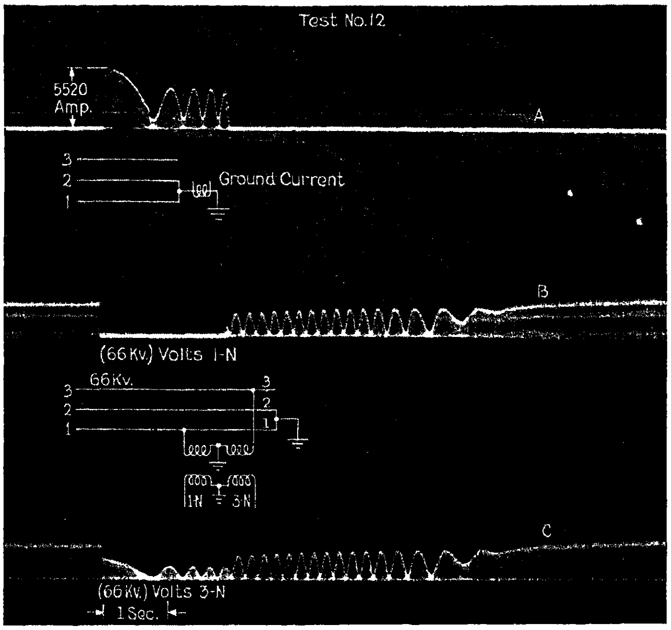

Fig. 6. Test 12. High-speed photographic record of ground current and voltage; (A) fault ground current, (B) voltage, phase 1-N, 66-kv. bus, (C) voltage, phase 3-N, 66-kv. bus

During the interval from the third to the seventh second, the periodic speed change caused by the generator slipping poles was so fast that it was impossible for the control valve to follow it. However, as soon as the average turbine speed came down to a point where the governor mechanism and control valve could follow the periodic changes in speed, the control valve started a pumping movement in which it assumed the proper position corresponding to the speed. This pumping of the governor beam was therefore a normal action and should be expected under conditions such as existed at the time of its occurrence.

Fig. 9 shows the speed-regulation curve for the governor of this turbine at the load carried when this test was made. If the turbine was completely unloaded it would run about five per cent above the normal system speed. The figure also includes a curve showing the relation between speed of the turbine and the induction-generator output of the generator for the voltage conditions which existed on this system during this test. The point where the induction-generator curve crosses the speed-regulation curve determines the speed of the turbine and the load which it will carry when it is out of synchronism. The average output of the generator during the period covered by the curves was about 13,000 kw. and the speed was about 3.3 per cent above normal.

TESTS WITH SPECIAL VALVE EQUIPMENT

In the previous short-circuit tests, all really severe system disturbances were accompanied by a loss of synchronism of one or both of the generators. The possibility of holding this turbine in synchronism by rapid reduction of input steam following a system disturbance seemed in this case to justify investigation. A special power-surge relay and a valve mechanism were designed therefore to shut off the steam input to the turbine by closing the main control and intercepting valves temporarily when a short circuit occurred. In order to obtain a fast reduction in steam input to the turbine it was necessary to operate both the control valve and the intercepting valve on the reheat loop.

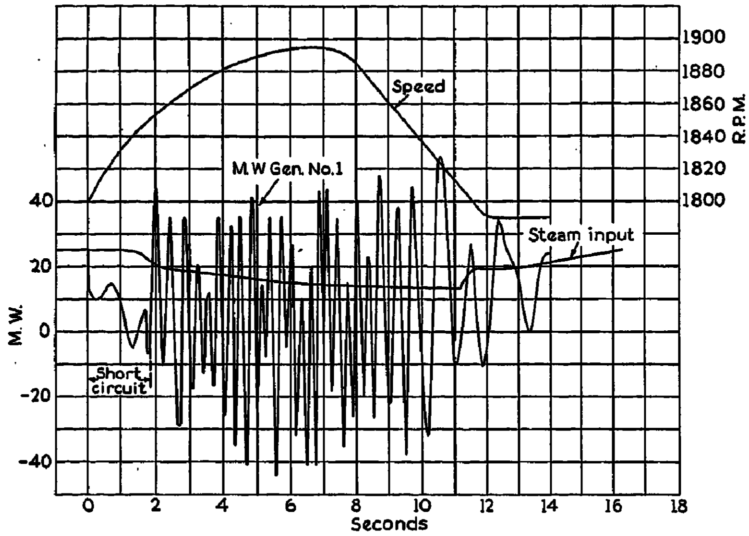

Fig. 7. Test 23. Both generators unstable and out of step with system and each other

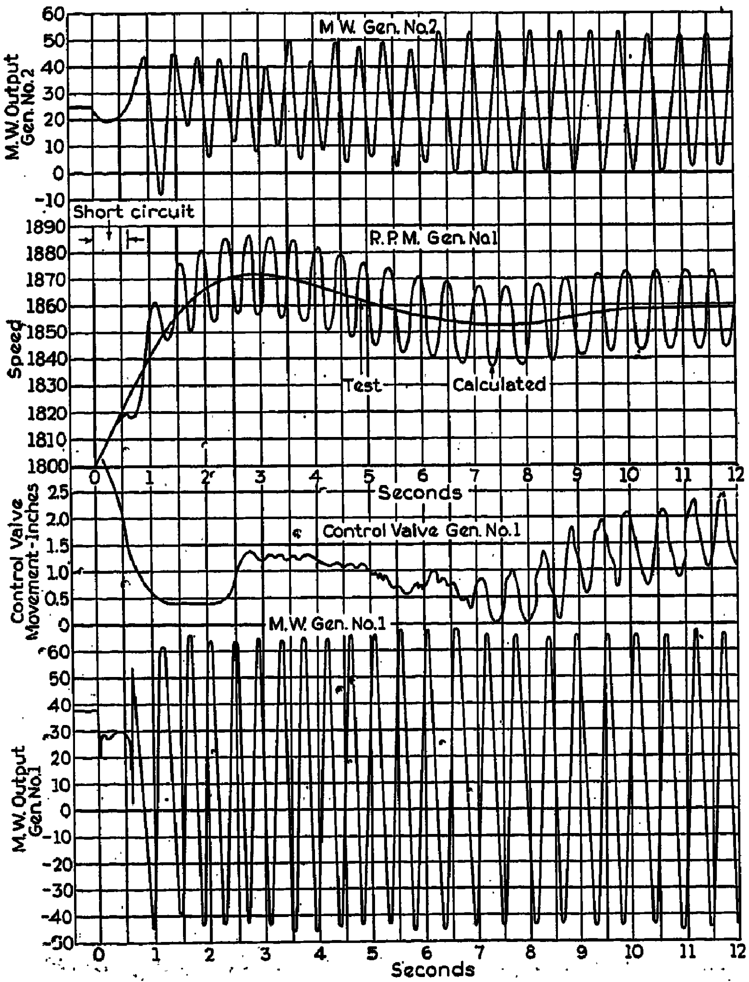

Fig. 8. Test 34. Governor and control-valve pumping

Test 51, Fig. 10 shows the results of a two-conductor-to-ground short circuit on the 66-kv. bus with the kilowatt load on generator No. 1 the same as for tests Nos. 14 and 23, and the short-circuit time the same as for test No. 23. The load on generator No. 2 was, however, somewhat reduced from its previous load. The steam input curve on this figure shows how the high-speed valve mechanisms used in this test, but not in tests Nos. 14 and 23, reduced the input so that the generator not only did not lose synchronism with the rest of the system, but even drifted back in angle so fast that it was taking power as a motor when the short circuit cleared.

Another test was made with full load on generator No. 1, and with the relay adjusted so that it cleared the short circuit in 1.78 sec. Generator No. 1 pulled out of synchronism with the rest of the system and, after slipping 16 poles, pulled back into step again. Although generator No. 1 pulled out of synchronism with the system during this test, it is believed that by a few further refinements in the relay and valve mechanism, it would be possible to keep this generator in synchronism with the rest of the system even for short circuits as severe as in this test.

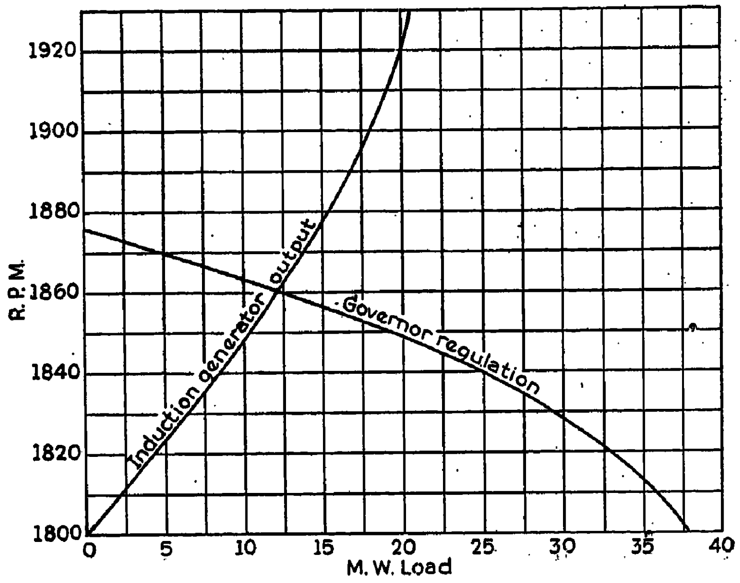

Fig. 9. Test 34. Turbine regulation and induction-generator power

These tests evidence the possibilities of this method for improving system stability and indicate results which are comparable with those obtained by the use of the more commonly proposed means for attaining the same end.

General Summary of Results

Results obtained shed additional light on some phenomena which have occurred during system disturbances and lead to the following general conclusions:

1. It is possible for a generator to lose synchronism and pull back in again without giving any conclusive evidence in the control room or at the turbine that such a change has occurred. Graphic charts and indicating instruments are not fast enough to indicate out-of-synchronism conditions reliably. Thus, this condition occurs far oftener than has been generally appreciated.

2. Cases of sustained system oscillation, or surging, seldom occur unless some generator, or group of generators, loses synchronism. Any oscillation resulting from a disturbance that is not sufficiently severe to cause loss of synchronism quickly dies out, due to the inherent system damping.

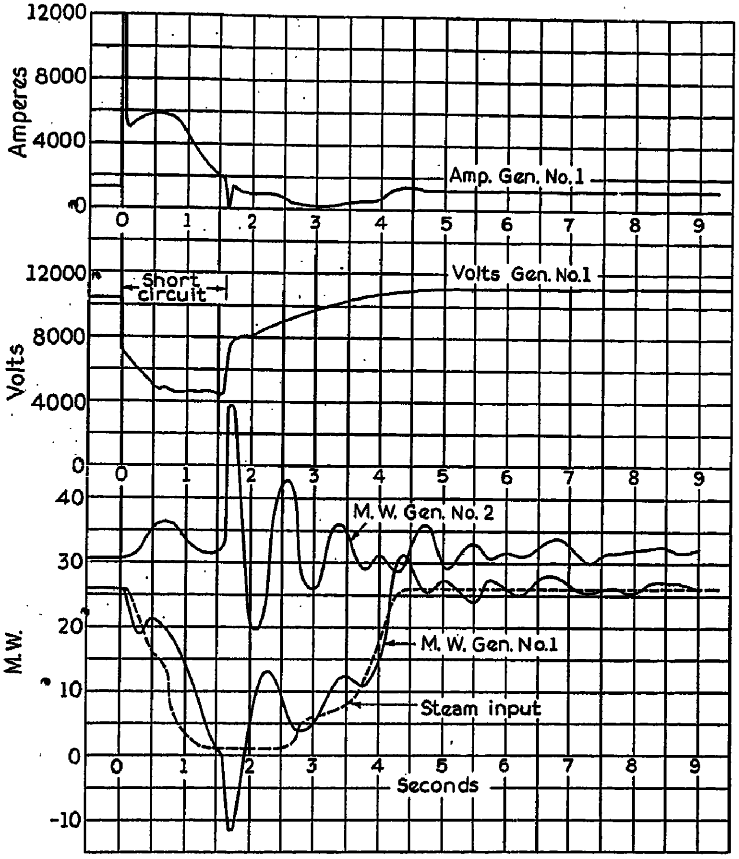

Fig. 10. Test 51. With special valve equipment both generators are stable

3. Governors properly designed and adjusted will not contribute to any system oscillation as long as synchronism is maintained. When out of synchronism, however, the governor attempts to follow the speed change as the generator slips poles, and the result is a "pumping" phenomenon familiar to many station operators. This pumping action is a result rather than a cause of a sustained oscillation and is to be expected when the generator and the system are out of step at a certain slip frequency. It will cease if the generator pulls back into synchronism.

4. When out of synchronism the speed of the turbine is determined by the regulation of the governor and the induction generator characteristics of the generator. The average output during this period may be an appreciable portion of the output before loss of synchronism.

5. In these tests the short circuits resulted in considerable reduction in the kilowatt output of the generators with consequent overspeeding and loss of synchronism. Special valve equipment for quick reduction of steam input following a sudden drop in generator output will increase the stability limits. Under certain conditions it may be of considerable benefit in maintaining stability, but under other conditions the equivalent improvement in stability may be better obtained by other means.

The authors wish to express their appreciation of the cooperation of Messrs. C. H. McKnight and J. E. Geue of the Stanton Operating Company in the performance of these tests and arrangement of system operation with connecting companies. They also wish to acknowledge the assistance of Mr. R. H. Park who initiated the tests with the high-speed valve mechanism, Mr. J. W. Dodge for assistance in the preparation of the test results and Mr. D. M. Jones for criticism of the paper.

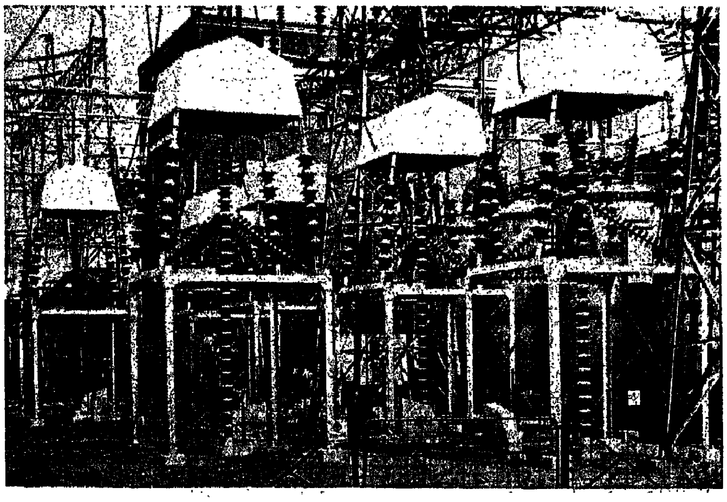
Lightning Arresters for 268.4-Kv. Service

THE highest-voltage lightning arresters ever built were recently installed by the Hydro-Electric Power Commission of Ontario. Under emergency conditions they will protect line voltages as high as 268,400 volts. This is also the largest arrester installation for voltages over 200,000. One three-phase arrester protects each of four banks of transformers on



These lightning arresters act automatically to protect against effects of waterwheel overspeed the 220,000-volt transmission line from Paugan to Leaside.

The disparity between the 268,400-volt rating of the arresters and the normal line voltage of 220,000 is a recognition of the inherent tendency of waterwheel generators, if the load is suddenly dropped, to overspeed, carrying the line voltage far above normal. Ordinarily, this situation has been met merely by using arresters rated high enough to withstand the maximum voltage without discharge. But this means that the line has less protection against lightning than were the arresters of only normal line voltage.

The Hydro-Electric arresters meet the situation by having a double rating, changing from one to the other automatically in emergency. Of the series of 22 auto-valve units in each phase leg, only 18 are necessary for 220,000-volt protection, and normally the other four are short-circuited by a high-speed automatic switch. When waterwheel overspeed and over-voltage occur, a relay opens this switch in less than half a second and cuts in the four remaining elements before the line voltage exceeds the limit of the 18 normally in circuit, thus providing protection at 268,400 volts.

An idea of the physical magnitudes involved in such voltages is gained from the fact that the gap sheds are large enough to accommodate an automobile. The arresters were built by the Canadian Westinghouse Company, Ltd.

Noise Measurements

That noises have a detrimental effect upon human health and happiness has been proved and now efforts are under way to control or eliminate objectionable sounds. Some of the problems involved are outlined and a newly developed "noise meter" is described.

By John C. Steinberg

Bell Telephone Laboratories, Inc.

THE INCREASING number during recent years of papers and editorials on city noise is evidence of a thriving interest in this aspect of modern life. People are questioning the necessity of this or that noise; makers of machines are looking for ways and means of attaining quieter operation; office and factory managers are asking about the effects of noise on the efficiency of employees; doctors and health officers are becoming interested in the effects of noise on the health of communities; and so on. Noise in this broad sense refers to any audible sound which is undesirable or which intrudes.

Within the past year there has been formed by Health Commissioner Wynne, the Noise Abatement Commission of New York City, and some 10,000 actual noise measurements have been made on the streets of New York. (A recent book, *City Noise*, by the commission, gives a comprehensive report of these measurements as well as other aspects of the noise abatement problem. This report may be secured from the Noise Abatement Commission, Department of Health, City of New York.) It is noteworthy that at one residential and two business locations the noise levels averaged over 15-min. intervals remained practically constant over a 24-hr. period, and the instant-to-instant levels for a 15-min. interval varied by as much as 30 or 40 db. Although these measurements were made at only three locations, they indicate that many residents of a large city are constantly immersed in a sea of noise, the average level at 3:00 a. m. being only a few decibels lower than the level during busy hours.

At this point it may be well to digress to the extent of making clear just what the term decibel really means. On the decibel scale, the unit is actually about equal to the smallest change which the ear can detect in the power level of a sound. Thus it is a ratio of intensity based upon the minimum audible unit; for instance, if the intensities of two sounds are in the ratio of 10:1, the sounds differ in level by 10 db.; if the ratio of intensities is 10^2:1 (100:1), the sounds differ by 20 db. In general, the number of decibels measuring the difference in level between two sounds is ten times the common logarithm of the intensity ratio, or power ratio.

It is a well established fact that constant exposure to noise takes its toll in the form of the extra energy needed to carry on the normal living processes with a consequent more rapid deterioration of the physical and nervous system. Experiments with typist and comptometer operators working under noisy and quiet conditions have shown that the effect of noise is to reduce the rate of accomplishment and to increase the rate of energy consumption by the body. (*Effect of Noise on Working Efficiency*, D. A. Laird, Loc. Cit. 1, and *The*

Based upon an oral presentation at the A. I. E. E. Middle Eastern District Meeting, Philadelphia, Oct. 13-15, 1930.

Effects of Noise, D. A. Laird, *Journal* Acoustical Society Jan. 1930.) Some of its physiological effects are an increase in brain pressure; a lessened regularity of the involuntary muscular changes of body organs such as heart rhythm, stomach rhythm, etc.; an increase in body movements during sleep; and probably in some cases a definite neurosis.

Since machines are the most common source of noise, the subject touches all fields of engineering. Such aspects of machinery as dependability, cost, safety, appearance, etc., have been the constant objects of engineering effort. Only recently, however, has the matter of noise emitted by machines begun to receive the serious attention of engineers.

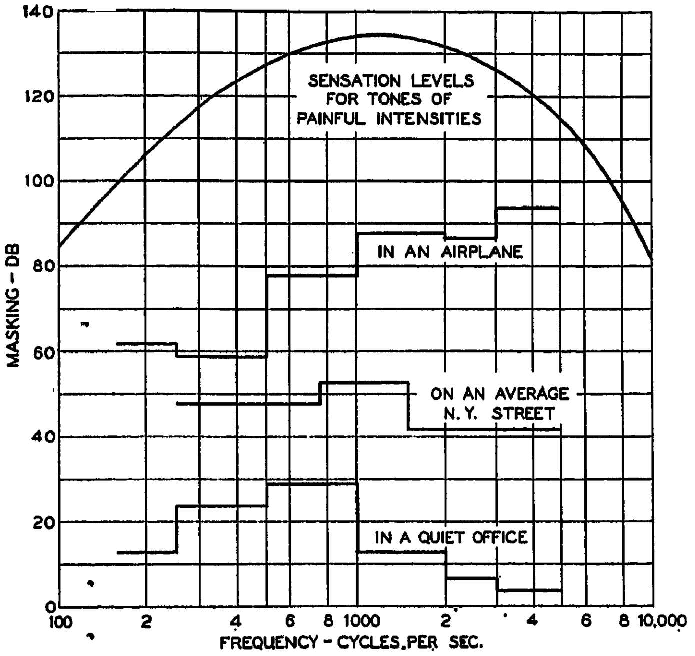

Fig. 1. An audibility chart showing how noises rob the human ear of an important part of its total range

Any study of noise naturally calls for a method of measuring and expressing the amount of noise. From a physical standpoint, this may be done in terms of the total sound energy and its distribution in frequency, and various methods have been devised and used to measure the physical energy of sound waves. For many purposes, however, it is desirable to express noise in terms that are more nearly related to the sensation caused by sound energy.

One method of doing this, called the audiometric method, is based on the fact that noise or the undesired sound masks other or desired sounds. ("Speech and Hearing," H. Fletcher, D. Van Nostrand Co., 1929, and "Auditory Masking," R. L. Wegel and C. E. Lane, *Phys. Rev.*, Feb. 1924.) If a certain intensity is necessary for a sound to be barely audible in a quiet place a greater intensity will be needed in the presence of noise. This shift in threshold is expressed in decibels; *i. e.*, ten times the common logarithm of the intensity ratio, and depends upon the intensity frequency spectrum of the noise.

If the masking caused by noise is observed with tones of different frequency, noise audiograms of the type shown in Fig. 1 are obtained. Two of these were with tones warbling through six different frequency ranges, and one with tones warbling through three different ranges. The curves illustrate three types of audiograms in which with increasing frequency the masking respectively increases, remains approximately constant, or decreases. As indicated above, the audiogram curves are "threshold-of-hearing" curves and the effect of noise is equivalent to a temporary hearing loss. In Fig. 1 the direction of increasing hearing loss is in the direction of the positive Y-axis, which is the opposite of the conventional way of plotting audiograms for the hard-of-hearing. (Loc. cit. (3) p. 199.) In the latter case, attention usually is focused on the hearing loss or upon how far the hearing is down from normal; in the former case, attention usually is focused on the amount that the intensity of a sound must be increased above normal to be audible in the presence of noise.

Useful hearing area in Fig. 1 is that below the curve for tones of painful intensities. The areas below the audiogram curves represent the parts of the useful area which are rendered useless by the noises. In order to be appreciated by the ear, sounds falling within these areas must be increased in intensity to a part of the area above the audiogram curves. For example, average speech as heard at a distance of from three to four feet from the speaker occupies the area between 60 and 70 db. Therefore, on an average New York street, it is only slightly above audibility; and in an airplane cabin becomes entirely inaudible.

The noise audiogram shows directly the loss in serviceable hearing caused by noise. For this reason it is very useful in many noise studies, particularly in the communication field and in the acoustic treatment of auditoriums, theaters, offices, etc., or where the chief concern is the perception of desired sounds in the presence of undesired sounds.

Amounts of noise may be expressed in terms of the sensation level and in terms of the loudness level of the noise. The sensation level is the ratio, expressed in decibels, of the noise intensity to the threshold intensity of the noise. If the intensity spectrum of the noise is known, the sensation level in most cases may be determined from the known minimum audible intensities of pure tones. The loudness level of a noise is usually expressed as the sensation level of some arbitrarily selected reference tone which sounds as loud as the noise.

Masking caused by a noise is measured by adjusting the intensity of a tone from a telephone receiver until it is just audible in the presence of the noise. The receiver is provided with a special offset cap which holds the receiver away from the ear by a small amount, so that noise may enter the ear simultaneously with the tone. The attenuator which is used to adjust the intensity of the tone is calibrated to read the masking in decibels. In one type of noise audiometer ("Methods and Apparatus for Measuring the Noise Audiogram," R. H. Galt, *Journal* Acoustical Society, Oct. 1929) a series of so-called "warbling" tones is used. These are tones which warble through a small frequency range, the range corresponding to each tone being located in a different part of the audible frequency range. Thus the masking caused by the noise is measured in different frequency ranges and when plotted against frequency gives curves of the type shown in Fig. 1. In another type of audiometer (Loc. Cit. 3) the masking is measured with a so-called "buzzer" tone, which consists of a fundamental frequency of 160 cycles and harmonic overtones, the overtones extending throughout a large part of the audible range.

The loudness level of noise is measured by adjusting the intensity of a reference tone until it sounds as loud as the noise. In this method, known to communication engineers as the balance method, the buzzer type of tone is used as a reference tone in some cases and in other cases, a 1,000-cycle pure tone is used.

In all of the above methods the ear is used in obtaining a judgment of the effects of noise. During the past two years considerable experimental work on devices to represent the effect of noise by the reading of an electrical meter has been done by various investigators of noise. (*A Survey of Room Noise in Telephone Locations*, Williams and McCurdy, A. I. E. E. Jour., Sept. 1930; "Practical Methods of Noise Measurement," by E. E. Free, *Journal* Acoustical Society, July 1930 "The Objective Measurement of Machinery Noise, by F. A. Firestone, *Journal* Acoustical Society, July 1930; "Results of Noise Surveys," R. H. Galt, *Journal* Acoustical Society, July 1930.) In all of these devices the noise energy is picked up by a microphone, suitably amplified and rectified and measured by a d-c. meter. The action of the devices is made to approach that of the ear by means of a "frequency-weighting" network. In some cases the weighting is based on the threshold intensities of pure tones; in other cases, on the intensities needed for pure tones to sound equally loud at some arbitrary loudness level. Although where the time characteristics and manner of integrating the components enter in such a procedure does not completely simulate the ear in its action to complex waves, it represents an advance over any method which neglects the ear entirely.

In most cases, noise meters of this type are calibrated to read the noise level in decibels from some arbitrary reference or zero value, such as the meter reading for a "just audible" tone or noise of a particular type. Noises having equal meter readings are approximately equally loud, the degree of approximation depending upon the similarity in energy frequency distribution of the noises being compared.

Noise meters of this type were used in both the N. Y. Noise Abatement Commission Survey of outdoor noise, and the survey of indoor noise by the joint subcommittee of the National Electric Light Association and the American Telephone and Telegraph Company. The frequency-weighting in these meters was based on the intensities needed for various pure tones to sound as loud as a 1,000-cycle tone having a sensation level of 30 db. Readings which would correspond to the threshold of audibility for a common type of noise were obtained for both meters by reproducing street noise phonographically at a known sensation level. Thus, measured noise levels could be expressed in decibels from the threshold settings. A graphical illustration of the noise level scale is given in Fig. 2 where the levels of

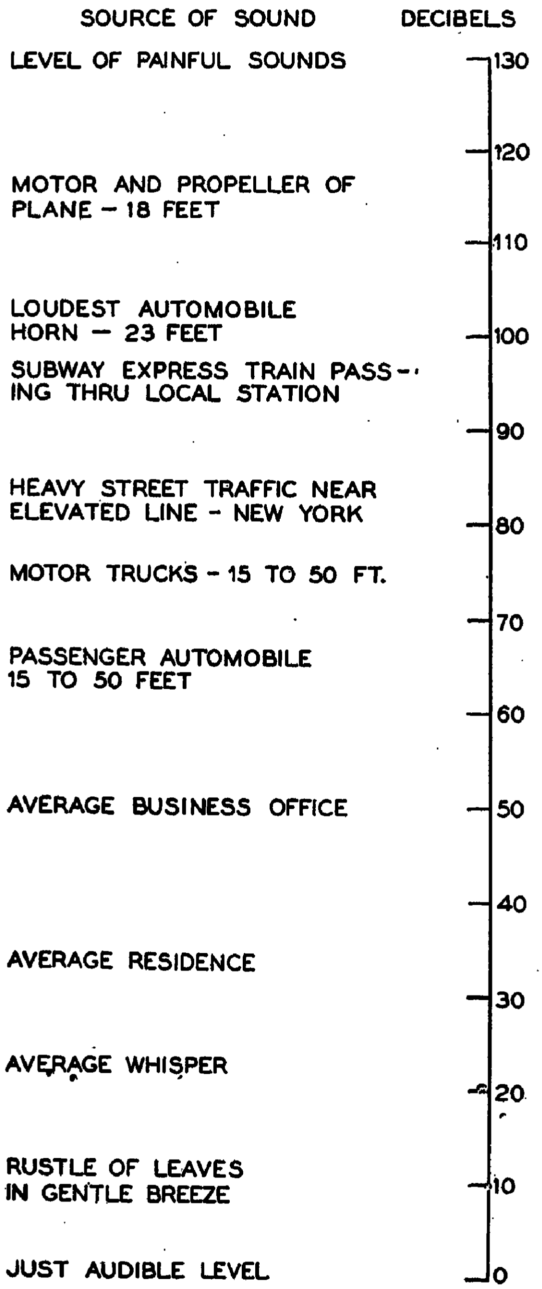

Fig. 2. A chart showing the decibel rating of some common sounds as compared to the "threshold of hearing"

some of the more familiar noises encountered in the surveys may be compared. The total range from threshold to painful sounds is 130 db. It may be seen that ordinary noises cover a large part of this range.

As previously indicated, noise meters such as that described are still in the experimental stage. In order to indicate loudness accurately for all types of sound waves, a meter must simulate the ear in at least three respects:

(a) In the relative sensitivity for sinusoidal waves of different frequencies.

(b) In the integration or summing up of the contributions of the component waves of steady complex sound waves.

(c) In the short-time average of fluctuating complex sound waves.

Further experimental work is needed in order to simulate the ear closely in all of these respects in a practicable noise meter and to determine the effects of various departures on practical noise measurement. The outstanding advantages of the objective type of measurement are that it reduces the personal equation and permits noise measurements to be made with great rapidity.

Private-Wire Telegraph Service

An important part of the entire communication service of the United States is devoted to private wire service. More than one and one-half million miles of private wire telegraph service is furnished to press associations, brokers, financial houses, public service companies, and other organizations and individuals. Some of the interesting features involved are described here.

By R. E. Pierce

Telephone Engineer
American Telephone & Telegraph Company,
New York
Associate A. I. E. E.

TELEGRAPHY has the distinction of being the earliest application of electricity in the service of mankind, and it still reigns as an important factor in commercial, educational and social activities. The commercial telegraph message business is essentially a point-to-point service and the telegraph facilities are designed and operated for the most part so as to furnish direct communication channels between two points. The private wire telegraph service, however, usually requires circuits with sending and receiving equipment at more than two points,—often at many points—and because of this fact the engineering problems involved are somewhat different from those in the commercial telegraph field.

Another unique feature of the private wire telegraph service is the fact that it is furnished very largely over plants which are used jointly for telephone and telegraph purposes. Thus if the private wire subscriber having printer service wishes to communicate with the attendants in charge of the maintenance of his service, he has merely to call on the telephone provided for the purpose, usually mounted adjacent to the printer installation. Immediately he is connected directly with the attendants at the printer service position in the nearest telegraph test room. In case of difficulty on the circuit, the telegraph attendant can communicate immediately with distant repeater attendants over test wires provided for the purpose, and with the monitoring printers, can make measurements over the private wire network in question. Transmission measuring apparatus and other testing means are also at his disposal.

The term "private wire telegraph service" as used in this paper covers that type of service by which a complete telegraph communication system is furnished to the patron for his exclusive use; this type of service is sometimes referred to as the "special contract" telegraph service. In that all facilities, including the station apparatus at the patron's premises, are furnished and maintained the service is complete. A circuit may be arranged for either the manual or machine method of operation to suit the requirements of the organization using the service, but since it is the term most universally used, throughout the paper the machine method will be referred to as the "printer method." Other terms in use by various organizations to describe the same method are "typing telegraph," "telephone typewriter," "teletype" and "teleprinter."

COMPARISON OF PRINTERS

The two systems of pointers in common use, the "multiples" and the "start-stop printer," differ in one important feature. In the multiplex system the signals

---

From "Modern Practises in Private Wire Telegraph Service," to be presented at the A. I. E. E. Winter Convention, New York, Jan. 26-30, 1931.

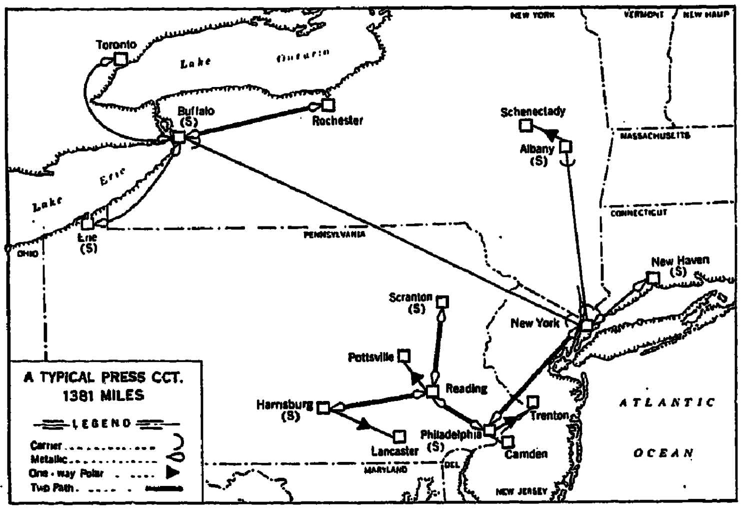

Fig. 1. Typical private press circuit involving 1,381 miles of line

are transmitted to the line and from the line to the receiving apparatus by distributing mechanisms which are operating continuously in approximate synchronism. In the start-stop system the signals are transmitted to the line and from the line to the receiving apparatus. These mechanisms start from a given position, transmit one character and then stop. In this latter arrangement the maintenance of synchronism between the sending and receiving devices is necessary only during the transmission of one letter or character. The multiplex system is essentially a point-to-point system, whereas the start-stop system is adapted to circuits involving a large number of stations, any one of which may send or receive. The advantage of the continuously synchronized system of transmission is the possibility of using a shorter code; it is necessary to transmit only the intelligence-bearing signals, whereas in the start-stop system a signal is sent to start, and another to stop the distant distributor mechanism.

The fundamental advantage of start-stop over continuously synchronized systems is the fact that in the start-stop system the lag in the transmission of a signal from one point to another point in a circuit is automatically taken into account. With only two stations on a given circuit an initial adjustment can be made to properly orient the receiving device with respect to the sending device which will hold as long as the lag remains fixed. With more than two points in a circuit—any one of which may send to all the others—or with transmission systems which are apt to be changed in a way that affects the lag, the adjustment to compensate for lag becomes difficult if not impracticable. This feature would restrict considerably the field of use for continuous synchronism in private wire telegraph service, where such a large portion of the circuit requires service between more than two points, and where it is essential to maintain a flexible plant in order to maintain continuous service. This explanation will indicate why the multiplex system, designed as a continuously synchronized system, is used in the commercial telegraph message service while the start-stop system is used in the private wire telegraph service.

SELECTIVE DIAL CALLING

For services where it is desirable to select particular stations yet impracticable to provide a switchboard with individual circuits to each station, a selective calling arrangement has been developed. With this plan all stations are connected to the same circuit and selective signals are transmitted from one station to another over the circuit used for passing the telegraph signals. The apparatus used to accomplish this consists of telephone dials, step-by-step switches, and relays. Any point on the circuit may be called by dialing any other point on the circuit. A station may also dial by a single three-digit code all other stations or a group of stations. When the circuit is in use, "Busy" signals appear at all stations, and an audible or visible alarm is provided to call the attention of the attendant to an incoming message. When the station is idle the motors of all printers are stopped but start automatically when the station is called and stop automatically when a call releases the circuit. Secrecy is obtained in the system through the fact that it is impossible for a station which has not been called to "listen in" on a circuit in use.

INDUSTRIAL APPLICATIONS

The foregoing gives briefly the general principles of the systems of private wire telegraph service in general use in this country. The following describes special application of private wire systems to various industrial systems:

Press Service. Private wire telegraph service is the means used by the press association for accomplishing quickly, accurately, and without interruption, the collection and distribution of news. A typical telegraph network—one of the many circuits of one of the leading

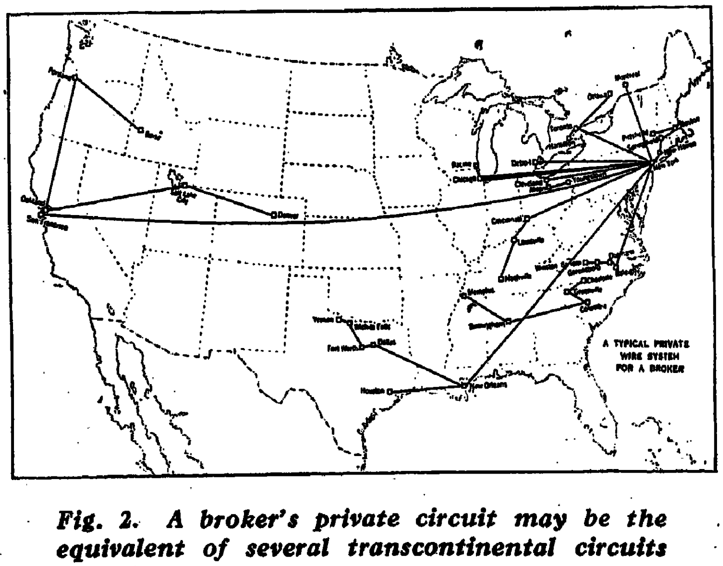

Fig. 2. A broker's private circuit may be the equivalent of several transcontinental circuits

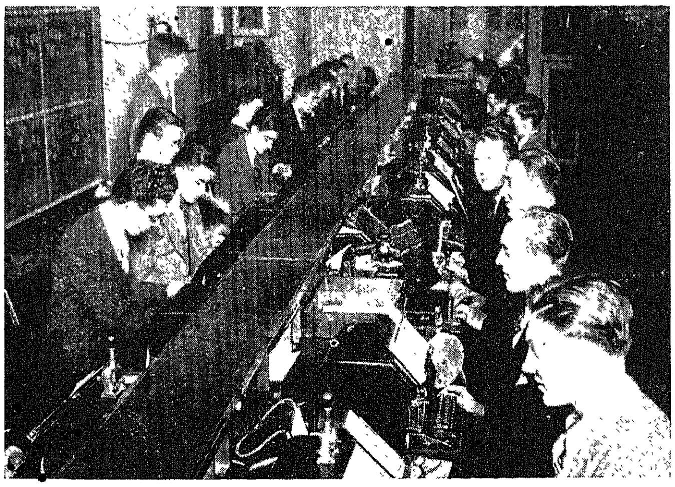

Fig. 3. A broker's private wire room is a busy place

press associations in the United States—is illustrated in Fig. 1. It will be noted that this network contains approximately 1,400 mi. of telegraph circuits and connects sixteen telegraph stations, five of which are arranged for both sending and receiving while eleven are for receiving only. The various types of telegraph systems involved in this particular service are indicated by the designations on the chart.

In a service of this kind most of the sending would be done from New York; it will be noted, however, that there are other points on the network indicated as sending stations. The circuit must be arranged with "break" feature so that when desired, any one of these other sending stations may take control of the entire network and transmit to all stations. To accomplish this the operator at the station transmitting the message operates the break key on his machine which transmits a break signal over the circuit, locking up the machine which has been sending and thereby indicating to the operator at that point that another station wishes to send.

In most cases the printers involved in the press work are of the page type, using a continuous roll of paper. The sending machines are usually equipped for what is known as automatic transmission; the sending operator manipulates a keyboard which controls a perforator. This perforator prepares the message to be transmitted in the form of a perforated tape to be fed into a transmitter connected to the line. The transmitter is operated at a speed for which all the printers on the line are set; the perforator may be operated at any speed desired. If the speed of the line is exceeded by the perforator (as is usually the case) the message is stored up in the tape and is transmitted to the line at a regular rate. With this method of transmission there is a continual flow of traffic over the line and any interruption in the operation of the keyboard does not interrupt the signals going to the line. This arrangement obtains the maximum efficiency from the line.

In certain cases a "bulletin" or "flash" of special importance must be transmitted; arrangements are provided so that by throwing a key the transmission of signals from the perforated tape is stopped and the keyboard is connected directly to the line so that as each key is depressed the proper signals are transmitted. In this way the "bulletin" or "flash" may be sent without delay directly to the line from the keyboard, and when it is complete, the regular flow of traffic may be resumed by restoring the key mentioned previously. In order to attract the attention of the operators at the newspaper offices to such a flash or bulletin, a bell is provided on the printers and caused to ring by the transmission of a particular combination of impulses from the sending keyboard.

Brokers' Service. A large percentage of the business involved in the trading on the stock and commodity exchanges is handled over the private wire systems of the various brokerage concerns. Fig. 2 shows a typical broker's service which comprises several separate circuits. This service is operated by the printer method, and Fig. 3 is a view in one of the wire rooms of this brokerage house. In the brokerage houses the wire network is used for passing information regarding orders placed before the market opens, and for distributing certain market letters or market "gossip." When the market, opens, the wires are kept busy with the passing of orders, confirmations, and questions and answers concerning specific securities. From the illustration it will be noted that the tape printer is used and the cover of the machine cut away in such a fashion as to allow the tape to be removed from the machine immediately after the last character of an order is printed. The orders are gummed on "buy" or "sell" order blanks and are then handled in the usual way. In the afternoon after the market closes the wires, in cleaning up the day's business, continue to handle a large volume of traffic; the records are checked and verified and all matters cleared before the opening of business on the following day. It is reported that during four days of

Fig. 4. Telegraph printer systems are expediting and amplifying effective police work

the record month of October 1929, one of the brokers using this service handled the remarkable total of 49,860 orders, confirmations, and general messages over the firm's six private wire telegraph circuits.

Police Systems. Various police organizations throughout the country are finding the private wire telegraph service a reliable means of quickly disseminating police information. These police systems are essentially broadcasting networks for transmitting police information simultaneously to a large number of receiving stations from one or more central points. The information usually originates in a telephone call or a personal visit to a police station from which the information can be quickly transmitted to the central headquarters and from there sent out on the broadcasting network. Regardless of whether or not the station is attended the receiving machines make a record of the message. In certain cases the receiving machines are equipped with an audible alarm so that a police officer at a distance may be advised that a message is being received. In certain cases it is desirable to provide arrangements whereby the broadcast headquarters will know whether the message is received at each point to which it was transmitted; then an acknowledgment signal is arranged so that after each message is transmitted, the ringing of a bell on the receiving printer indicates that the transmitting station requests an acknowledgment. This can be sent back by pushing a button on the receiving machine, the acknowledgment lighting a lamp on the switchboard at headquarters.

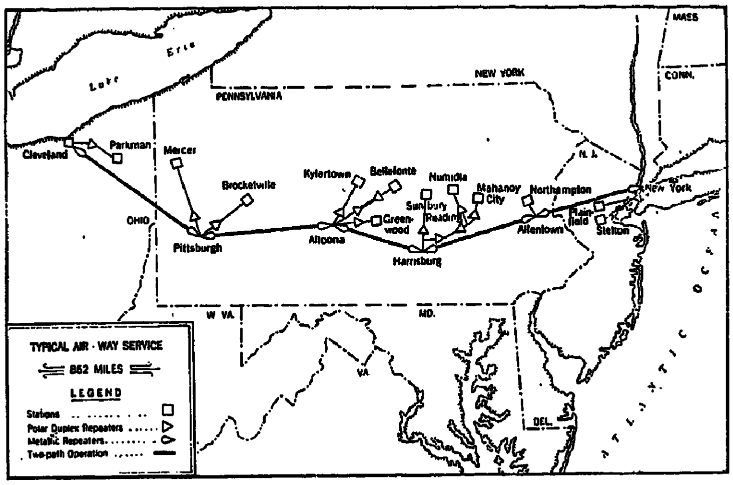

Fig. 5. Communication with planes in flight is becoming of greater importance; this is a typical private airway circuit

Other police networks are set up with all stations connected to the same circuit so that any one may send, and all of the others receive. Such a circuit connects fifteen of the principal municipalities in Connecticut, and in this way police information originating in any of these towns can be broadcast simultaneously to all of the other towns on the network.

Fig. 4 shows one of the switchboards and sending machine in a state police system.

Weather Reporting Systems for Airways. The Department of Commerce has contracted for quite a large network of private wire telegraph circuits for use in collecting and distributing weather information for use by aeroplane pilots. Weather information is collected on an hourly basis in sequence from the principal intermediate landing fields and critical points along an air route. It takes from four to five minutes to make such a weather collection over a typical air route between major landing fields. The weather information thus obtained is furnished to the air pilots before they leave the field or to pilots in the air by means of the radio telephone equipment of the Department of Commerce. Along the air route the printers are usually installed adjacent to the field in what is known as a watch-house. In addition to the service mentioned, in certain local cases private wire circuits are provided for the purpose of distributing weather information between the Weather Bureau, radio stations, airports and air transport companies' offices.

In addition to the collection of weather information the private wire circuit is used in some cases for reporting the departure, arrival, and passing of planes. Fig. 5 shows a typical airway network. The stations along the air route are usually connected in series so that each station receives the information sent from all other stations. In some cases the bell signal on the printer is used to call the attention of a particular station with which it is desired to communicate.

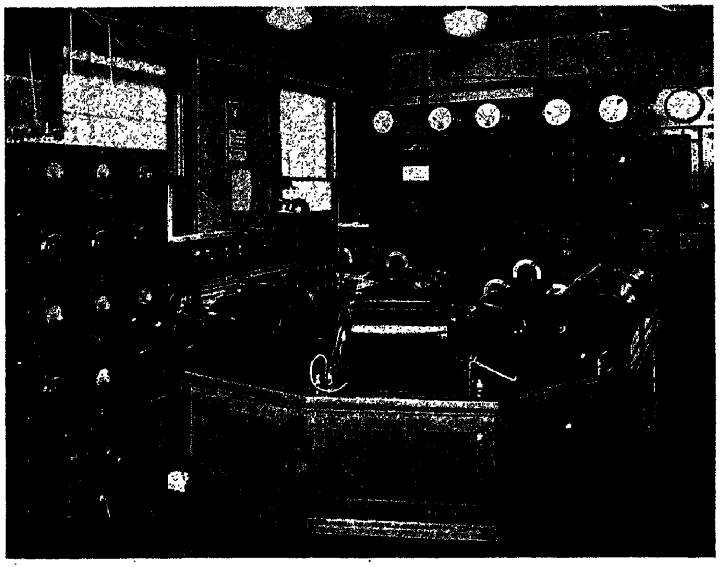

Fig. 6. A modern airway communication office

Manufacturing Service. Factories are generally located with regard to the availability of raw materials and the ease of transportation; executive and sales offices, on the other hand, are usually near the distributor, the exporter or the consumer. Private wire telegraph service is used extensively to provide direct-communication channels between the widely separated units of modern industrial organizations. With the aid of this service the far-flung units of this organization are kept in constant touch with each other, thereby speeding up production and improving the service rendered to their customers.

In looking forward to the future, there seems to be every indication that private wire telegraph service will continue to grow and expand, and with the requirements continually changing it is to be expected that many new and interesting developments will be applied to this service.

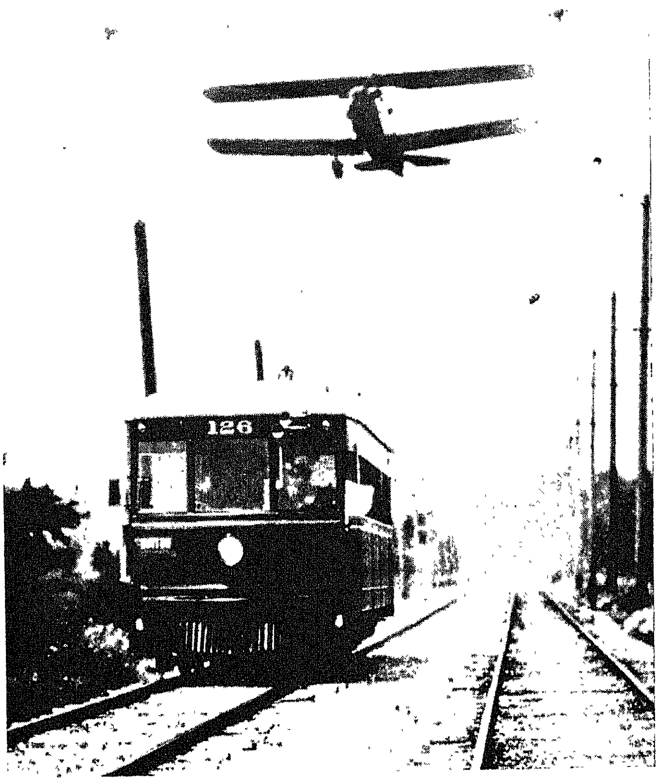
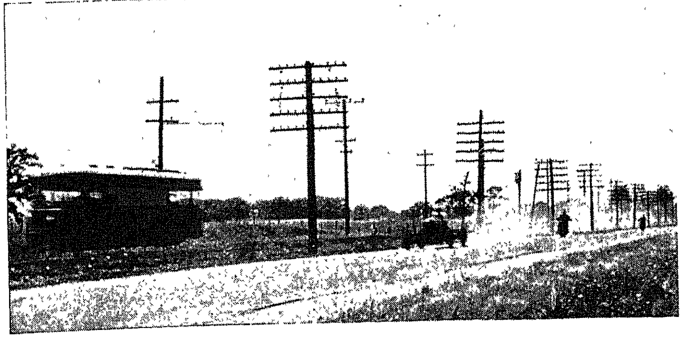
Ninety Miles an Hour in a Trolley Car!



Outwitting the "speed cops"; electric car traveling at more than 90 mi. per hr.

THE fastest interurban cars in the world are leaving competing buses nearly an hour behind on the 225-mile run between Cincinnati and Toledo, though the bus route is shorter by 15 mi. By their owner, the Cincinnati and Lake Erie, these cars have been clocked at 90 mi. per hr. or better. During trials, police motorcycles were left behind, and even the aeroplane scarcely overhauled the "flying" trolley.

Unlike previous extremely fast cars, these are neither very large nor heavy. They weigh but 24 tons, seat 40 people, and are of one-man operation. Their motors rate 100 hp. each, (quadruple equipment) and in the case of the ten Westinghouse equipments, weigh complete but 2,690 lb. How extraordinarily light this is, is shown by contrast with other motors bought by this road in 1927 which weighed half again as much per horsepower. The remarkable lightness of the new motor is partly due to improved insulation, but largely to the high rotative speeds found practicable through its being wound for 300 volts. The principal advantage of the lower voltage, however, is the marked benefit to commutation. The motors are geared 26:46 on 28-in. wheels.



Only an airplane succeeded in overhauling this new interurban electric car

In general, the experience of the Cincinnati and Lake Erie does not show that high speed offers any particular difficulties. The permanent way was put in first-class condition, with especial attention to the safe elevation of curves and the alinement of overhead, but no departure from normal standards was needed.

The interurban roads have had more than their share of post-war difficulties, but the Cincinnati and Lake Erie and its chairman, Doctor Thomas Conway, have produced substantial proof of the rewards that the industry still offers to courage and to vision.

Aeroplanes, automobiles, and yachts race for amusement, but trolley cars do not; they race strictly for revenue. So it is important to observe that in the second month of the new cars, passenger ticket receipts in three of the principal cities had increased 77 per cent. Over Labor Day, 17 of the trains had to be run in two or more sections, and in November it was understood that the cars were, as show people say, "packing them in"—and this on a road which a year ago was not embarrassed by density of traffic any more than is the average interurban road—on a road paralleled by good highways over a shorter route, by first-class buses, and by fast steam trains.

Winter Convention Presents Attractive Program

Engineering Papers, Inspection Trips, and Entertainment of Striking Interest Assure Busy, Profitable Week

MANY excellent developments in various fields of electrical engineering will be brought out in the technical sessions at the A. I. E. E. winter convention. This meeting, which promises to equal in interest any of the past winter conventions, will be held in New York, January 26-30, with headquarters in the Engineering Societies Building. In addition to the excellent technical program there will be a number of interesting trips and good entertainment with a specially arranged program for the ladies.

Technical Sessions

One of the sessions that should prove of general interest is the symposium on coordination between power and communication circuits. The papers which are to be presented represent the work of a joint general committee of the National Electric Light Association and the Bell Telephone System. Each paper was prepared by a representative in the power field and a representative in the communication field jointly. The achievements obtained are a noteworthy example of cooperation between different fields of the electrical profession.

At the opening of the session R. F. Pack, vice-president and general manager of the Northern States Power Company, will make an introductory statement. Following the presentation of the papers closing remarks will be made by Bancroft Gherardi, vice-president and chief engineer of the American Telephone and Telegraph Company. The session should have a broad general appeal and the papers to be presented are not highly technical or mathematical.

Many recent developments involving design, theory, operation, and testing will be brought out in the papers which will be presented in nine other sessions in the fields of telegraphy, transportation, protective devices, power transmission, industrial power applications, electric welding, electrical machinery, and research.

Edison Medal Presentation

The Edison Medal will be presented to Doctor Frank Conrad for his contributions to radio broadcasting and short-wave radio transmission. Presentation will take place in the Engineering Auditorium on the evening of Wednesday, January 28.

Following the presentation ceremonies a lecture will be delivered by Doctor Karl Taylor Compton, president of Massachusetts Institute of Technology.

Smoker

A buffet dinner and smoker will be held in the Engineering Societies Building on Tuesday evening, January 27. This informal occasion affords a splendid opportunity for members and their guests to renew old acquaintances. Plans are being made which will provide very attractive entertainment after the dinner, to be served by Louis Sherry.

Dinner Dance

The dinner dance of the winter convention will be held in the Grand Ballroom of the Hotel Astor on the evening of Thursday, January 29. For many years this annual social event of the Institute has afforded much pleasure to all in attendance and is looked forward to from year to year by a large proportion of the membership. Tickets will be $6 per person. Reservations may be made in advance for tables seating eight people.

LADIES ENTERTAINMENT

The ladies entertainment committee is actively engaged preparing a special program which will prove very attractive for the ladies in attendance.

PROGRAM OUTLINE

MONDAY, JANUARY 26

10:00 a. m.	Registration
2:00 p. m.	Opening of Convention A—Symposium on Telegraphy
8:15 p. m.	B—Joint Session of Committee on Transportation and the Transportation Group of the New York Section

TUESDAY, JANUARY 27

10:00 a. m.	C—Symposium on Coordination of Power and Communication Circuits
2:00 p. m.	D—Session on Protective Devices
6:00 p. m	Buffet Dinner and Smoker

WEDNESDAY, JANUARY 28

10:00 a. m.	E—Session on Power Transmission
2:00 p. m.	Inspection Trips Board of Director's Meeting
8:30 p. m.	Edison Medal Presentation and Lecture

THURSDAY, JANUARY 29

10:00 a. m.	F—Industrial Power Applications
2:00 p. m.	Technical Sessions G and H G—Transportation H—Electric Welding
7:30 p. m.	Dinner Dance

FRIDAY, JANUARY 30

10:00 a. m.	I—Session on Research
2:00 p. m.	J—Session on Electrical Machinery

TRIPS

On the inspection trips offered many prominent developments of interest to the electrical engineering profession may be seen:

1. The Hudson River Bridge with construction work now in progress offers an unusual opportunity for engineers to view a remarkable feat in bridge construction. The main span, 3,500 ft. in length, is the longest single span in the world and is supported between towers which rise to a height of 635 ft. above the water's surface. Four cables each made up of 26,474 wires giving a specified minimum strength of 220,000 lb. per sq. in. and weighing 28,450 tons, support the double-deck structure. Construction work was started in May, 1927, and the initial portion consisting of four traffic lanes and two sidewalks is scheduled to be opened to traffic early in 1931. The ultimate plan provides for eight traffic lanes and two sidewalks on the upper deck with a lower deck to accommodate four rapid transit tracks. The cost of completion of the initial stage of the construction is estimated to be $60,000,000.

2. Vertical distribution in modern skyscrapers such as the Chrysler Building and the Empire State Building. The Empire State is the tallest building in the world.

3. New Eighth Avenue Subway Substations

4. Tandem-compound, 160,000-kv-a., steam-electric generating unit of the New York Edison Company.

5. Modern press installation and lighting of the new Daily News Building.

6. Modern use of light as the sole decorative agent in a large ballroom—St. George Hotel, Brooklyn, N. Y.

7. Railroad electrification as exemplified in the newly completed properties of the Delaware, Lackawanna & Western Railroad.

8. The Westinghouse Lighting Institute.

9. New York Museum of Science and Industry.

10. Roseland switching station of the Public Service Electric and Gas Company (New Jersey).

Details as to transportation tickets, etc., will be announced in the programs distributed at the convention.

REDUCED RAILROAD RATES

Under the certificate plan reduced railroad rates will be available to members and guests who attend the convention; only half fare need be paid on a return trip over the same route, provided a total of at least 150 certificates are deposited at the registration desk. Rates apply to all who attend the convention and to dependent members of their families. Each member or guest should obtain a certificate when purchasing his one-way ticket to New York, explaining to the ticket agent that he wishes the certificate authorized by the passenger associations for the winter convention of the American Institute of Electrical Engineers.

On arriving at the convention the certificate should be deposited at the registration desk. There it will be held for validation by a railroad representative and if 150 or more certificates are validated, these certificates will be returned to the owners. By presenting the validated certificate when purchasing a return ticket, only half fare will be charged. Local ticket agents should be consulted regarding conditions affecting this plan, as it applies only within certain dates, depending upon the territory. *Everyone* whose one-way fare is more than 66 cents *should get a certificate* whether or not he intends to use it. *By neglecting to do so others may be deprived of considerable saving.*

REGISTER IN ADVANCE

Each member should register in advance by mail, thus permitting the committee in charge to have the badges ready, resulting in a considerable saving of time and congestion at the registration desk.

COMMITTEES

The 1931 winter convention committee is constituted as follows: H. P. Charlesworth, Chairman; J. B. Bassett, C. R. Jones, H. A. Kidder, G. L. Knight, A. E. Knowlton, E. B. Meyer, C. E. Stephens and R. H. Tapscott.

Chairmen of subcommittees are, respectively: J. B. Bassett, convention executive committee; W. R. Smith, inspection trips; E. J. Johnson, dinner dance; G. W. E. Draper, smoker; and Mrs. E. B. Meyer, ladies entertainment.

HOTEL RESERVATIONS

Reservations for hotel accommodations should be made by writing directly to one of the hotels listed in the mailed announcement of this convention.

Newly electrified section of Lackawanna suburban lines serving New York City

Technical Program

January 26—2:00 p. m.

Opening of Convention

Remarks by President William S. Lee.

Statement by A. E. Knowlton, chairman, meetings and papers committee.

A—Symposium on Telegraphy

Presiding officer: H. S. Osborne, vice-chairman, of the committee on communication.

The Newfoundland-Azores High-Speed Duplex Cable, by J. W. Milnor, C. H. Cramer, W. D. Cannon, and J. A. Randall, Western Union Telegraph Company.

Submarine Cable Telegraphy; Influence of Interference, by J. W. Milnor, Western Union Telegraph Company.

Telegraph Transmission Testing Machines, by F. B. Bramhall, Western Union Telegraph Company.

A Printing Telegraph Concentrator, by W. B. Blanton, Western Union Telegraph Company.

Modern Practises in Private Wire Telegraph Service, by R. E. Pierce, American Telephone and Telegraph Company.

January 26—8:15 p. m.

B—Joint Session on Transportation

The New York Section's Transportation Group and the A. I. E. E. Committee on Transportation jointly participate in this session.

January 27—10:00 a. m.

C—Symposium on Inductive Coordination

Presiding officer: A. E. Knowlton, chairman of the meetings and papers committee.

Introductory statement by R. F. Pack, vice-president and general manager of the Northern States Power Company.

Trends in Telephone and Power Practise as Affecting Coordination, by W. H. Harrison, American Telephone and Telegraph Company, and A. E. Silver, Electric Bond and Share Company.

Status of Joint Development and Research on Noise-Frequency Induction, by O. B. Blackwell, American Telephone and Telegraph Company, and H. L. Wills, Georgia Power Company.

Status of Joint Development and Research on Low-Frequency Induction, by R. N. Conwell, Public Service Electric and Gas Company, and H. S. Warren, American Telephone and Telegraph Company.

Status of Cooperative Work on Joint Use of Poles, by J. C. Martin, Midwest Utilities Company, and H. L. Huber, American Telephone and Telegraph Company.

Closing statement by Bancroft Gherardi, vice-president and chief engineer of the American Telephone and Telegraph Company.

January 27—2:00 p. m.

D—Session on Protective Devices

Presiding officer: Raymond Bailey, chairman of the committee on protective devices.

An Experimental Lightning Protector for Insulators, by J. J. Torok, Westinghouse Electric & Manufacturing Company.

Field Tests on Thyrite Lightning Arresters Using Artificial Lightning of 1,500,000 Volts, by K. B. McEachron and E. J. Wade, General Electric Company.

Series Resistance Method of Increasing Transient Stability Limit, by R. C. Bergvall, Westinghouse Electric & Manufacturing Company.

Trend in Development of Modern Circuit Interrupters, by J. B. MacNeill, Westinghouse Electric & Manufacturing Company.

Philo 1930 Oil Circuit Breaker Tests (aims, set-up and results from a system and operating point of view), by Philip Sporn and H. P. St. Clair, American Gas and Electric Company.

The Oil-Blast Circuit Breaker, by D. C. Prince and W. F. Skeats, General Electric Company.

Field Tests on Standard and Oil Blast Explosion Chamber Oil Circuit Breakers, by R. M. Spurck and H. E. Strang, General Electric Company.

January 28—10:00 a. m.

E—Session on Power Transmission

Presiding officer: P. H. Chase, chairman of the committee on power transmission and distribution.

Traveling Waves on Transmission Systems, by L. V. Bewley, General Electric Company.

Impulse Tests on Substations, by A. S. Brookes and R. N. Southgate, Public Service Electric and Gas Company, and W. G. Roman and E. R. Whitehead, Westinghouse Electric & Manufacturing Company.

Lightning Investigation on a Wood-Pole Transmission Line, by J. J. Torok, Westinghouse Electric & Manufacturing Company, and R. R. Pittman, Arkansas Power and Light Company.

1929 Lightning Experience on the 132-Kv. Transmission Lines of the American Gas and Electric Company, by Philip Sporn, American Gas and Electric Company.

Attenuation and Successive Reflections of Traveling Waves, by James C. Dowell, General Electric Company.

January 29—10:00 a. m.

F—Session on Industrial Power Applications

Presiding officer: C. W. Drake, chairman of the committee on general power applications.

Electron Tubes in Industry, by W. R. King, General Electric Company.

Automatic Regulators in Industry, by J. H. Ashbaugh, Westinghouse Electric & Manufacturing Company.

Electrical Distribution Systems for Industrial Plants, by W. J. McClain and Louis T. Klauder, consulting engineers.

The Synchronous Motor with Phase-Connected Damper Winding as a Drive for High-Torque Loads, by M. A. Hyde, Jr., Westinghouse Electric & Manufacturing Company.

The Design and Application of Synchronous Motors to Meet Special Requirements, by D. W. McLenegan and A. G. Ferriss, General Electric Company.

Weather Making—A Public Service and a New User of Power, by D. C. Lindsay, Carrier Engineering Corporation.

January 29—2:00 p. m.

G—Session on Transportation

Presiding officer: Sidney Withington, chairman of the committee on transportation.

Lackawanna Suburban Electrification, by E. L. Moreland, Jackson and Moreland, Engineers.

Motive Power for Suburban Electrification, by Charles Kerr, Jr., Westinghouse Electric & Manufacturing Company.

Transverse Fissure Detector Car, by H. C. Drake, Sperry Products, Inc.

Inclined Catenary Calculations, by B. M. Pickens, Westinghouse Electric & Manufacturing Company.

Design of Catenary System for Cleveland Union Terminal, by N. F. Clement and E. E. Richards, Cleveland Union Terminals Company.

January 29—2:00 p. m.

H—Session on Electric Welding

Presiding officer: P. P. Alexander, chairman of the committee on electric welding.

Some Experiments with Arcs between Metal Electrodes, by G. M. Shrum and H. G. Wiest, Jr., General Electric Company

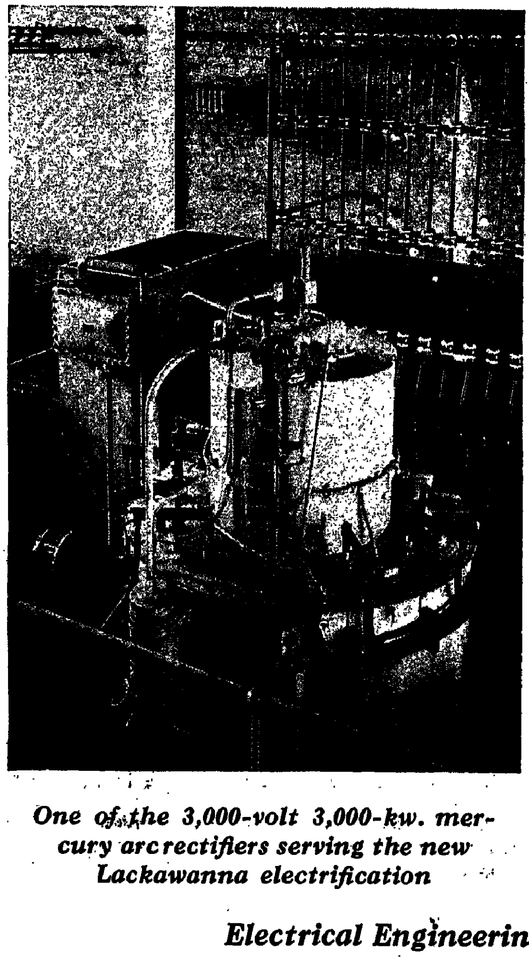
An Improved Arc-Welding Generator, by J. H. Blankenbuehler, Westinghouse Electric & Manufacturing Company.

The Neutralized Welder—A Means of Controlling Transients, by F. Creedy, Lehigh University.

A System for D-C. Arc Welding, by S. R. Bergman, General Electric Company.

Resistance Welding of Motor Frames, by Malcolm Thomson, General Electric Company.

Electric Resistance Brazing, by Samuel Martin, Jr., General Electric Company.



One of the 3,000-volt 3,000-kw. mercury arc rectifiers serving the new Lackawanna electrification

January 30—10:00 a. m.

I—Session on Research

Presiding officer: L. W. Chubb, chairman of the committee on research.

Some Electrical Characteristics of Cable Oils, by H. H. Race, General Electric Company.

The Conductivity of Insulating Oils—II, by J. B. Whitehead, Johns Hopkins University.

Fundamental Properties of Impregnated Paper, by J. B. Whitehead and W. B. Kouwenhoven, Johns Hopkins University.

Traffic Control by Light Beams, by R. C. Hitchcock, Westinghouse Electric & Manufacturing Company.

Commutation and Current Collection in Hydrogen, by R. M. Baker, Westinghouse Electric & Manufacturing Company.

The Helical Groove, by G. M. Little, Westinghouse Electric & Manufacturing Company.

Studies in Non-Linear Circuits, by C. G. Suits, General Electric Company.

January 30—2:00 p. m.

J—Session on Electrical Machinery

Presiding officer: P. L. Alger, chairman of the committee on electrical machinery.

Mercury Arc Rectifier Research, by A. W. Hull and H. D. Brown, General Electric Company.

Effect of Transient Voltages on Power Transformer Design—III, by K. K. Palueff, General Electric Company.

Stationary Flow of Heat in Large Turbine Generators, by C. Richard Soderberg, Westinghouse Electric & Manufacturing Company.

Induction-Motor Slot Combinations, by Gabriel Kron, United Research Corporation.

The Pulling into Step of a Salient-Pole Synchronous Motor, by H. E. Edgerton and Paul Fourmarier, Massachusetts Institute of Technology.

◆

Professional Committee Appointed to Study Engineer Licensing

To provide for closer cooperation of the Institute with the American Engineering Council in all matters connected with the improvement of the general status of the engineering profession, President Schuchardt was, in March 1929, authorized by the Board of Directors to appoint a representative to serve on the Council's committee on engineering and allied technical professions, with the understanding that this representative would become chairman of an Institute committee if it later became desirable to establish a separate committee. H. A. Kidder, superintendent of motive power, Interborough Rapid Transit Co., New York, was appointed the A. I. E. E. representative.

The Board of Directors, in August 1929, authorized the president to appoint a committee on the engineering profession to consider various matters affecting the status of the engineering profession, to cooperate with the American Engineering Council committee on engineering and allied technical professions, and to assume the duties of the A. I. E. E. committee on licensing of engineers which was, at the same time, discontinued. To serve with Chairman Kidder, President Smith appointed T. F. Barton, H. P. Charlesworth, and John C. Parker.

President Lee reappointed the four named above for the present administrative year, and, in accordance with authority granted by the Board of Directors in October 1930, has enlarged the committee to include the membership given below:

H. A. Kidder, (Chairman), supt. of motive power, Interborough Rapid Transit Co., 600 West 59th St., New York, N. Y.

J. P. Alexander, Boston manager, Westinghouse Elec. & Mfg. Co., 10 High St., Boston, Mass.

T. F. Barton, district engineer, General Electric Co., 120 Broadway, New York, N. Y.

B. M. Brigman, dean, Speed Scientific School, University of Louisville, Louisville, Ky.

H. P. Charlesworth, vice-president, Bell Telephone Laboratories, Inc., 463 West St., New York, N. Y.

L. F. Leurey, consulting electrical engineer, 58 Sutter St., San Francisco, Calif.

L. W. Morrow, editor, *Electrical World*, Tenth Ave. at 36th St., New York, N. Y.

John C. Parker, vice-president in charge of engineering, Brooklyn Edison Co., Inc., 380 Pearl St., Brooklyn, N. Y.

John R. Price, professor of electrical engineering, University of Wisconsin, Madison, Wis.

Herbert S. Sands, consulting engineer, 1115 First National Bank Building, Denver, Colo.

Maurice R. Scharff, consulting engineer, Main & Co., accountants and auditors, First National Bank Building, Pittsburgh, Pa.

H. H. Schoolfield, chief engineer, Pacific Power & Light Co., 607 Public Service Bldg., Portland, Oregon

W. I. Slichter, professor of electrical engineering, Columbia University, New York, N. Y.

J. B. Thomas, vice-president, Electric Service Co., Fort Worth, Texas

Although this committee has several very important fields of activity, it is at present devoting its principal efforts to cooperation with other organizations in the development of suitable provisions for the licensing of engineers. Through this committee and its close cooperation with the American Engineering Council committee named above, the Institute is in position to participate actively in efforts to solve problems affecting the status of the engineering profession.

◆ ◆ ◆

A. I. E. E. Nominating Committee Announces Official Candidates for 1931

A COMPLETE official ticket of candidates for the Institute offices that will become vacant August 1, 1931, was selected by the national nominating committee which met at Institute headquarters, New York, December 5, 1930. This committee consists of fifteen members, one selected by the executive committee of each of the ten geographical districts, and the remaining five elected by the board of directors from its own membership.

The following members of the committee were present: W. L. Amos, Toronto, Ont.; K. A. Auty, Chicago, Ill.; H. V. Carpenter, Pullman, Wash.; H. P. Charlesworth, New York, N. Y.; A. B. Cooper, Toronto, Ont.; Herbert S. Evans, Boulder, Colo; E. A. Hester, Pittsburgh, Pa. (alternate for E. C. Stone of Pittsburgh); H. A. Kidder, New York, N. Y.; E. B. Meyer, Newark, N. J.; J. S. Palmer, Kansas City, Mo.; W. S. Rodman, Charlottesville, Va. (alternate for E. D. Wood, of Louisville, Ky.); Harold B. Smith, Worcester, Mass.; C. E. Stephens, New York, N. Y.; R. G. Warner, New Haven, Conn.; W. L. Winter, San Francisco, Calif.; and F. L. Hutchinson, New York, N. Y., Secretary of the Committee. Past-president Harold B. Smith was elected chairman of the Committee.

The following is a list of the official candidates as selected by the committee:

For President

Charles E. Skinner, Assistant Director of Engineering, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pennsylvania.

For Vice-Presidents

Middle Eastern District: W. B. Kouwenhoven, Professor of Electrical Engineering and Assistant Dean, School of Engineering, Johns Hopkins University, Baltimore, Maryland.

Southern District: W. E. Freeman, head, Department of Electrical Engineering, Assistant

Dean of College of Engineering, University of Kentucky, Lexington, Kentucky.

North Central District: Paul H. Patton, Telephon Engineering, Northwestern Bell Telephone Company, Omaha, Nebraska.

Pacific District: A. W. Copley, Engineering Manager, Pacific Coast District, Westinghouse Electric and Manufacturing Company, San Francisco, California.

Canada District: L. B. Chubbuck, Switching Equipment Engineer, Canadian Westinghouse Company, Ltd., Hamilton, Ont., Canada.

For Directors

L. W. Chubb, Director of Westinghouse Research Laboratories, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pennsylvania.

B. D. Hull, Engineer, Southwestern Bell Telephone Company, Dallas, Texas.

H. R. Woodrow, Electrical Engineer, Brooklyn Edison Company, Brooklyn, New York.

For National Treasurer

W. I. Slichter, Professor of Electrical Engineering, Columbia University, New York, N. Y.

The Constitution and By-laws of the Institute provide that the nominations made by the national nominating committee shall be published in the January issue of the Institute Journal. Provision is made for independent nominations as indicated in the following excerpts from the Constitution and By-laws:

Constitution

Sec. 31. Independent nominations may be made by a petition of twenty-five (25) or more members sent to the National Secretary when and as provided in the By-Laws; such petitions for the nomination of Vice-Presidents shall be signed only by members within the District concerned.

By-Laws

Sec. 23. Petitions proposing the names of candidates as independent nominations for the various offices to be filled at the ensuing election, in accordance with Article VI, Section 31 (Constitution), must be received by the Secretary of the National Nominating Committee not later than February 15 of each year, to be placed before that Committee for the inclusion in the ballot of such candidates as are eligible.

On the ballot prepared by the National Nominating Committee in accordance with Article VI of the Constitution and sent by the National Secretary to all qualified voters during the first week in March of each year, the names of the candidates shall be grouped alphabetically under the name of the office for which each is a candidate.

National Nominating Committee
(*Signed*) By F. L. Hutchinson,
Secretary.

C. E. Skinner

Charles Edward Skinner, assistant director of engineering for the Westinghouse Electric & Manufacturing Co., a manager of the Institute (1915-19) and one of its vice-presidents (1919-20), was born on a farm near Redfield, Ohio, May 30, 1865. He was educated at Ohio University and Ohio State University, being graduated from the latter with an M. E. degree with the class of 1890. He worked his way through the university, partly as a helper at the Ohio Experimental Station Dairy and partly as a machinist in the university shops. In August, after graduating in June, he joined the organization of the Westinghouse Electric & Manufacturing Company as a machinist in charge of the manufacture of railway controllers. Early in 1891 he was put in charge of all insulation design, as well as testing. In addition to the insulation work, he took up magnetic testing and the development of magnetic materials in 1892, and retained charge of this work for many years.

In 1906 Dr. Skinner organized for the Westinghouse company the research division of the engineering department, and was responsible for the organization and equipment of the chemical, physical and process laboratories, as well as the high-tension test laboratory.

Through his efforts a laboratory for more fundamental research was determined upon in 1915 and he had charge of the building, equipping, and organization of the personnel of this laboratory. In 1920 he was made manager of the research department, taking direct and individual charge of the research laboratory for the next two years. In 1922 he was made assistant director of engineering.

Dr. Skinner went to Brussels in 1906 as American representative of the International Association for Testing Materials. In 1915 he was a special delegate from the A. I. E. E. to confer with the British Engineering Standards Committee. In 1920 he was chairman of the American Delegation to the Brussels meeting of the International Electrotechnical Commission, and held a similar position at the meeting of that commission in Geneva, Switzerland, in 1922. He was a member of the American delegation to the International Electrotechnical Commission meeting in London in 1924, The Hague in 1925, New York in 1926, and Bellagio in 1927. He was a delegate to the World Power Conference in London in 1924.

Dr. Skinner was chairman of the American Engineering Standards Committee the years of 1925, 1926, and 1927. He was elected chairman of the committee for the organization of the International Standards Association and represented the United States at the London conference of the I. S. A. in 1926.

Dr. Skinner was a member of the Engineering Council throughout its life, and is a member of the American Engineering Council, its successor. He was chairman of a special committee appointed by the Electrical Manufacturers Council, at the request of Herbert Hoover, then Secretary of Commerce, to work with the Department of Commerce and Bureau of Standards. He has been a member of the standards committee of the Institute for many years. As past chairman of the American Engineering Standards Committee he becomes a member of the board of directors of the American Standards Association.

Dr. Skinner is a Fellow of the American Institute of Electrical Engineers, member of the Franklin Institute, American Society for Testing Materials, Fellow of the American Association for the Advancement of Science, member of the American Society of Mechanical Engineers, member of the Engineers' Society of Western Pennsylvania, member of the National Electrical Manufacturers Association, the American Physical Society, the American Electrochemical Society, the Philosophical Society of Pittsburgh, th Engineers' Club of New York, the United States committee of the International Electrotechnical Commission, and the University Club of Pittsburgh. He was appointed a delegate to the International Engineering Congress held in Japan in October, 1929, acting as chairman of the American Electrochemical Society's delegation and a member of the American Standards Association's delegation to th congress. In 1927 he received the honorary degree of Doctor of Science from Ohio University.

In addition to those already mentioned Mr. Skinner has served on the following committees of the Institute: Edison medal, executive, public policy, principles of professional conduct, meetings and papers, research, electrical machinery, educational, and electrophysics.

W. B. Kouwenhoven

William Bennett Kouwenhoven was born at Brooklyn, N. Y., January 13, 1886. He received his early education at the Polytechnic Institute of Brooklyn and was graduated with the Degree of E. E. *cum laude* in 1906 and a year later received the degree of M. E. from the same institution. Early educational experience was obtained acting as instructor in electrical engineering at the Polytechnic Institute of Brooklyn for four years subsequent to his graduation. The next three years were devoted to study in Germany under Professor Arnold at the Karlsruhe Technische Hochschule, Baden, Germany, where the Degree of Doktor Ingenieur *magna cum* was conferred on him in 1913.

During the course of Prof. Kouwenhoven's professional career, he has been known to be an able educator, diligent research worker and a very capable engineer. In addition to the foregoing educational experience, he served for a year as instructor in electrical engineering at Washington University and in the year 1914 was appointed an instructor in electrical engineering at Johns Hopkins University and to date is connected with the latter institution. His progress was rapid and during the year 1917 he was promoted to the rank of associate in electrical engineering, in 1919 he was promoted again, to the rank of associate professor, and in 1930 he was made professor of electrical engineering and assistant dean of the engineering school.

Professor Kouwenhoven was in charge of the electrical engineering department at Johns Hopkins University and acted as instructor in the Reserve Officers Training Corps unit and held the rank of Captain during the war. He served part-time acting as a consulting electrical engineer at the Bureau of Standards.

From 1919 to 1920, while on leave from Johns Hopkins University, he was master engineer in the employ of the Winchester Repeating Arms Company and in charge of the installation of a plant for the manufacture of batteries and flashlights.

Professor Kouwenhoven has been very active in the Institute and other engineering societies. He became an Associate of the Institute in 1906 and was transferred to the grade of Member in 1922. He has been a member of the following Institute committees: communication, electrophysics, instruments and measurements, Sections, and the committee on coordination of institute activities. For the past three years he served as chairman of the sections committee and at present he is chairman of the Baltimore Section.

In addition to his Institute activities, many noteworthy publications, too numerous to enumerate, along research lines and on the subject of instruments and measurements, have been credited to his name. Professor Kouwenhoven is a member of the A. S. T. M. and has served as vice-chairman of the committee on magnetic testing. He is also a member of the Johns Hopkins Club and the Baltimore Engineers Club.

W. E. Freeman

William Edward Freeman was born in Fayette County, Ky., September 25, 1880. After obtaining his early education in the schools of Fayette County he attended Transylvania College and received his A. B. Degree in 1901. Technical education was obtained at the University of Kentucky, where he received the degree of B. M. E. in 1904 and later, in the year 1912, an E. E. degree was conferred on him.

Additional technical training by taking the apprentice course while in the employ of the Western Electric Company was obtained after he had received his B. M. E. degree from the University of Kentucky. The first years of his experience were obtained in the shops and the drafting department at the Chicago plant, which were followed by five and one-half years work on engineering telephone apparatus design in Chicago and in the Bell Laboratories at New York. With his good technical background and very capable manner, a number of pieces of communication apparatus were developed by Mr. Freeman during the course of his work.

In 1911 he left the engineering department of the Western Electric Company to take a position as head of the electrical engineering department at the University of Kentucky. There he was known to be a capable educator and all who had contact with him, both students and associates, benefited by this contact and his friendship. From May, 1920, to August, 1921, he supervised commercial training with the Westinghouse Electric & Manufacturing Company and during the following year acted as dean of the Engineering college at the University of Kentucky. In 1922 he was made assistant dean of the college of engineering and head of the department of electrical engineering at that university and to date is affiliated with the same institution in the same capacities.

Professor Freeman became an Associate of the Institute in 1911 and was transferred to the grade of Member in 1926, and at present he is the Branch counselor at the University of Kentucky. He is a member of the S. P. E. E. and a past-president of its Kentucky Section, a member of Kappa Alpha, Tau Beta Pi, Lamp and Cross, Masons, and Rotary Club. He is now president of the Lexington Rotary Club.

P. H. Patton

Paul Harsha Patton was born October 3, 1873, at Harshaville, Ohio. His early education was obtained at the schools in Denver and through his perseverance and initiative his technical aspect was broadened by intensive study and reading, a large part of which was night work.

Broad and varied experience was obtained in the communication field and Mr. Patton has devoted many years of work in the testing, installation, operating and management of communication companies. His career began as a telephone installer and test man in Denver in the year 1891, followed by ten years of maintenance and installation experience of multiple switchboards. Part of the time was devoted to lighting and power systems of central offices, toll switching, party line ringing and simplex telegraph and phantom equipment. In 1903 he served as superintendent of the fire and police telegraph systems and as chief inspector for enforcement of the National Electric Code, as well as supervising street lighting in the city of Omaha. During the following year he served as general superintendent of the U. S. Telephone and Telegraph Company, Waterloo, Iowa.

In 1905 he became general equipment foreman of the Nebraska Telephone Company and later was appraisal engineer, serving on the Nebraska State Railway Communication Committee for the Development of Telephone Plant Cost Units. In 1909 he became division engineer in responsible charge of engineering plans, specifications and estimates for all types of telephone plants. He was a member and treasurer of the Omaha and Council Bluffs electrolysis survey committee, a director, vice-president and president of the Omaha Technical Club, as well as a member and secretary of the Nebraska Joint Committee on Physical Relations between Electrical Supply and Signal Lines.

Mr. Patton was a member of the organization committee of the Engineers' Club of Omaha when it was organized in 1923, and has been active in the work of the club since that time, serving it in the capacities of member, director, treasurer, and president.

Mr. Patton became an Associate of the Institute in 1918 and was transferred to the grade of Member in 1925. He was a member of the formation committee for the organization of the Nebraska Section of the A. I. E. E. His long, continuous service with the telephone company, together with his joint work and many other activities, has made him a prominent figure in the communication field.

A. W. Copley

Almon Warren Copley was born in Clay Center, Kansas, January 13, 1883. Immediately after completing his electrical engineering course at the University of Kansas he entered the employ of the Westinghouse Electric & Manufacturing Company as an engineering apprentice at East Pittsburgh, Pa., and he has been in the service of that company continuously since that time.

During the course of his professional career, Mr. Copley obtained broad engineering experience. In particular, his prominent work in power transmission and inductive interference in connection with railway electrification has made him one of the recognized leaders in this subject among the engineers of the country. His other experiences consisted chiefly of designing instruments, watthour meters, relays and other similar devices. In 1913 he was in charge of designing automobile starting, lighting, and ignition equipment.

Because of his excellent character and ability, his advancement in the engineering field was unusually rapid. In 1915 he became general engineer, dealing particularly with special problems on railway electrification and general power and distribution systems. In 1921 he was made general engineer for the Pacific Coast and in 1925 he became manager of the engineering division of the San Francisco Office, dealing with engineering in all classes of electric apparatus. In 1928, upon the formation of the Pacific Coast district of the company, he was made engineering manager for the district.

Mr. Copley became an Associate member of the Institute in 1904 and was transferred to the grade of Fellow in 1926. He has ably served on the communication committee as well as on the committee on power transmission and distribution. He has been active in Institute affairs and is well known to the membership. In addition to his Institute activities he is also a member of the Pacific Coast Electrical Association, the Engineers' Club of San Francisco, and the University Club of Pittsburgh.

L. B. Chubbuck

Leonard Burrows Chubbuck was born in Ottawa, Canada, and received his college education at the University of Toronto. He took his B. A. Sc. degree in 1900 and E. E. degree shortly afterward.

Immediately after graduation he entered the employ of the Westinghouse Electric & Manufacturing Company at East Pittsburgh, first in the drafting office and later in the power division of the engineering department. His work included switching equipment design, starting from the early days of air and oil circuit breakers.

In 1909, after nine years' experience with the Westinghouse Electric & Manufacturing Company he was transferred to the Canadian Westinghouse Company at Hamilton, Ontario, where he has been in charge of the engineering department section handling switching equipment, control, circuit breakers, etc. His first work in Canada comprised the Westinghouse switching equipment for the first stations of the Ontario Hydro Electric Commission when 110,000-volt equipment was designed and installed with very great respect. Since that time Mr. Chubbuck has been intimately connected with the switching equipment design of most of the later large hydroelectric plants throughout Canada. He has taken out various patents on disconnecting switches, etc.

Mr. Chubbuck was an Associate of the Institute for the periods 1902-1909 and 1918-1926 at which time he was transferred to the grade of Member. He has served as chairman of the Toronto Section, was Section delegate to the Chicago and to the White Sulphur Springs conventions of the A. I. E. E. and was a member for some years of the committee on protective devices.

Various engineering articles by Mr. Chubbuck have been published in the *Electric Journal*, *Electrical News*, etc., and he has lectured before the Engineering Institute of Canada, Canadian Electrical Association and Toronto Section of the A. I. E. E. He is much interested in sports and is a past president of the Burlington and of the Hamilton Tennis Clubs.

L. W. Chubb

L. Warrington Chubb, son of the late Col. Chas. St. J. Chubb, was born in Fort Yates, Dakota, on October 22, 1882. He obtained his common school education at Cheyenne, Wyoming, and Columbus, Ohio. In 1901, he entered Ohio State University and four years later was graduated with the degree of M. E. in E. E. In 1905, he entered the employ of the Westinghouse Electric & Manufacturing Company at East Pittsburgh, as an engineering apprentice. In 1909, he was engaged in the development and application of magnetic materials. Before the organization of an isolated research department at the Westinghouse company he had charge of advance development work on electrotechnical problems and new developments.

Mr. Chubb has been very active in standardization, both national and international, and in committee work of the leading technical societies. Twice he has been sent to London and Brussels as a delegate of the International Electrotechnical Commission. His wide experience in many pioneer fields of development work has resulted in his being awarded about two hundred patents in electrical, mechanical, chemical and electrochemical and welding fields, and for various types of instruments.

In 1920, when the Westinghouse company organized its radio engineering department, Mr. Chubb was appointed manager of that department. He continued in that capacity until Jan. 1, 1930, when the radio activities of the Westinghouse and General Electric companies and the Radio Corporation of America were consolidated and concentrated at Camden, New Jersey, at which time he was appointed assistant vice-president of engineering. In June, 1930, he returned to East Pittsburgh as Director of the Westinghouse Research Laboratories.

He has been active in the Institute for more than twenty years and presented numerous papers before its meetings. He also is a member of the National Electric Light Association, American Railway Association, International Electrotechnical Commission, American Standards Association, Illuminating Engineering Society, American Association for the Advancement of Science, American Physical Society, and the Franklin Institute of Pennsylvania.

B. D. Hull

Blake D. Hull was born in Galesburg, Michigan, September 12, 1882, and moved to Kansas at an early age. He received his grade and preparatory education at Delphos, Kansas and graduated from the University of Kansas in 1905 with the degree of B. S. in Electrical Engineering. Since that date he has been in the employ of the Southwestern Bell Telephone Company in various branches of engineering work. At the present time he is chief engineer for that company for the state of Texas. He is past vice-president of the seventh geographical district of the Institute. He is first vice-president of the Dallas Technical Club and President of the Dallas Electrical Club. He is a member of the Institute of Radio Engineers. In addition to his business and technical activities he is a member of the Dallas Country Club, a Mason, and a member of the diaconal of the Highland Park Presbyterian Church.

H. R. Woodrow

Harry Roy Woodrow was born in Luverne, Minnesota, April 15, 1887. After finishing his elementary school training in Des Moines, Iowa, he entered Drake University and graduated with the degree of B. S. in 1909. He continued his education at the University of Illinois under a scholarship and received the degree of M. S. with physics as major in 1911.

Mr. Woodrow joined the electrical engineering staff of The New York Edison Company in 1911 and continued his work with that organization until 1920, having advanced during the period to the position of assistant electrical engineer. During 1921 and 1922 he was in engineering work with Stone & Webster, Inc., and the Westinghouse Electric & Manufacturing Company.

During 1922 Mr. Woodrow joined the staff of the Brooklyn Edison Company in the position of assistant electrical engineer and still is with that organization, now occupying the position of electrical engineer.

Mr. Woodrow is a Fellow of the Institute and a member of the National Electric Light Association and has held the following positions in the engineering activity of these two organizations:

Chairman of the protective devices committee, A. I. E. E., 1921-25; chairman of the committee on transmission and distribution, A. I. E. E., 1928-30; chairman of the electrical apparatus committee, N. E. L. A., 1927; member of the executive committee of the Engineering Section, N. E. L. A., 1928-29; chairman of the sectional committee on lightning arresters, American Standards Committee, 1924; member of the committee on electricity distribution and use, Assoc. of Edison Illuminating Companies, 1924-25; member of the committee on electric switching and switchgear, Assoc. of Edison Illuminating Companies, 1929-30.

Mr. Woodrow holds a number of patents on electrical connections and devices. He is a member of Phi Beta Kappa, Sigma Psi and Tau Psi fraternities and a member of the Engineers Club of New York and the Crescent Club of Brooklyn.

Walter I. Slichter

Walter Irvine Slichter was born in St. Paul, Minnesota, May 7, 1873, and was graduated at Columbia University in 1896 with an E. E. degree.

He entered the employ of the General Electric Company as a student in July, 1896, and the following year was transferred to the office of Dr. C. P. Steinmetz, where he was engaged for a year in carrying on experimental work, tests and calculations on various subjects. During the following two years, he was engaged in designing induction motors, alternators, rotary converters, transformers and special experimental apparatus. For a number of years thereafter he devoted most of his time to the design of electrical machinery and, more particularly, the equipment of electric railways.

In 1910, he was appointed professor of electrical engineering and head of that department at Columbia University, which position he still fills.

During the war he was civilian director of the Air Service school for radio officers at Columbia University. Since 1914, Professor Slichter has devoted considerable time to instruction in electrical engineering to naval officers of the postgraduate school of the U. S. Navy, who are detailed for study at Columbia University.

Professor Slichter became an associate in the Institute in 1900 and was transferred to the grade of Fellow in 1912. He was a member of the board of directors from 1918 to 1922, vice-president from 1922 and 1924, and has been an active worker upon several of the important committees of the Institute. He has been chairman of the meetings and papers committee, of the editing committee, and a member of the finance committee. He is a member of several other engineering and scientific societies, and in 1903 was president of the General Electric Engineering Society, and was instrumental in reorganizing it into the Schenectady Section of the Institute. He also served for several years as treasurer of the Society of Engineers of Eastern New York.

Professor Slichter has presented several papers and discussions upon various engineering subjects before the Institute and other societies, and has published many articles on technical subjects.

Louisville Discussions Summarized in Review

Only discussion submitted in writing in accordance with A. I. E. E. rules governing it, is summarized; complete discussion, together with all papers so approved, will be published in the Transactions. A list of papers presented was published in the November issue of the Journal:

Session on Transmission and Distribution

J. J. Torok discussed "LIGHTNING INVESTIGATION AT ALCOA, TENNESSEE." He pointed out wherein the results obtained at Alcoa, coupled with data from other investigations, aided considerably in establishing a more consistent concept of the origin and manner in which surges appear on the line. He cited that the results obtained bore strong evidence against the induced-voltage theory. Of the hundreds of strokes appearing over or near the line only one or two resulted in a surge which might be harmful in its character. Oscillograms of these surges showed them to be of long duration, 30 to several hundred microseconds instead of one or two to 15 or 20 microseconds, as was the earlier belief. Calculations made from these and other records as a basis determined the probable magnitude of induced surges to be of the order of from 100,000 to 200,000 volts, a value harmless to high-voltage transmission lines. Results bear out the prominence of the direct-strike theory with the need for adequate ground wire protection and low tower and footing resistances.

Records kept by these experimental stations in Tennessee showed that a normal switching surge will seldom exceed three times normal and only rarely rise to four times normal. Such data on switching surges are of great value in that they will indicate the minimum insulation a transmission line can have and still give good operating records.

J. B. MacNeill discussed the statement in E. E. George's paper, "Potential transformers are the best and most economical form of potential supply in the long run." He pointed out that successful operation on many large systems, including relaying, indicated the worth of bushing potential devices when used within their ratings. Low Costs and elimination of high-voltage potential transformers justify their use when possible. Mr. MacNeill explained further that recent improvements in bushing potential devices have reduced phase-angle error considerably over a wide voltage range.

Session on Protective Devices

A discussion submitted by Doctor Wilhelm Lampert on "THE PHYSICAL NATURE OF NEUTRAL INSTABILITY" was read by A. E. Knowlton. Doctor Lampert stated that at frequencies with ratios which compared with the impressed frequency is *not* an integer, an alternating bias is necessary. At even harmonics the ratio of which *is* an integer of the fundamental frequency a bias is not at all necessary. These cases are analyzed in his discussion.

John Auchincloss discussed the effect in practical cases of the neutral phenomena described in the papers on "Y-CONNECTED POTENTIAL TRANSFORMERS." The occurrence of the neutral phenomena described may give rise to very misleading or false conclusions in attempting to interpret certain system conditions from the readings of instruments connected to Y-connected potential transformers. These involve the phase comparison of system voltages for purposes of synchronizing across grounded Y-delta power transformer banks, and the detection of accidental grounds on isolated-neutral systems operating at voltages beyond the range of the ordinary electrostatic ground detector.

Professor Walter L. Upson discussed "THEORY OF ABNORMAL LINE-TO-NEUTRAL TRANSFORMER VOLTAGES." He commented on the different methods of attack in the three companion papers and analyzed Mr. La Pierre's equivalent-circuit phenomena. He believes Mr. La Pierre's theory is no doubt correct and that it is greatly clarified in the last section of the appendix. He calls attention to the lack of directions here which would enable one to predict the type of oscillations which might be expected. A series of actual oscillograms based upon predetermined constants and conditions would be interesting.

W. W. Edson in his discussion inquired about the effect of "NEUTRAL INSTABILITY," or the half- and double-frequency oscillations, on certain installations. One of these installations is three 8050/115-volt star-delta-connected potential transformers operating watthour and power-factor meters. Another was the same installation as above only operating directional relays instead of watthour and power-factor meters.

F. A. Hamilton's discussion of the papers by Messrs. C. T. Weller, C. W. La Pierre, A. Boyajian and O. P. McCarty was read by C. J. Schaus. In addition to the experiences with two applications of grounded-neutral potential transformers on portions of systems necessarily operated underground at certain times described in Mr. Weller's paper, Mr. Hamilton called attention to several other similar cases of the phenomena.

Discussion by J. Fallon on the Physical Nature of Neutral Instability was read by J. J. Thalheimer.

W. W. Edson discussed "POWER TRANSFORMER NOISE—ITS CHARACTERISTICS AND REDUCTION" with particular reference to installations adjacent to a building in residential districts. He suggested placing the transformers in a pit in front of the building. The noise would be reflected upward and would not even be objectionable to residents across the street.

In connection with discussion on "POWER TRANSFORMER NOISE," Sol Naiman suggested that a paper be prepared on the elimination of noise in small motors used for hospital installations.

F. W. Gay discussed "POWER TRANSFORMER NOISE" and suggested several methods for its reduction with a resulting improvement in apparatus design. One method suggests the lowering of densities at which materials are operating during light-load periods by the use of transformer windings in series during those periods, and in multiple during heavy-load periods. Another method of eliminating noise would be to fully enclose the electrical equipment in noise-proof compartments and carry off the heat at several different temperatures by using bodies of volatile fluid each separately sealed.

Session on Power Generation

T. E. Purcell discussed "GOVERNOR PERFORMANCE DURING SYSTEM DISTURBANCES." He cited that tests conducted under his supervision which were reported in a paper entitled "Operating Characteristics of Turbine Governors," presented at the 1930 A. I. E. E. Winter Convention, bore out the same general results as those reported in this paper.

He expressed surprise in finding out that turbines under test, overspeed enough to trip the emergency governors when loads in excess of 60 per cent of the rated capacity were dropped. He referred to recent tests on a 60,000-kw. single-cylinder turbine newly installed. The maximum load of about 70,000 kw. can be suddenly dropped by opening the generator oil circuit breaker without tripping the emergency governor.

E. E. George discussed "GOVERNOR PERFORMANCE DURING SYSTEM DISTURBANCES." He emphasized the importance of the point in the paper about getting machines back into step without taking them off the bus. This results in the saving of time required for re-synchronizing which might be excessive if there is trouble on the system.

Philip Sporn discussed "GOVERNOR PERFORMANCE DURING SYSTEM DISTURBANCES." He pointed out that during a system disturbance the amount of disturbance contributed by the governor itself toward the total disturbance cannot yet be definitely determined.

S. L. Henderson discussed "APPLICATION OF HYDROGEN COOLING TO TURBINE GENERATORS." He pointed out that there is some question whether it is necessary to build these machines explosive-proof. This question can only be answered by experience. He cited that the arrangement of coolers within the confines of the machine would be of interest as the machine is complete in itself and does not require the addition of ducts or cooler supports.

Directors Hold December Meeting

The regular meeting of the Board of Directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, on Thursday, December 4, 1930.

There were present: President W. S. Lee, Charlotte, N. C.—Past President Harold B. Smith, Worcester, Mass.—Vice-Presidents Herbert S. Evans, Boulder, Colo.; W. S. Rodman, Charlottesville, Va.; C. E. Sisson, Toronto, Ont.; H. V. Carpenter, Pullman, Wash.; I. E. Moultrop, Boston, Mass.; H. P. Charlesworth, New York, N. Y.—Directors F. C. Hanker, East Pittsburgh, Pa.; E. B. Meyer, Newark, N. J.; J. Allen Johnson, Buffalo, N. Y.; A. M. MacCutcheon, Cleveland, Ohio; C. E. Stephens, New York, N. Y.; A. B. Cooper, Toronto, Ont.; A. E. Knowlton, New York, N. Y.—National Treasurer W. J. Slichter and National Secretary F. L. Hutchinson, New York, N. Y. Present by invitation: H. A. Kidder, New York, Chairman of the Committee on the Engineering Profession.

Reports of meetings of the Board of Examiners held October 21 and November 18 were presented and the actions taken at those meetings approved. Upon the recommendation of the Board of Examiners, the following actions were taken upon pending applications: 1029 Students were enrolled; 70 applicants were admitted to the grade of Associate; 17 applicants were elected to the grade of Member; 69 applicants were transferred to the grade of Member; 9 applicants were transferred to the grade of Fellow.

Approval by the Finance Committee, for payment, of monthly bills amounting to $26,078.21, was ratified.

A resolution was adopted setting the time and location of the 1931 Annual Meeting of the Institute; namely, Monday, June 22, at Asheville, N. C., during the Annual Summer Convention of the Institute.

Mr. William B. Jackson was reappointed a representative of the Institute on the Engineering Societies Library Board for the four-year term beginning January 1, 1931. Mr. L. T. Robinson was reappointed a representative to serve on the Standards Council of the American Standards Association for the three-year term beginning January 1, 1931, and Messrs. H. H. Henline, H. M. Hobart, and H. S. Osborne were reappointed alternates on the Standards Council for the year 1931.

Approval was given of a plan developed by a joint committee of the Founder Societies and the McGraw-Hill Book Company for the publication by the latter of a series of Engineering Societies Monographs, consisting of manuscripts worthy of publication which have been submitted to the societies but which will not be published by the societies. Messrs. E. B. Meyer and W. I. Slichter were appointed as the Institute's representatives on the Engineering Societies Monographs Committee.

Other matters were discussed, reference to which may be found in this and future issues of the Journal.

◆

A Half Century of Electrical Engineering

In celebration of its fiftieth anniversary, the Western Society of Engineers held a meeting in Pittsburgh, Pa., November 14, at which the progress of engineering achievement during the life of the Society was the keynote of the addresses delivered.

Professor Charles F. Scott, Yale University, covered the field of electrical engineering, describing its major advances step by step, from the advent of engine power in the last century to the outstanding electrical developments of today. With the birth of engine power, the engineering spirit was awakened and in two decades the half dozen engineering schools of 1860 had increased fourscore; yet the engineers of 1880 little realized that a new power would soon be at their service.

The Edison incandescent lamp, announced in 1879, inaugurated the era of electric service which has become almost universal—a second industrial revolution. In 1886 the a-c. system of distribution, sponsored by George Westinghouse, began operation in Buffalo, and with it came the era of long distance transmission.

In the sixties the general communication system with numerous private lines connecting residences, offices, and factories, established a service for person-to-person communication carried on by messenger, printing telegraph, and delivery boy. This system was simplified by invention and about 1878 the telephone exchange was installed. Thirty years ago Marconi's three dots spanning the Atlantic heralded the wireless telegraph. Then came broadcasting. A new public service was inaugurated in the pioneer broadcasting which took place about ten years ago. Frank Conrad working with the amateurs discovered that the rejected short wave had vast superiority for long distance service; for instance, talking with Byrd at the South Pole.

One may well ponder over the question —Does electric power, or electric communication—one serving the physical, the other intellectual—make the greater contribution to our modern life?

In the advance of man, definite stages or epochs are recognized. The use of fire, the bow and arrow, the invention of pottery, the domestication of animals, the use of iron—each gave means of life on a higher plane. The outstanding factor in historic time is the production of power; in plotting a curve of human progress the long level of many centuries changes into high ground as the activities of the 19th century of steam power are reached. But they are only foothills before the rising altitude of the 20th century record. These curves of activity in a score of fields, simultaneously with the shift from muscle to manufactured power, coincide with the increasing use of power in the new ways provided by electricity.

In achievement and in anticipation, the story of electricity during the past half century illuminates the verdict of Herbert Hoover that "Electricity is the greatest tool that ever came into the hands of man."

Treasurer Hamilton Resigns W. I. Slichter Elected

National Treasurer George A. Hamilton, because of illness, has found it necessary to resign his office. With regret, on November 25th, at a special meeting of the Executive Committee the resignation was accepted and Professor Walter I. Slichter of Columbia University was elected to fill the unexpired term ending July 31, 1931.

At a meeting of the Board of Directors held December 4, the action of the Executive Committee was ratified and the following resolution adopted:

> Whereas the resignation of National Treasurer George A. Hamilton, because of illness, was accepted with regret by the Executive Committee at a special meeting held at Institute headquarters on November 25, 1930, and this action has been confirmed at this meeting, be it
>
> Resolved that this Board, acting in behalf of the membership of the Institute, hereby places upon record its high appreciation of Mr. Hamilton's long and loyal service since 1895, as Treasurer of the Institute; also of his many and valuable contributions to the Institute as a charter member, Vice-President 1884-6, and member of the Board of Directors, Executive, Edison Medal and other committees; and extends to Mr. Hamilton its greetings and best wishes.

Memorable Meeting Held by the A. S. M. E.

So many features of the annual meeting of the American Society of Mechanical Engineers held early in December were of technical interest and stimulus that its fruitfulness will no doubt be felt well into the future. Good papers of ample scope in the fields to which they specifically applied were supplemented by the animated general discussion which always makes so strongly for constructive values. The handling of materials, railroad development, machine shop practise, gas and oil power, central station power, aeronautics, refrigeration, and American management in Europe, were a few of the subjects to which the convention gave investigation and with more than two thousand engineers in attendance one may appreciate its significance as a medium for the dissemination of a superabundance of broad and versatile information. Industrial accident prevention was supported in a symposium given under the auspices of the A. S. M. E. standing committee on safety.

In a session on hydraulics, Frank E. Bonner, executive secretary of the Federal water-power commission gave rise to such enthusiasm and support of his cause that a resolution was passed by the society's Council for the appointment of a special "Engineer's Water-Power Policy" committee, on which would serve five men chosen from the national representative bodies—two from American Engineering Council and one each from the mechanical, civil, and electrical engineers. The essence of Mr. Bonner's paper appears elsewhere in this issue.

"The Human Problem" took issue in an address delivered by Professor Elliott Dunlap Smith of Yale, at the annual dinner. It was a challenge to the engineer's unmindfulness of obligation both social and technological, and the animation with which Professor Smith delivered his speech paved the way forcefully for sessions held for the discussion of the stabilization of employment, and of economic and industrial power. A special conference assembled at the request of American Engineering Council presented Colonel Arthur S. Wood, chairman of the President Hoover Emergency Committee for Employment to sponsor industry's efforts to stabilize employment both in the past and during the present crisis. In his address he cited a paper presented in 1886 by Henry R. Towne—an epoch-making document responsible for the inauguration of an entirely new management movement in this country. The greatest hope of solution for the present crisis, Colonel Wood believes, rests with an intelligent and persistent attack of the situation by engineers and economists.

Account of the award of the John Fritz Gold Medal to Admiral David Watson Taylor, Chief Constructor of the United States Navy during the World War, and the conferring of honorary membership in the Society upon Doctor Elihu Thomson, past-president of the Institute, may be found briefly stated in another news column of this issue.

Section delegates, the representatives of localized and important society effort, were also in special convention at this last annual meeting, which has also been voted "the best."

◆

Illumination Commission to Meet in England

President E. C. Crittenden of the U. S. national committee of the International Commission on Illumination reports that the general outline of plans for the session to be held in Great Britain in 1931 is now practically complete. In connection with the commission's sessions there will be an international illumination congress and a tour of inspection to various cities. The whole program will fill the time from Sept. 2 to Sept. 19, 1931.

After registration in London delegates will go to Glasgow for the first session Sept. 4. Meetings will follow in Edinburgh, (Sept. 6), Sheffield, (Sept. 8), Birmingham, (Sept. 10), and finally in Cambridge, (Sept. 13-19). The dates have been chosen to bring the meetings to a close immediately before the three-day celebration of the Faraday centennial in London, which will include a meeting of the Institution of Electrical Engineers and will be followed by the annual meeting of the British Association for the Advancement of Science.

Looking forward to the 1931 sessions, the primary aim of the U. S. committee during the past year has been to arrange for creditable representation at the sessions of American interests,—developments, and opinions. The United States is particularly charged with responsibility for four very important divisions of the commission's work: (1) motor-vehicle lighting, (2) factory and school lighting, (3) aviation lighting, and (4) applied lighting practise in fields not otherwise specifically covered. The last two are new assignments, and in these there has been the keenest interest.

To provide a direct connection between the four committees in charge, a special committee has been formed under the chairmanship of A. L. Powell. This coordinating committee is to assist and advise also those who represent the United States on the 14 projects managed by other national committees, thus serving as a general clearing house for American contributions to the congress and commission sessions outside the scope of the secretariat committees.

On two important questions of standardization the assistance of this commission has been sought during the year by other international organizations. One is the problem of lamp bases and sockets; this has been before the International Electrotechnical Commission for several years.

The second question of international standardization which has been raised falls clearly within the field of the I. C. I. The International committee of weights and measures, which now has jurisdiction over international electrical units and standards, has taken up the problems of photometry also. Its advisory committee on electricity has been authorized to seek the collaboration of the I. C. I.; this action will give a new stimulus to the attempt to agree upon (1) a primary standard of light and (2) a uniform and accepted method of measuring lights of widely diverse colors.

Reverting to the matter of representation from this country at the 1931 session, it should be made clear that participation in the session and the tour of inspection is not limited to those who are now taking part in the work of the Committee. The A. I. E. E. is represented on the U. S. National Committee by A. E. Kennelly, C. O. Mailloux and Clayton H. Sharp.

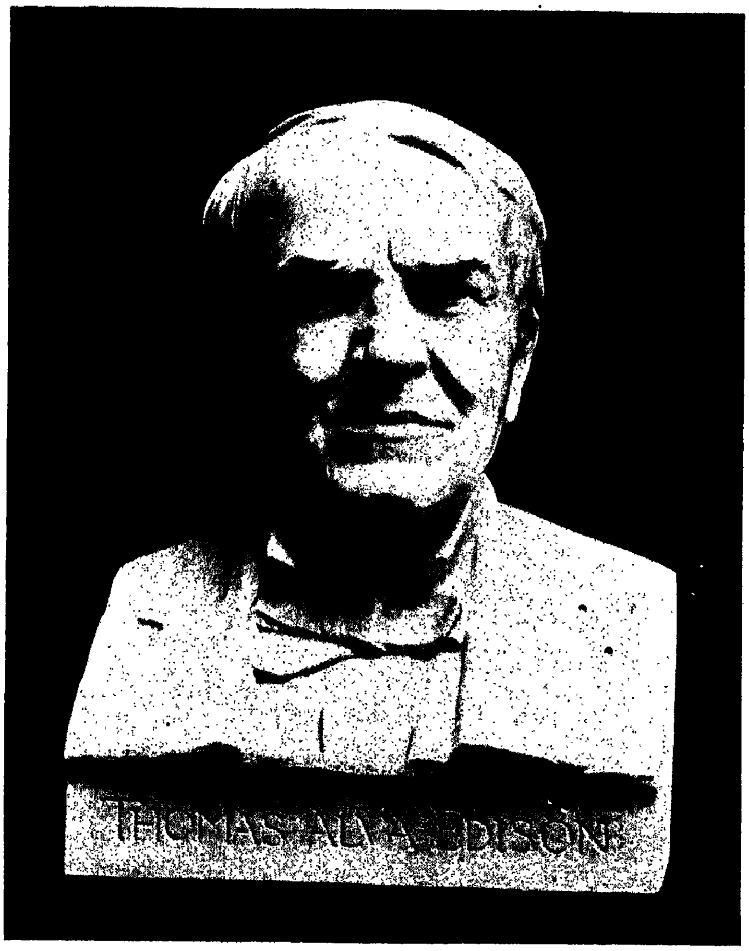
Edison Bust for Deutsches Museum



The Hall of Honor in the Deutsches Museum, Munich, shortly will receive from the United States, with the Institute and the Edison Pioneers as joint sponsors, a marble bust of heroic size of Thomas A. Edison. Formal presentation will be made in Munich by an American delegation, the date of presentation being subject to the convenience of the museum authorities.

District Prizes Awarded at Philadelphia Meeting

J. A. Noertker, of the Cincinnati Street Railway Company's engineering department, and H. F. L. J. Seyler of the Consolidated Gas Electric Light and Power Company of Baltimore, are winners respectively of the Institute's Best Paper Prize and the Initial Paper Prize awards for the year 1929. Mr. Noertker's paper was entitled *Street Railway Power Economics on the Cincinnati System*, and Mr. Seyler's, *Current Characteristics of Constant-Current Transformers During Sudden Changes of Load.* Awards were made October 14, 1930, at the Institute's Middle Eastern District Meeting at Philadelphia.

J. A. NOERTKER

Mr. Noertker is a native of Cincinnati, Ohio, and a graduate of the University of Cincinnati (1928). He entered the employ of the Cincinnati Traction Company as a cooperative student, and after graduation remained with the company in the capacity of "special engineer." In 1927 he was promoted to the position of electrical engineer of the newly organized Cincinnati Street Railway Company.

H. F. L. J. SEYLER

Mr. Seyler is a graduate of York High School, York, Pennsylvania (1923) now doing night school work at Johns Hopkins for a B. S. degree in engineering. He has traveled extensively in this country in the interest of the electric construction department of the Pennsylvania Water and Power Company. Since 1925 he has been in the electric test department of the Consolidated Gas, Electric Light and Power Company engaged in various special tests and investigations on radio interference problems, special studies on constant-current transformers, and series street-lighting circuits; also the effects of corona on fuses, and the characteristics of high-voltage fuses, disconnect switches, oil circuit breakers, etc. Most of his time is now being devoted to special oscillographic work and a generalized study of lightning on the 66-kv. ring of the Consolidated company.

◆ ◆ ◆

Edison Medal Awarded to Dr. Frank Conrad

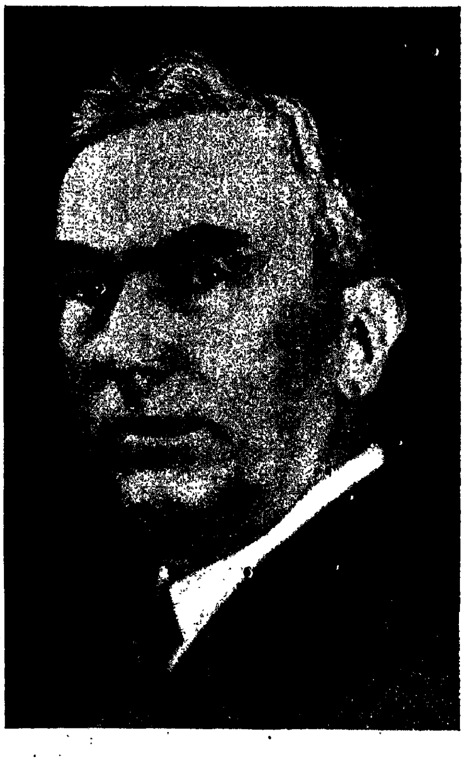
"FOR his contribution to radio broadcasting and short-wave radio transmission" Doctor Frank Conrad, Pittsburgh, Pa., has been given the 1930 Edison Medal Award by the American Institute of Electrical Engineers. It is planned to present the medal to Doctor Conrad on Wednesday evening January 28, 1931, in connection with the annual Winter Convention of the Institute.

The Edison Medal was founded February 11, 1904, by associates and friends of Thomas A. Edison and is awarded annually for "meritorious achievement in electrical science, electrical engineering, or the electrical arts," by a committee consisting of twenty-four members of the Institute.

Since its establishment the medal has been awarded to the following men: Elihu Thomson (1909), Frank J. Sprague (1910), George Westinghouse (1911), William Stanley (1912), Charles F. Brush (1913), Alexander Graham Bell (1914), Nikola Tesla (1916), John J. Carty (1917), Benjamin G. Lamme (1918), W. L. R. Emmet (1919), Michael I. Pupin (1920), Cummings C. Chesney (1921), Robert A. Millikan (1922), John W. Lieb (1923), John W. Howell (1924), Harris J. Ryan (1925), William D. Coolidge (1927), Frank B. Jewett (1928), Charles F. Scott (1929).

Doctor Conrad was born in 1874 in Pittsburgh, Pennsylvania. In 1890 he entered the employ of the Westinghouse Electric and Manufacturing Company in Pittsburgh and his rise in that organization was rapid. After several years as an assistant in the shops he entered the laboratory and during the ensuing stage of his work he invented several forms of switches, lightning arresters, and breakers for use in alternating-current work. He was closely associated with, and later in entire charge of, the arc-lamp design department. This was his first engineering work. Doctor Conrad's connection with radio dates back before the days of broadcasting when he became interested as an amateur in radio reception of time signals and later in radio-telephone transmission by means of vacuum tubes. He established an amateur radio telephone station which later resulted in the development of the Westinghouse station, KDKA.

Doctor Conrad was appointed a general engineer of the Westinghouse organization in 1904 and was promoted to the position of assistant chief engineer in 1921. In 1925 he was awarded the Morris Liebmann Memorial Prize of the Institute of Radio Engineers for his early work in connection with high-frequency transmission.



DOCTOR FRANK CONRAD

He is a Fellow of the Institute of Radio Engineers, a member of the Society of

Automotive Engineers, and a member of the American Association for the Advancement of Science. He received the honorary degree of Doctor of Science in 1928 from the University of Pittsburgh.

◆

Conductivity of Threaded Connections

Measurements have been completed by the Bureau of Standards covering electrical resistance between nuts and bolts, using two radically different types of threads—the American National and the Dardelet—and different materials. Results showed that the contact resistance usually is less than the resistance of a one-inch length of the bolt and that under similar conditions the resistance of the Dardelet thread generally is not more than one-fourth that of the American National thread. Maximum resistances found were for steel bolts of the American National thread, in which, with a stress of 2,000 lb. per sq. in. in the bolts, (about an inch length of bolt), the resistance is about 10 microhms. Minimum stresses were found for copper bolts with Dardelet threads in which, with a stress of 6,000 lb. or more per sq. in., the resistance was approximately 0.02 microhm, equivalent to about 1/64 in. of bolt.

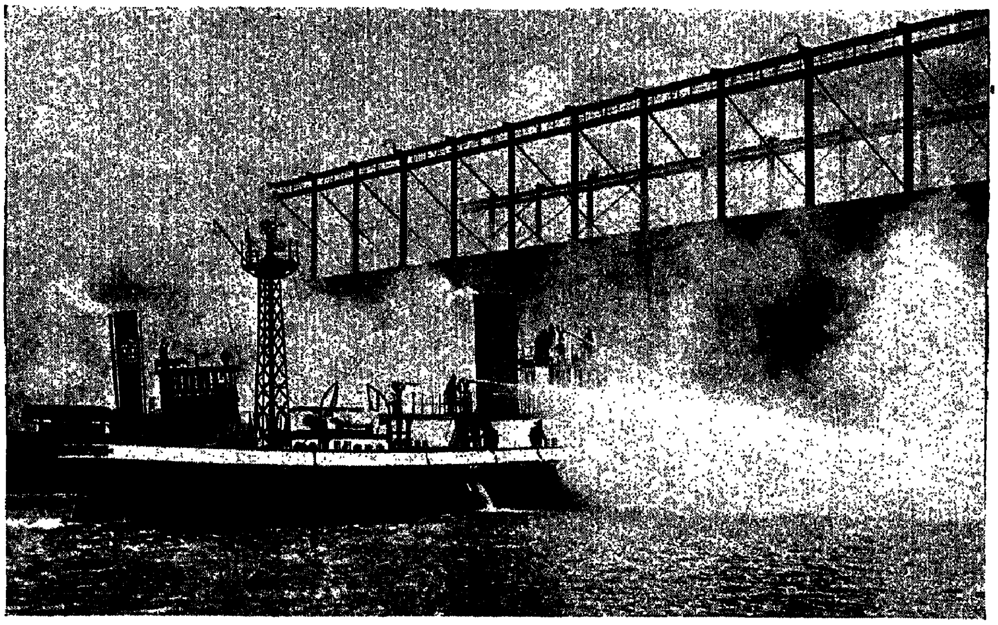
This subject is treated in further detail in Research Paper No. 227, Bureau of Standards.

◆

Dr. Millikan Predicts Added use of Sun's Rays

Science, instead of being even a fractional deterrant to business, as some claim, may prove on the contrary a solution whereby adjustment of present circumstances may be accomplished, is the opinion expressed by Doctor Robert A. Millikan before the second session of the Association of Life Insurance Presidents recently reported convention in New York City. Doctor Millikan's thought according to the account is to use direct sunlight instead of the stored solar energy found in coals and oils. He asserts that if it were possible for the hydrogen in seawater to be combined on the earth's surface with helium, oxygen, carbon, nitrogen, silicon, etc., energy would be released in enormous quantities with no violation of any established thermodynamic law. He sketched a future in which science will "almost indefinitely increase the satisfaction of human wants"; saying, "science creates more jobs than it destroys".

Two-Way Radio Phone Demonstrated by Fire Boat



Possibility of maintaining constant communication with shore headquarters two miles distant was demonstrated recently through the use of a two-way radio apparatus installed on the John Purroy Mitchell flagship of New York City's fire fighting fleet. This is one of the first proofs of effective use of radio communication in connection with the fighting of fires and it is expected that it may result in a saving of thousands of dollars annually. Beside doing away with the necessity of responding to false alarms the two-way system permits centralized direction of marine fire forces and greatly improves coordination with land forces.

In the apparatus used for test demonstration, transmission and reception were carried on alternately by means of a small push button on the telephone transmitter. This push-button controls relays which connect either the transmitter or the receiver with the antenna subject to the will of the operator. The Federal Radio Commission already has authorized reciprocal radio stations for this new utilization of radio facilities; the land station in New York will be designated as WCF and the station aboard the New York fire boat will be WRBE.

◆ ◆ ◆

"Cal.-Tech." to Have Astro-Physics Laboratory

A laboratory devoted to research on astronomical and allied subjects is to be built by the California Institute of Technology, Pasadena, as a part of its new 200-in. telescope observatory, to be located in the adjacent mountains. Equipment for the new astro-physics laboratory was described by Emmett M. Irwin, late of the General Electric Company, in a recent address before a Student Branch Meeting in Pasadena. Mr. Irwin now is engaged in research work at the Institute in Pasadena and is contributing much to the general design for the new laboratory and its equipment.

Two features are of particular interest to the electrical engineer; one, a coelostat tower 75 ft. high, to be used in obtaining spectrographs of the sun. The dome of this tower, holding the collecting mirrors, must of necessity rotate with the sun; it will have an independent electrical system of limited power, but maintained at an accurately constant frequency by the oscillation of a piezo-crystal suitably amplified. For precision, this idea supplants the ordinary clockwork method, which because of reverse power fed back from manually-operated mechanisms, is subject to inaccuracies.

The second unique piece of apparatus which Mr. Irwin's plans include is a 200-kw. solenoid to be used in the investigation of solar spectra under the influence of intense magnetic fields, it being supposed that sunlight reaches us at times through intervening magnetic fields in space which break up the spectrum lines into unusual components. As proposed, the coil used will be of 17-in. diameter and five or six feet high. To keep its dimensions within reason, it must be essentially a high-current instrument; leads to the solenoid will be of ¼-x 6-in. copper bars carried through a special tunnel outside the building about 200 ft., from the generator room to the tower. In a laboratory of this nature space for generator layout is limited and great care must of necessity be exercised, problems of interference being very fully debated. Synchronization of units distributed over the building with the main system will be accomplished by Selsyn equipment.

◆

Can Power Come from Tropic Seas?

Power stored in tropic seas is capable of operating electric generating plants of as much as 25,000-kw. capacity, according to assertion made by Professor Georges Claude, famous French scientist, in a lecture before a recent meeting of the American Society of Mechanical Engineers. Reported in the November 1, 1930, issue of *Science News Letter* is an interesting account of Professor Claude's proposal to build a power plant to utilize the hydroelectric possibilities available through the temperature differences between the surface and the deeper water of southern seas. It is asserted that so far as convertible energy is concerned a given installation could be compared with a 300-ft. waterfall.

According to Professor Claude's proposal such a plant could be located near Santiago de Cuba, and could be of sufficient capacity to meet the normal requirements of several thousands of people. Three million dollars is said to be the approximate cost of developing such a plant. This figure, although somewhat greater in proportion than that of the modern steam-electric plant, is said to compare favorably with other hydroelectric installations, all points considered.

In this process of conversion of ocean waters into usable power it is contemplated that the warm surface water would first be vaporized into steam at a very low temperature; the tepid water not being heated but merely subjected to vacuum. Steam so obtained would be passed through a turbine and thence to a condenser cooled by water drawn from a relatively great depth. Thus the cycle contemplated is similar to that of a normal steam-electric generating plant.

Fritz Gold Medal Awarded Admiral Taylor

Wednesday evening Dec. 3, 1930, at the annual dinner of the American Society of Mechanical Engineers, the John Fritz gold medal was awarded Admiral David Watson Taylor, chief constructor of the United States Navy during the World War.

During his whole active career, lasting from 1881 to Jan. 15, 1923, when he was retired from service at his own request, Admiral Taylor's record has been one of unusual achievement and value to both governmental and professional causes, both nationally and internationally.

◆

Biggest Radio Tube

By the grouping together of several of these huge 200,000-watt radio tubes, former Federal Radio Commissioner O. H. Caldwell (standing) now editor of *Electronics* predicts that the million-watt broadcasting station will become a reality. This giant tube has its grid as well as its plate watercooled, the operation requiring approximately 1,250 gallons of cooling water hourly.

In the hope of overcoming static and thus affording better service for millions of people, especially those located in rural districts, Mr. Caldwell, as Radio Commissioner, urged the use of high powered broadcasting stations, and toward this end the above pictured tube seems to be an important step of accomplishment.

A. S. A. Chooses Dr. Gherardi President

The election of Bancroft Gherardi to the presidency of the American Standards Association was announced at the annual meeting of the association Dec. 11, 1930. He will now assume direction of national and international standardization activities for the organization, a task involving more than 2,000 representatives of some 500 national trade, technical, and governmental bodies. Mr. Serrill's work (Mr. Gherardi's predecessor) included the completion of 46 new national standard, in mechanical, electrical, civil, chemicals mining, and woodworking fields during the past year, with a number of safety codes which are now being used by regulatory bodies, by insurance groups, and by industry in behalf of uniform methods for safeguarding the lives and health of workers.

Others taking office in the association under the coming year's elections are, Cloyd M. Chapman, engineering specialist of New York City, re-elected vice-president and chairman of the A. S. A. Standards Council, and John C. Parker, serving as vice-chairman.

◆

Dr. Thomson A. S. M. E. Honorary Member

Doctor Elihu Thomson, past-president and Honorary Member of the Institute and director and founder of the Thomson Laboratory of the General Electric Company at Lynn, Mass., was awarded honorary membership in the American Society of Mechanical Engineers on Dec. 2, 1930, during that society's annual meeting. The presentation was made by Dr. Ambrose Swasey of Cleveland, a past-president of the A. S. M. E.

The importance of Dr. Thomson's scientific and engineering achievements already has received recognition by representative societies of many countries in the form of medals, fellowships and official position. His conspicuous work in behalf of Institute activities is too well known to require further publicity here.

◆

A Tube the Equivalent $5 Billion of Radium

"Wonders of a new X-Ray machine—a 650,000-volt tube" was the subject of Dr. R. A. Millikan's talk before the Radiological Society of North America at its late meeting as reported in the daily press. The tube's potentialities in the fields of medicine, physics and engineering, the noted scientist said, are undeterminable at present.

Its rays approximate the gamma rays of radium, and what may lie ahead in its application for the penetration of metals and of non-homogeneous masses and the molecular structure of human tissues remains for the future to reveal.

New Photoflash Lamp Makes Photography Safe

It is claimed that the dangers from flashlight powders used in photographic work have been conquered to no inconsiderable degree in the production of what will be known as "photoflash" lamp. It is a Westinghouse discovery whereby an ordinary incandescent lamp is reported to be converted into one which will produce a four-million-candlepower flash free of the danger of fire to any inflammable surroundings to which its service may be destined.

There is no smoke, no flame; a glass confines the chemical reaction and all residue. Being similar to the 100-watt household lamp, the photoflash lamp is claimed to operate on any ordinary electric light socket or even from the ordinary handflashlight battery when equipped with the household lamp socket.

Standards

Standardization Projects Reviewed

For those interested in the status of the various electrical standardization projects which are being carried on under American Standards Association procedure, there appears in the November issue of the *A. S. A. Bulletin* a detailed statement covering 35 undertakings. The Institute is serving as sponsor or joint sponsor in 23 of these and is represented in many of the others. Copies of the bulletin may be obtained by addressing A. S. A. headquarters, 29 West 39th Street, New York, N. Y.

A. S. T. M. Standards

The 1930 edition of the triennial book of A. S. T. M. standards has just been issued. It contains 430 standards adopted by the Society and is issued in two parts:—Part I—Metals—standards relating to steel, wrought iron, pig and cast iron, ferro alloys, non-ferrous metals, miscellaneous. Part II—Non-Metals—standards relating to cement, lime, gypsum, concrete and aggregates; brick, refractories and tile; preservative coatings; petroleum products and lubricants; road materials; waterproofing and roofing materials; rubber products and insulating materials; textile materials; coal, coke, timber and miscellaneous. The two volumes may be obtained at the following prices: Part I, cloth $7.50; half leather $9.00. Part II, same prices. Both parts at $14.00 and $17.00 according to binding. Address American Society of Testing Materials, 1315 Spruce St., Philadelphia, Pa.

Electrical Definitions

The Sectional Committee on Electrical Definitions of which the Institute is sole sponsor and that is engaged in what is virtually the compilation of a dictionary of American standard definitions in the electrical field, is now reaching a point in its work where results are showing. Certain of the 15 sub-groups to which the work has been allocated are furnishing reports in a status suitable for setting in type for final distribution. The work is slow because of the care with which it must be carried on and the necessity of obtaining approval of all interested bodies.

In their preliminary reports the various chairmen are confining themselves to those definitions on which there is no question. Others will follow later as difficulties are ironed out and inconsistencies eliminated. Those groups which are advanced farthest at present are, illumination, transportation, control and transmission. When the work is completed the publication containing the complete report will be of great value to the electrical industry.

Personal

F. D. Newbury, former manager of the power engineering department of Westinghouse at East Pittsburgh, has been appointed general manager of machinery engineering; R. A. McCarty succeeds him in the power engineering department managership.

T. A. Fawell has made new business connections with the Marwood Company of San Francisco, which operates in six Pacific Coast cities under its various local organizations in its activities of repair and construction of motors and shop equipment.

Claxton A. Allen, formerly manager of the southwestern district of Westinghouse Electric & Manufacturing Company, was elected a commercial vice-president at a recent meeting of the company's board of directors. Mr. Allen's duties of coordination will extend to the domestic appliance division and others serving the household market, including refrigeration, radio, etc.

Everitt W. Wilson, formerly vice-president of R. W. Hebard Co., Inc., of New York, and later foreign representative for the J. G. White Engineering Corporation of New York, now is associated with Winston Brothers Company of Minneapolis, Minn., as representative for the negotiation of contracts outside of the United States.

Obituary

William B. Clarkson, of the industrial control engineering department of the General Electric Company, Schenectady, and since 1919 an Associate of the Institute, died Oct. 23, 1930, at the Long Island City College Hospital, Brooklyn, N. Y., after an illness of several weeks.

He was a native of Brooklyn (December, 1892) and held two professional degrees, A. B. from Williams College in 1913 and M. E. E. from Harvard Graduate School of Engineering in 1915. His professional work with the General Electric Company originated in 1915 when he became test man in the Schenectady works; in 1917 he advanced to the position of engineer of the industrial control department of the same Company. In August of that year he received his commission as a second lieutenant of engineers, assigned to the 303d Engineers as supply officer for the 1st Battalion in British Area. He was discharged from military service in 1919 as a first lieutenant and returned to the industrial control department of the General Electric Company.

Edmund D. McCarthy, president of McCarthy Brothers and Ford of Buffalo, N. Y., died suddenly Dec. 13, 1930, of heart failure.

He had been in the electrical business for more than 35 years and was prominent in the field of electrical contractors and jobbers in the State of New York. His efforts had been principally for the betterment of the electrical industry, serving as general chairman of the Electrical League of the Niagara Frontier, past-president of the Buffalo Electrical Contractors Association, and as a director of numerous companies including the Marine Trust Company, the Iroquois Share Company, and the Buffalo Chamber of Commerce. For many years he was in the New York National Guard, in which he rose to the rank of major. He joined the Institute as Associate in 1896 and also was a member of the Engineering Society of Buffalo and numerous local recreative groups including Buffalo Canoe, Buffalo Athletic, Cherry Hill, and Buffalo Country Club.

Andrew M. Hunt, consulting engineer and past member of the Institute died at Berkeley, California, Dec. 8, 1930, in his 72d year. He was a graduate of the Annapolis Naval Academy and had become prominent in both mechanical and electrical engineering fields. Upon extending his resignation from the navy, Mr. Hunt opened his own offices as consulting engineer in San Francisco, but in 1915 he came to New York to head the firm of Peyton-Hunt Company, Inc. His appointment to the Naval Consulting Board took place in 1917. Mr. Hunt was a member of the American Society of Mechanical Engineers, the American Institute of Consulting Engineers, the American Chemical Society, and numerous other technical bodies.

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the addresses as they now appear on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the Secretary at 33 West 39th St., New York.

All members are urged to notify Institute Headquarters promptly of any changes in mailing or business address, thus relieving the member of needless annoyance and assuring prompt delivery of Institute mail, the accuracy of our mailing records, and the elimination of unnecessary expense for postage and clerical work:

Bates, Putnam A., 117 W. 72nd St., New York, N. Y.
Cromwell, R. C., 1814 Harris Trust Bldg., Chicago, Ill.
Dawson, Leonard L., 98 Looker Ave., Springfield, N. J.
Fielding, Geo. T., General Cable Corp., Graybar Bldg., New York, N. Y.
Hursh, G. E., 345 Lenox Road, Brooklyn, N. Y.
Lieb, Adolph W., N. Y. Edison Co., 393 Seventh Ave., New York, N. Y.

Engineering Index

Engineering Index Service
29 West 39th Street, New York, N. Y.

Selected references to current electrical engineering articles from Engineering Index Service's review of some 1,800 technical periodicals.

All articles indexed are on file in the Engineering Societies Library, which will furnish photoprints of any article at a cost of 25 cents per page or make translations of foreign articles at cost.

ARCS

Carbon. A Geometrical Analysis of Open Carbon Arc Phenomena, W. Cramp and A. P. Jarvis. *Instn. Elec. Engrs.—Jl.* (*Lond.*), vol. 68, no. 406, Oct. 1930, pp. 1301-1312, 11 figs. Behavior of carbon arc with resistance in parallel is developed geometrically and proved experimentally; conditions governing musical arc analysis show that musical arc, in which current oscillates about point on volt-ampere characteristic, is possible but that it is unstable; tendency for arc oscillations to grow until extinction ensues is traced; necessity for introduction of thermal term in equations.

BATTERIES

Storage. Characteristics of Secondary Batteries Under Reduced Atmospheric Pressure, S. Makio. *Electrotech. Soc. Waseda—Jl.* (*Tokyo*), vol. 11, no. 10, Oct. 1930, pp. 359-364, 5 figs. Result of investigation, contrary to Dolezaleck's conclusion, shows that capacity of accumulator is increased under reduced pressure and that this increased capacity is maintained for a while, even after accumulator is brought out in ordinary atmospheric pressure, and then, gradually returns to its normal value in atmospheric pressure with repeated charges and discharges. (In English.)

BOULDER DAM PROJECT

The Boulder Canyon Project. *Eng. and Contracting*, vol. 69, no. 11, Nov. 1930, p. 398. Construction features of $165,000,000 dam and reservoir, irrigation canal, and power development by U. S. Bureau of Reclamation; Hoover dam will be about 727 ft. above foundation rock; power plant capacity will be 1,000,000 or 1,200,000 hp.; All-American canal will be 75 mi. long, and Coachella branch will be 115 mi. long; new town will be located about 6 mi. due west of dam site.

CABLES

High-Tension—Joints. Super-Tension Cable Jointing, J. Riedl and R. S. Dawson. *Elec. Engr. of Australia and New Zealand* (*Melbourne*), vol. 7, no. 6, Sept. 15, 1930, pp. 205-208, 7 figs. Method adopted by Australian Siemens Concern in jointing 33-kv. cable for Municipal Council of Sydney.

Underground. 1920-1930 Report Underground Systems Committee. *Nat. Elec. Light Assn.—Reports of Committees*, for mtg. Sept. 25-27, 1930, 57 pp., 20 figs. Résumé of outstanding accomplishments of Committee for administrative year together with recommendations for future study; complete papers on Underground or Cable Distribution Systems in Outlying Territory, Requirements of Good Cable Training, Preparation of Specifications and Standards, Fault Localization in Distribution Cables, Twenty-Ampere Series Street Lighting Circuits, The Use of Eight-Pole Potheads for Multiplying 100-Ampere Primary-Feeder Cables, etc.

CAPACITORS

The Application and Performance of Series Capacitors, M. I. Alimansky. *Gen. Elec. Rev.*, vol. 33, no. 11, Nov. 1930, pp. 616-625, 17 figs. Function of capacitors; comparison with other regulative equipment; applications for line regulation, for division of load in loop circuits, protection of equipment, analysis of capacitor installation; article is followed by report of sub-committee on series capacitors for voltage regulation in which table is shown of line drop in per cent of receiver voltage when all reactance is neutralized by series of capacitors; also chart useful in transmission-line design.

CIRCUIT BREAKERS

Oil. New Departure in Oil Switch Fuse Design. *Elec. Times* (*Lond.*), vol. 78, no. 2036, Oct. 30, 1930, pp. 751-752, 3 figs. Rotary switch action applied to oil switches secures important advantages and safety of operators.

COMMUTATORS

Electric. Phenomena Connected With the Collection of Current From Commutators and Slip-Rings, H. G. Taylor. *Instn. Elec. Engrs.—Jl.* (*Lond.*), vol. 68, no. 406, Oct. 1930, pp. 1356-1363, 16 figs. Experimental investigation of copper picking, followed by critical survey of existing data, leading to explanation to account for this deposition of metal, and investigation into mechanism of passage of current from slip ring or commutator to brush; variation of contact voltage drop with speed, brush pressure and current is shown. Bibliography.

CONDENSERS

Induction Motor. The Use of Condensers for Operating Single-Phase Induction Motors. *Elec. News* (*Toronto*), vol. 39, no. 12, Nov. 1, 1930, pp. 50-51, 5 figs. Use of condensers for generating artificial rotary field; starting of electric motors for domestic use; systems and connections are shown.

Static. Static Condensers as Phase Compensators (Statische Kondensatoren als Phasenkompensatoren), A. Imhof. *Schweiz. Electrotechnischer Verein* (*Association Suisse des Electriciens*)*—Bul.* (*Zurich*), vol. 21, no. 20, Oct. 22, 1930, pp. 653-666, 12 figs. Construction of condensers for reactive power compensation, economic limits; numerical example in which is shown how power-factor improvement can lead to savings in power cost; economic advantages of static condensers over rotating equipment; space requirements; accessories.

CORONA

Loss Measurements. The Measurement of Corona Losses, F. M. Denton. *Gen. Elec. Rev.*, vol. 33, no. 11, Nov. 1930, p. 615, 2 figs. Current measurements on line were taken with one line grounded; combination with stroboscopic measurements; in addition to measurements such as usually are made on low voltage side of transformer supplying power to line.

EDUCATION

Engineering. Present Trends in Engineering Education, H. Tucker. *Eng. News-Rec.*, vol. 105, no. 21, Nov. 20, 1930, pp. 806-807. Colleges and universities foster multiplication of types of engineers by providing many special vocational courses; vocational aim in engineering education; branches of engineering included in curricula of 71 schools; lack of uniformity; five main divisions of engineering; modern languages in curricula; broader engineering classifications needed.

ELECTRIFICATION

Coal Mines. Modernizing a Large Western Coal Mine with Electricity, R. S. Trowsdale. *Elec. News* (*Toronto*), vol. 39, no. 21, Nov. 1, 1930, pp. 47-49, 5 figs. Crow's Nest Pass Coal Co. in British Columbia, was operated entirely by steam power; in 1928 it was decided to purchase number of large air compressors, and question of economical purchase of power came up for consideration; power supply is from East Kootenay Power Co.; suitable substation provided by power company adjoining compressor station; primary current at 66,000 volts is transformed to 2300 volts for 600 and 400 hp. 3-phase 2300-volt motors.

Copper Mines. Electrification of the Utah Copper Mine, R. Corfield. *Gen. Elec. Rev.*, vol. 33, no. 11, Nov. 1930, pp. 600-607, 14 figs. Reasons why electric shovels and locomotives are used in one of largest mining undertakings in world; comparative shovel costs and comparative shovel characteristics; power input graphs for d-c. and a-c. shovels; electric locomotives; overhead line construction; locomotive data; control room; power transmission; specifications of forms of electric locomotives and shovels.

ELECTRIC DRIVE

Iron and Steel Plants. A Comparison of Alternating-Current and Direct-Current Motors for Auxiliary Drives, G. Fox. *Iron and Steel Engr.*, vol. 7, no. 10, Oct. 1930, pp. 505-511, 7 figs. In planning for expansion of steel industry of U.S.S.R., German consultants, reflecting prevailing German practice recommended use of a-c. auxiliary motors while Americans recommended 230 volt d-c. motors for services of intermittent character where mill-type motors are applicable; as this is question wherein experience and judgment are of greater importance than theoretical considerations, writer addressed questionnaire to 20 members of A.I.S.E.E. soliciting opinions and comment; analysis of questionnaire.

Paper Machinery. Modern Standards in Sectional Paper Machine Drive, R. R. Stoltz. *Paper Trade Jl.*, vol. 91, no. 15, Oct. 9, 1930, pp. 49-51, 7 figs. Automatic speed regulation by field control, moderate-speed geared motor, automatic starting and speed control equipment concentrated in single control board, generator system of starting, inching and slow speed operation, carbon pile voltage regulators individual drive of cylinder moulds and presses on wet end of board machines, carbon pile sectional speed regulator.

Strip Mills. Synchronous Motors for Main-Roll Drive, H. W. Harper. *Elec. Jl.*, vol. 27, no. 11, Nov. 1930, pp. 657-659, 4 figs. With increasing amount of attention now given to power-factor conditions, and notable improvements made in design of synchronous motors, this type of drive merits serious consideration for almost any large or reasonably large constant-speed application.

FURNACES.

Electric Furnaces, V. O. Cutts. *Elec. Rev.* (*Lond.*), vol. 107, no. 2760, Oct. 17, 1930, pp. 617-619, 5 figs. Application to industrial heating, with special reference to resistance type; notes on growing application; continuous-type furnaces; precision in heat treatment; bright annealing; vitrous enameling; high-temperature furnaces; economic considerations; ideal electrical load.

Melting Cast Iron. Using Off-Peak Power for Melting Gray Iron, W. R. Jennings. *Metals and Alloys*, vol. 1, no. 17, Nov. 1930, pp. 814-815, 1 fig. Experiences of Baker-Perkins Co. of Saginaw, in operating rocking type electric furnace on cold stock melting of gray iron; charts illustrate how demand was reduced from 960 kv-a. to 640 kv-a., difference of 320 kva. which represents saving in demand charge of $5500.00 per yr.; using 590 kw-hr. per heat, cost of electrical energy per pound is 0.00295 cent.

Heat Treating. High-Speed Steel Treated in a Special Electric Furnace, E. N. Brookings. *Iron Age*, vol. 126, no. 19, Nov. 6, 1930, pp. 1295-1298, and 1360, 2 figs. Details of construction and operation of electric hardening furnace at plant of Jones and Lamson Machine Co., Springfield, Vt. for treating threading chasers for automatic dies, taps, lathe tools, and miscellaneous parts.

FUSES.

Rupturing Characteristics of High-Tension Fuses. *Elec. World*, vol. 96, no. 19, Nov. 8, 1930, pp. 870-871, 4 figs. Tests conducted for several years by Alabama Power System at short-circuit laboratory constructed for purpose at Bessemer substation; data indicate satisfactory operation at currents up to peak value of over 8500 amperes at 44 kv. and nearly 2000 amperes at 110 kv.

Re-Fusing Switches. Pole-Top Re-Fusing Made Easier, C. L. Lawrie. *Elec. West*, vol. 65, no. 5, Nov. 1, 1930, p. 233, 2 figs. To provide quicker and safer method of re-fusing poletop line switches on its 12-kv. distribution lines without resorting to use of hot-line tools and without killing line, new switching arrangement has been developed by San Diego Consolidated Gas & Electric Co.; system is detailed.

HEATERS

Water. Economic Advantages of Off-Peak Water Heating, L. L. Eden. *Elec. World*, vol. 96, no. 19, Nov. 8, 1930, pp. 863-869, 6 figs. Typical winter and summer loads showing availability of off-peak power; favorable characteristics of off-peak load; comparative cost of on and off-peak water heating; typical load curves of city and suburban a-c. substation for December and June; performance of water heaters at various hours and rates of water usage; comparative cost of fuels for water heating.

HEATING

Domestic. Off-Peak System of Electric Heating for Buildings, E. Harrington. *Heat., Piping and Air Conditioning*, vol. 2, no. 11, Nov. 1930, pp. 963-967, 6 figs. Operating cost of electric heating depends upon number of variables, among which are power rate and characteristics of building to be heated; table illustrates energy used for electrically heating 18 houses, Fort Wayne, Ind.; list of advantages of electric heating; domestic water heating.

HYDRAULIC MACHINERY

Cavitation. Experimental and Theoretical Investigations of Cavitation in Water [Experimentelle und theoretische Untersuchungen ueber Hohlraumbildung (Kavitation) in Wasser], J. Ackeret. *V. D. I. Zeit.* (*Berlin*), vol. 74, no. 9, Mar. 1, 1930, p. 264. Investigation of simple types of flow, such as those round blades, through channels, and past spheres, has been done at Goettingen; it was found that many apparently widely different types of cavitation are of quite common characteristics; investigations show that at core of bubbles shock pressure is sufficient to cause observed breakdown of material.

HYDROELECTRIC POWER PLANTS

Report of Hydraulic Power Committee (Eng. Sec.) presented at 23rd annual mtg. of Pa. Elec. Assn. (Eastern Geographic Div. N.E.L.A.), Bedford Springs, Pa., numerous figs. and tables. Minutes of meetings; manufacturers' statements as to volume and equipment of hydro-electric installations; during past 12 months orders were placed for Smith turbines developing more than 591,000 h.p., including 81,900 h.p. in propeller type units; Flow Measurement and Forecasting at Holtwood, H. W. Lowy. Output Standards for Hydraulic Units, C. W. Watchorn; Keeping Daily Record of Capacity of Hydro Units, R. D. Shaub; Distribution of Runoff and Rainfall in Susquehanna Valley, C. F. Merriam and E. S. Loane; Seiches in Conowingo Pond, R. Taylor and R. E. Turner; Progress in Remodeling York Haven Hydro-Electric Station, A. W. Reid; list of dam failures.

Ice Control. Ice-Trouble Remedies in Hydro-Electric Plants, C. R. Reid. *Power*, vol. 72, no. 19, Nov. 4, 1930, pp. 728-730, 7 figs. How to keep sluice gates, flashboards, rack bars, headgates, penstocks, surge tanks and waterwheels in operating condition in cold climates; use of steam, hot water and electric heating, compressed air, and electric lights are included in suggested methods.

INSULATORS

Testing. Field Testing of Insulators on Overhead Lines, D. Harvey. *Distribution of Electricity* (*Lond.*), vol. 17, no. 2, Oct. 1929, pp. 223-225, 3 figs. Mechanical faults are particularly noticeable among "cap and pin" type of suspension insulator; "Hewlett" type of insulator, in which hardware is interlocked so that porcelain is in compression, appears to give slightly better service than "cap and pin" types; string type insulators for excellent results; authors experience with string type insulators in 88 kv. line. Extracts from lecture recently delivered to Inst. of Engrs. in Tasmania. (To be concluded.)

INTERCONNECTION

Industrial Power Plants. Engineering Aspects of Interchange of Power With the Industrial Plants, B. F. Wood. *Am. Soc. Mech. Engrs.—Advance Paper*, no. 57, for mtg. Dec. 1-5, 1930, 5 pp. Establishment of means and facilities for utilizing massed resources to serve power requirements of individual industries; economical operations can be effected and overhead costs greatly reduced in great many cases where public utility or other steam-generating or hydro power plants find it possible to hook up with large industrial operations; advent of high steam pressures has largely increased these possibilities.

LAMPS

Gas-Filled. Electric Lighting by Gaseous Discharge Tubes, C. C. Paterson. *Engineering (Lond.)*, vol. 130, no. 3381, Oct. 31, 1930, p. 560. Abstract of portion of presidential address before Institution of Electrical Engineers, dealing with gaseous discharge tubes; although so much work has been done on hot cathode tube, many interesting developments of original cold cathode tubes are taking place; under certain conditions, which are only just beginning to be understood discharge instead of filling whole tube, as is normally the case is concentrated into narrow cord only one-fifth of diameter of tube.

Glow. Duration of Emission Phenomena in Glow Lamps (Ueber die Zeit-dauer der Emissionserscheinungen bei Glimmlampen), H. Peters. *Fernsehen (Berlin)*, vol. 1, no. 7, July 1930, pp. 306-310, 2 figs. Quality of picture in television greatly depends on design of glow lamp; investigation of inertia phenomena in this device allows for making conclusions which are of importance in instruction.

Street—Reactors. Investigation of Choke Coils for Parallel Connection to Incandescent Lamps in series for Keeping up of Operation in Case of Burn-out of Lamps (Untersuchung ueber Drosselspulen zur Parellelschaltung mit Gluehlampen, die in Serie geschaltet sind, zur Aufrechthaltung des Betriebes bei Durchbrennen einer oder mehrerer Lampen), I. Ehrenstein. *Elektrotechnik und Maschinenbau (Vienna)*, vol. 48, no. 40, Oct. 5, 1930, pp. 913-915, 5 figs. Performance, characteristics and design data for reactive coils hooked in parallel to lamps in series street lighting for emergency in case of lamp burn-out.

LIGHTING

Industrial. Light and Its Relation to Output, H.C. Wheat. *Machy. (Lond.)*, vol. 37, no. 942, Oct. 30, 1930, p. 135. Relative advantages of various lighting arrangements; good artificial lighting promotes safety, increases production, reduces errors and improves morale of employees; proper use of various types of reflectors; data on light intensities in machine shop. Abstract of paper read before Rugby Eng. Soc.

LIGHTNING ARRESTERS

Lightning Arrester Practise in Southern California, E. R. Stauffacher. *Elec. West*, vol. 65, no. 5, Nov. 1930, pp. 230-231, 5 figs. Instead of following older practise of installing one set of lightning arresters upon each of lines entering and leaving substation, Southern California Edison Co., Ltd., is now following simplified practise of installing lightning arresters only on transformer banks; details of system are given.

MEASUREMENT

Stresses. Use of Telemeters for Measurement of Stresses in Structures (Die Verwendung von Telemetern zu Spannungsmessungen au Bauwerken), F. Treiber. *Bauingenieur (Berlin)*, vol. 11, no. 37, Sept. 12, 1930, pp. 633-636, 14 figs. Description of instrument developed by U. S. Bureau of Standards and report on German tests of this instrument by Probst, at Karlsruhe Institute of Technology.

Electric. Metering Combined Power and Lighting Loads, H. W. King. *Elec. World*, vol. 96, no. 17, Oct. 25, 1930, pp. 774-776, 11 figs. Condition, varying from large power load with small lighting load to large lighting load with small power load, with or without demand with diversity factor included, defeat adoption of one uniform metering scheme for all cases; it is illustrated how some of these conditions may be met and to point out advantages or disadvantages of various combinations which may be used.

Reactive Power. Reactive Kv-a. Metering, E. C. Goodale. *Elec. West*, vol. 65, no. 5, Nov. 1, 1930, p. 232, 2 figs. Cross-phase connections provide required phase relations for reactive kv-a. metering on two-phase circuit. (Continuation of serial.)

MOTORS

Torque. Torque Characteristics of Electric Motors, W. T. Burdick. *Power Transmission*, vol. 37, no. 3, Sept. 1930, pp. 15-17. Common types of direct and alternating-current motors; starting torque, full-load running torque, and maximum torque; table of characteristics and typical applications of motors.

Variable Speed. Multispeed Motors for a Multitude of Uses, R. H. Rogers. *Power Plant Eng.*, vol. 34, no. 22, Nov. 15, 1930, pp. 1289-1292, 5 figs. Two, three and four-speed, speeds available, speed control, and examples of applications.

NETWORKS

Design. Municipalities Gain from Network Distribution, A. Hussey. *Elec. World*, vol. 96, no. 17, Oct. 25, 1930, pp. 770-772, 8 figs. Under present system it is possible to transmit as much power as under old d-c. system in duct space reduced in ratio of 51 to 1; this has been made possible by development of cable capable of operating at 27,000 volts with high degree of dependability, and of automatic protective devices to clear cable or other device in event of failures; as direct result of decreased duct space and increased capacities, number of line manholes and dimensions of these manholes have been reduced.

OSCILLOGRAPHS

Cathode Ray. Cathode-Ray Oscillograph as Precision Measuring Equipment (Der Kathodenoszillograph als Praezisionsmessgeraet), H. Viehmann. *Archiv fuer Elektrotechnik (Berlin)*, vol. 24, no. 3. Sept. 27, 1930, pp. 349-352, 6 figs. Determination of overvoltage and spark-delay time in puncture testing of air required exact values of first mentioned; it is investigated whether cathode-ray oscillograph is suitable equipment for this purpose.

PHOTOELECTRIC CELLS

Photo-electric Cells, T. T. Baker. *Elec. Rev. (Lond.)*, vol. 107, no. 2762, Oct. 31, 1930, pp. 722-723, 5 figs. Some industrial applications; effect of voltage on output for vacuum cell and gasfilled cell; effect of gas-pressure on output; photoelectric cell circuits. (To be concluded).

POWER SUPPLY

Rural. The National Rural Electric Project and the Agricultural Problem, G. W. Kable. *Baltimore Engr.*, vol. 5 no. 7, Oct. 1930, pp. 4-8 and 24, 7 figs. Aim of project is to improve living conditions and income on American farms, to lessen fatigue and to increase leisure time of farm homemakers, and to ascertain truth concerning economic use of electricity on farm; work consists of practical demonstration of possible uses of electricity on farms, together with investigation and research in application of electricity to agriculture.

Present Status of Research in Rural Electrification, G. W. Kable. *Nat. Elec. Light Assn.—Bul.*, vol. 17, no. 11, Nov. 1930, pp. 693-695, 1 fig. Electrification of agriculture is not problem in motorizing of industry; farming bristles with problems in chemistry, physics, biology, bacteriology, economics and sociology, all of which may be influenced to degree through application of electricity.

PUBLIC UTILITIES

Legislation. Some Influences on Public Utility Legislation, A. F. Tegen. *Nat. Elec. Light Assn.—Bul.*, vol. 17, no. 11, Nov. 1930, pp. 682-685, 8 figs. Net earnings of electric utilities are not excessive when considered in relation to other businesses; if this industry is to maintain its position with respect to its ability to obtain money for improvements, conditions under which it is operating should not be disturbed; analysis of municipal and private utility operation in Wisconsin reveal that whereas municipal utilities started with more revenue per kw-hr. they ended with less.

RADIO

Screen Grid Amplifiers. Application of Screen Grid Tubes to Audio Frequency Amplifiers, J. J. Glauber. *Radio Eng.*, vol. 10, no. 2, Feb. 1930, pp. 29-32 and (discussion) 32-33, 10 figs. Construction of proper circuits suitable to characteristics of typical screen-grid tube. Paper presented before Radio Club of America.

Communication Aerial. Radio for Aircraft. *West. Flying*, vol. 8, no. 5, Nov. 1930, pp. 40-41, 1 fig. Review of recent progress with particular regard to new Department of Commerce regulations governing aircraft radio equipment; effective Dec. 31; advantages of two-way radio phone communication.

Ultra Short Wave. Practical Experiments in Ultra-Short Wave Communication, C. C. Whitehead. *Experimental Wireless (Lond.)*, vol. 7, no. 86, Nov. 1930, pp. 612-620, 11 figs. Range tests and propagation; screening of envelopes of valves, asymmetry of circuit; estimation of transmitter efficiency, effect of time of transit of electrons constituting space-current, constructional details of transmitter and constructional details of receiver, are given in appendix. Bibliography. (Concluded.)

Developments in Ultra-High Frequency Generation, C. W. Loeber. *Electronics*, vol. 1, no. 8, Nov. 1930, p. 376, 2 figs. Barkhausen-Kurz effect was produced with triode with strong positive voltage on grid; voltages determined frequency; wavelength was measured by moving crystal detector along Lecher wires; Gill and Morrell's oscillating circuit in which frequency could be varied by telescoping tubes.

RAILROADS

Electrification—United States. N.E.L.A. Electrification Report. *Ry. Age*, vol. 89, no. 19, Nov. 8, 1930, pp. 974-979, 6 figs. Study of installations on western railroads has developed much useful information concerning operation and maintenance.

Operation. Scheduled Speed Increased by Electrification. *Elec. Ry. Jl.*, vol. 74, no. 12, Nov. 1930, pp. 683-684, 2 figs. Rapid acceleration and braking rates of new electric trains have enabled Lackawanna Railroad to reduce running time by approximately 25 per cent between Hoboken and stations in suburban zone; free running speed also higher than that of steam trains formerly operated.

Substations. The Design and Operation of the Windsor, Essex and Lake Shore Railway Automatic Substations, H. V. Armstrong. *Elec. News (Toronto)*, vol. 39, no. 21, Nov. 1, 1930, pp. 31-34, 5 figs. Diagram of automatic switching equipment for synchronous converters in railway service; sequence of operation; 26.4 kv. switching equipment of notes on operation of 36 mi. line connecting Windsor to Leamington and running through Maidstone, Essex, Cottam, Ruthven and Kingsville, serving county of Essex.

Terminal Electrification. Overhead System of Cleveland Terminal Electrification, L. W. Birch. *Elec. Traction*, vol. 26, no. 10, Oct. 1930, pp. 535-537, 3 figs. Review of electrified terminal stations; 3000 volts d-c. decided upon; insulation details of overhead.

REACTORS

Design. Current-Limiting Reactors, A. H. v. Altmann. *AEG Progress (Berlin)*, vol. 6, no. 11, Nov. 1930, pp. 341-345, 7 figs. Calculation and effects of short-circuit currents; impedance calculation of short-circuit path; thermal and dynamic effects of short-circuit current; construction and installation of current-limiting reactors.

RECTIFIERS

High-Tension. Generation of High-Tension Direct Current from Three-Phase A.C. Current (Die Erzeugung von hochgespanntem Gleichstrom aus Drehstrom), W. Deutsch and W. Hoss. *Elektrotechnische Zeit. (Berlin)*, vol. 51, no. 43, Oct. 23, 1930, pp. 1480-1483, 18 figs. Construction, performance and application of novel mechanical high-tension rectifier by which it is possible to obtain d.c. of voltage approximately equal to maximum value of transformer voltage.

RELAYS

Protective. D.-C. Undervoltage Relay Controls A-C. Circuits, W. M. Brainard. *Power*, vol. 72, no. 19, Nov. 4, 1930, pp. 725-727, 5 figs. Inductor-type d-c. time-delay undervoltage release has been developed that is applied through copper-oxide rectifier to protect a-c. equipment against voltage failures; applications diagrams of inductor-type time-delay device.

TELEVISION

History. Historical Development of Television (Die Geschichtliche Entwicklung des Fernsehens), W. Friedel. *Fernsehen (Berlin)*, vol. 1, no. 1, Jan. 1930, pp. 12-17, 5 figs. General notes on development from 1875 to present.

Life Size. Life Size Television on the Screen (Fernsehen in Lebensgroesse auf der Leinwand), A. Neuburger. *Fernsehen (Berlin)*, vol. 1, no. 10, Oct. 1930, pp. 460-463, 3 figs. Successful transmission by Dr. Alexanderson of picture and voice of living persons and actors over distance of some miles on 10 by 11 ft. screen in 2500 persons theater in Schenectady; equipment is illustrated.

TRANSMISSION LINES

Construction. The Stringing and Sagging of Overhead Line Conductors, H. W. Settle. *Elec. Engr. of Australia and New Zealand (Melbourne)*, pp. 209-213, 5 figs. Practical methods for overhead transmission lines and of tensioning them to correct sag, particularly in rough country; several methods of sagging are given, some involving use of theodolite; wave method, in which sag is determined from speed of travel along wire of mechanically produced wave.

Gounding. Further consideration is Needed on Grounds and Ground Testing, W. B. Buchanan. *Elec. Canada (Toronto)*, vol. 2, no. 9, Sept. 1930, pp. 22-24 and 34, 1 fig. Subject is outlined so that various views presented may appear in proper relation to entire subject and less contradictory to one another than they occasionally have done.

Protection. Summation Transformer Gives Overcurrent Protection, R. E. Cordray. *Elec. World*, vol. 96, no. 19, Nov. 8, 1930, p. 872, 2 figs. To raise ampere setting of overcurrent relays automatically on two parallel lines when one of lines is temporarily out of service for any reason, New England Power Co. adopted novel arrangement by bridging auto-transformer by overcurrent relay and connecting midtap to common connection of cross-connected current transformers.

Theory. Transmission of High-Frequency Oscillating Electric Power (Die Fortleitung hochfrequenter elektrischer Schwingungsenergie), H. O. Roosenstein. *Zeit. fuer Hochfrequenztechnik (Frankfort)*, vol. 36, no. 4, Oct. 1930, pp. 121-123, 17 figs. Data of lines applied in practise; wave resistances, damping, numerical example; theory of damping measurements; observation of safety in measurements, etc.; asymmetry of two wire lines; experiments, removal of line asymmetry.

TRANSMISSION LINES, HIGH TENSION

Design. Transmission Tower Design for Maximum Lightning Protection, Fortescue. *Elec. Jl.*, vol. 27, no. 11, Nov. 1930, pp. 640-644, 8 figs. Calculated results for tower of horizontal construction with transmission lines 76 ft. above surface of earth and ground wires in vertical plane 25 ft. above line wires is given; from curves can be determined necessary length of insulator string to withstand surge potential due to lightning stroke on ground wire or value to which tower-footing surge impedance must be reduced in order to prevent flashover of given length of string.

Protection. Protection from Surges, E. T. Norris. *Elecn. (Lond.)*, vol. 105, no. 2734, Oct. 24, 1930, pp. 496-497, 3 figs. Safeguarding of apparatus against lightning and other surges; discharge arresters giving place to surge absorbers.

Theory and Application of Relay Systems, P. H. Robinson and I. T. Monseth. *Elec. Jl.*, vol. 27, no. 11, Nov. 1930, pp. 660-668, 37 figs. Notes on apparatus protective relays; equipment is illustrated; characteristic curves are given. (Continuation of serial.)

TRANSFORMERS

Current. Factors in Connecting Secondaries of Current Transformers, J. Auchincloss. *South Power Jl.*, vol. 48, no. 11, Nov. 1930, pp. 51-53, 4 figs. When current transformer secondaries should be connected in series and when in parallel, and effect of each connection on division secondary burden; analysis of problem.

Oil-Immersed Current Transformers, I. H. Sclater. *Gen. Elec. Rev.*, vol. 33, no. 11, Nov. 1930, pp. 658-659, 6 figs. New types of oil immersed current transformers and described under headings; accuracy; connections; bushings tanks; by-pass protectors.

TURBO-GENERATOR

Rotors. Stresses in Retaining and Centering Rings for Turbine-Generator Rotors, R. Patterson and D. H. Harms. *Am. Soc. Mech. Engrs.—Advance Paper*, no. 42, for mtg. Dec. 1-5, 1930. 9 pp., 8 figs. Distribution of stresses throughout system of parts enclosing rotor coil ends of turbine generator; system consists of disk of uniform cross-section cylinder, and part of shaft; summary of significant results.

VACUUM TUBES

Filaments. The Role of Barium in Vacuum Tubes, J. A. Becker. *Electronics*, vol. 1, no. 8, Nov. 1930, pp. 390-391, 2 figs. It is shown how ionic barium grid accounts for many of observed emission characteristics of coated filaments; for all thousands of tubes in use in Bell System total amount of effective barium is not more than twentieth of gram; each barium-coated filament requires only about 2.2 watts for heating as compared to about 35 for clean tungsten filament; multiplying this saving by 250,000 tubes used in Bell System gives indication of tremendous importance of barium to vacuum tubes.

Oscillators. The Effect of Combined A.C. and D.C. Plate Supply on a Short Wave Triode Oscillator, G. S. Field. *Can. Jl. Research (Ottawa)*, vol. 3, no. 4, Oct. 1930, pp. 287-290, 3 figs. By combining a.c. and d.c. on plate of triode oscillator, more stable and much stronger oscillations were obtained than with pure d.c.; increases in radio frequency current up to 2.5 times were noted; experiments with 200-cycle and 60-cycle a-c. showed that higher frequency gave stronger oscillations.

Rectifier. Vacuum-Tube Rectifiers Control Motor Speed, W. R. King.

Power, vol. 72, no. 20, Nov. 11, 1930, pp. 761-763, 6 figs. Operation of thyratron, mercury-arc rectifier with grid control, and its application to control speed of d-c. motors supplied by a-c. circuits; diagram of single-phase full-wave grid-controlled thyratron rectifier.

WATER POWER

United States. Federal Relations to Water-Power Development, F. E. Bonner. *Am. Soc. Mech. Engr.—Advance Paper*, no. 8, for mtg. Dec. 1-5, 1930, 3 pp. Survey of part played by Federal Government; Federal jurisdiction over navigable streams; purpose of Federal Water-Power Act; activities of Federal Power Commission; aggregate capacity of water power plants under license.

WELDING

Arc. Application of Electric Arc Welding to Building and Machine Construction, J. M. Hipple and G. D. Fish. *Eng. and Finance*, vol. 23, nos. 4 and 5, Oct. 1930, pp. 111-112, and Nov., pp. 145 and 158, 8 figs. Abstract of paper presented before Inst. Congress of Steel Construction, Belgium, and previously indexed from Welding Engr., Sept. 1930. (To be continued.)

Arc—Atomic Hydrogen. Welding with Atomic Hydrogen Process, S. Martin, Jr. *Welding*, vol. 1, no. 13, Nov. 1930, pp. 907-909 and 912, 7 figs. Fundamental principles and electric equipment; connection diagram for atomic-hydrogen arc-welding equipment; graph illustrates tungsten electrode consumption, average welding speed, and average welding curve for steel plates.

Buildings, Steel. Welding a 14-Story Building, J. L. Faden. *Elec. World*, vol. 96, no. 18, Nov. 1, 1930, pp. 824-829, 10 figs. Details of electric welding of two Boston Edison Co.'s buildings; nearly mile of electric welds, consuming 6120-kw-hr.; 1054 tons of steel welded; average inches of weld per man per hr. 47.4; operators selected to qualify for this important undertaking; building welds specified in detail; advantages of welding; summary of welding inspection reports; welding data; details of welded steel frames.

Pipe, Ste l. Electrically welded Steel Water Pipe, W. H. Powell. *Can. Engr. (Toronto)*, vol. 59, no. 19, Nov. 1930, pp. 599-604, 5 figs. Description of methods used in making and testing of 50,000 ft. of pipe in British Columbia for Greater Vancouver water district's system; butt-weld and lap-weld tests; fitting pipe sections; cleaning and dipping; manufacturing pipe bends; hand-weld and machine-weld tests; hydrostatic test; pipe diameters varied from 26 to 36 in.

X-RAY APPARATUS

The Development of Modern X-Ray Generating Apparatus, W. D. Coolidge. *Gen. Elec. Rev.*, vol. 33, no. 11, Nov. 1930, pp. 608-614, 18 figs. Early type of tube by Roentgen; Jackson's first tube employing focused cathode rays; development of ductile tungsten; tungsten target; manufacture of photomicrograph of crystalline structure of tungsten before and after swaging; hot-cathode tube; types of tubes; heat removal from focal spot; 500,000-volt X-ray tube built in two sections; tubes for very high-voltage X-ray therapy. Abstract of lecture before Am. Roentgen Roy. Soc., Sept. 24, 1930. (To be continued.)

New Books

Available at the Engineering Societies Library

ENGINEERING SOCIETIES LIBRARY
29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

NEW BOOKS AVAILABLE NOVEMBER 1-30, 1930

UNLESS otherwise specified, these books have been presented by the publishers; the Institute assumes no responsibility, all statements being taken from the preface or the text of the book.

A. S. T. M. TENTATIVE STANDARDS, 1930. By American Society for Testing Materials. Philadelphia, The Society, 1930. 864 pp., illus., diagrs., tables, 9 x 6 in., paper. $7.00; cloth, $8.00.——This new edition contains 155 specifications, methods of testing, etc., that have not yet been adopted finally by the Society as standards, but are under consideration, and are offered for criticism. They cover the whole field of engineering materials, there being specifications for various metals, cement, clay products, preservative coatings, road materials, insulating materials, coal and coke, and various other substances.

COMMERCIAL A-C. MEASUREMENTS. By G. W. Stubbings. N. Y., D. Van Nostrand Co., 1930. 325 pp., diagrs., 9 x 6 in., cloth, $6.00.——This book aims to occupy a position between the descriptive treatise and the handbook of test methods. The author omits details of the construction of instruments and confines descriptive matter to that necessary to elucidate the principles of methods, using the space gained for a fairly exhaustive presentation of the theory and practise of the measurement of current, voltage, power, energy, and power factor. Three-phase measurements are treated rather fully. A chapter is devoted to test-room equipment. The work is intended for testing engineers.

GOETHALS, GENIUS OF THE PANAMA CANAL; a Biography. By Joseph Bucklin Bishop and Farnham Bishop. N. Y. and Lond., Harper & Bros., 1930. 493 pp., illus., ports., 10 x 6 in., cloth. $5.00.——A vivid and interesting account of General Goethal's career covers his various activities at West Point, as an army engineer, at the head of the Panama Canal work, and in later life. The work is based on intimate acquaintance and access to many private sources of information, the senior author having been secretary of the Isthmian Canal Commission.

INTRODUCTION TO SURFACE CHEMISTRY. By Eric Keightley Rideal. 2nd edition. Cambridge, Eng., University Press; N. Y., Macmillan Co., 1930. 459 pp., diagrs., tables, 9 x 6 in., cloth. $6.00.——The rapid growth in the study and industrial use of colloidal systems makes desirable an adequate understanding of the properties of surfaces and interfaces. This book aims to review our present knowledge of interfacial systems, in a volume of reasonable size. Students of colloids will find it a valuable introduction to the subject.

KRAFTWERKS-BAUTEN. [2nd edition]. Berlin, Siemens-Schuckert, [Published by V. D. I. Verlag, 1930]. 138 pp., plates, 12 x 8 in., bound. 6. r. m.——A volume of photographs and plans of a number of electric power plants recently built by the Siemens-Schuckert works. The layout and construction of the buildings are considered, not the equipment. Brief data about capacity and equipment are given, with references to more comprehensive published description.

REGELN FÜR ABNAHMEVERSUCHE AN WASSERKRAFTMASCHINEN. 2d edition. Berlin, V. D. I. Verlag, 1930. 8 pp., illus., 12 x 8 in., paper. 1,50 r. m.——These rules for acceptance tests of hydraulic turbines have been formulated by a joint committee of the German associations of engineers and hydraulic interests, with the cooperation of Austrian and Swiss societies. The present revision corresponds to the standards of the International Electrotechnical Commission.

THE SELENIUM CELL; its Properties and Applications. By George P. Barnard. N. Y., Richard R. Smith, Inc., 1930. 331 pp., illus., diagrams, 10 x 6 in., cloth, $9.00.——This valuable monograph aims to present a precise, accurate survey of our knowledge of the properties of selenium and of the applications of selenium cells to photophony, television, talking films and other practical uses. The scattered literature has been very thoroughly summarized and an exhaustive bibliography is included in the book, which will be found most useful by all workers in this field.

STATISTIK FÜR DAS JAHR 1929. By Vereinigung der Elektrizitätswerke. Dortmund, W. Crüwell, 1930. 687 pp., map, 12 x 9 in., boards. 50.-r. m.——An elaborate statistical analysis of the electricity supply of Germany, with data also for a number of power plants in neighboring countries. The data for each plant are very complete and include the information usually wanted as to sources of power, size, efficiency, rates, methods of distribution, equipment, etc.

TABLES ANNUELLES DE CONSTANTES ET DONNÉES NUMÉRIQUES. TABLE DES MATIERES, v. 1-5; 1910-1922. Paris, Gauthier-Villars et cie., N. Y. McGraw-Hill Book Co., 1930. 382 pp., 11 x 9 in., cloth. $20.00——The appearance of this index will be welcomed by all users of the Annual Tables of Constants. It contains analytic, alphabetic, and formula indexes to the material in the first five volumes of the tables, thus making it a simple matter to find what is wanted, and making the set much more useful than it has been.

Local Meetings

Group Activities—What Do They Mean?

When a national organization such as the American Institute of Electrical Engineers is established in a field just coming into being as it was in 1884, its progress over a period of a few years is often phenomenal. The men who had the initiative, spirit and willingness to make the start remain with their shoulders to the wheel, and their enthusiasm is contagious; it spreads without effort, and new members flow into the organization without the necessity of a membership campaign. And, the entire field being of small compass, all are familiar with its various phases, a common interest providing the incentive which keeps the wheels turning.

Years elapse, and the organization grows geographically to become national, and even world-wide. The electrical field is now one of the most complex of its kind, its branches extending from most profound pure science through all the scope of applied sciences. No longer is an all-embracing group possible nor can any one individual master the entire field. Geographical segregation and technical specialization have of necessity crept in and are increasing with time. Groups of men within the big family circle now have interests separate and distinct from those of another division in the field, making for a tendency to break away—to form independent organizations, each devoted to its own local interests and its own specialty.

To take care of this from the geographical standpoint and counteract so far as possible the disadvantage of the hundreds—and even thousands—of miles intervening between centers of activity, the Institute in 1902 approved a plan for the organization of "Sections" in these electrical centers; also for the grouping of engineering students into "Branches" in the universities and technical schools. The step resulted in an immediate rise of the membership curve. In 1919 further effort to give each member opportunity to play his individual part in the progress of the Institute, and to profit by its activities, was evidenced by dividing the country into "Districts" and with a vice-president for each District. Innovations during the following years created various coordinating committees within the Districts and made provision for the payment of certain traveling expenses of delegates. Thus the geographical segregations of the organization knit themselves together. As for the specialization tendency—it, too, has continued to develop, and just so far as conditions would warrant, effort has been made to provide each technical group with papers, sessions, and even meetings, devoted to its specific interests. There was, however, and is, a very definite limit to which this could be carried in time, number of meetings, and finances. Consequently, especially with the larger Sections, lack of interest became evident, and without almost unwarranted effort, good attendance at meetings was difficult to obtain unless meetings included subjects of highly controversial interest or were addressed by effective speakers of national prominence.

Into the picture at this point came the suggestion of "Groups" within the Sections. Chicago and New York immediately put such division into action, New York organizing four groups—Power, Transportation, Communication, and Illumination. So far as possible, execution of plans was placed in the hands of the younger men, who were also expected to provide most of the papers for their group meetings. Free and open discussion at all meetings was encouraged and as expected, the younger men who had never previously been heard at the larger meetings proved eager to prepare papers and take active part in the discussions.

In presenting Group subjects, the effort is always to present a picture comprehensible to those outside a particular field of activity, encouraging the attendance of other groups and broadening the interest. Attendance at Group meetings in New York has frequently equalled, or even exceeded, that formerly registered at general, monthly meetings. But as they appear to be entirely feasible the monthly meetings have continued and there is a strong desire to make such meetings of the widest general interest.

But what has resulted from two years of Group activity? Speaking from the New York point of view—and probably the same applies to Chicago—there has been awakened interest in Section activities. In a city where there are almost endless counter attractions, meeting attendance has increased and is continuing to increase. Men who appeared to have actually passed outside Institute portals have not only come back, but have done so actively, since it is now possible to find here material which they were compelled to acquire elsewhere. The younger man who felt that he had no place in the internal workings of the Institute and who often queried "What do I get out of it?" now feels, and rightly, that he has a new and very real part to play. The New York Section activities have resulted in a greatly increased rate of membership, and have incited men already members to seek advancement to the higher grades, all of which demonstrates a healthy awakening of interest.

The Group movement has apparently solved the tendency to divide and is perhaps the first step toward consolidation.

◆

N. Y. Section Groups to Hold Joint Meeting

Railroad power supply has aroused such wide general interest that the New York Section has arranged a joint meeting of its Transportation and Power Groups to be held on the evening of January 9, 1931. Two papers will be presented:

Power Supply for the D. L. & W. Electrification, by R. D. Booth of Jackson & Moreland, and

Some Business Aspects of Railroad Power Supply, by A. E. Banham of the Public Servic Electric & Gas Company.

Ample time will be allowed for discussion, and anyone interested is cordially invited to participate, even though he may not be affiliated with the New York Section.

The meeting will be held at 7:30 p. m. in Room 1, Engineering Societies Building, 33 West 39th Street, New York, N. Y.

Student Activities an Integral Part of Recent Louisville District Meeting

As parts of the Southern District Meeting in Louisville, Ky., November 19-21, 1930, a student technical session, a conference on student activities, and a luncheon for counselors, chairmen, and other faculty members and students were held.

Technical Session

Professor D. C. Jackson, Jr., chairman, Committee on Student Activities, District No. 4, presided at the student technical session on Thursday morning, which was opened by two brief addresses as follows:

Welcome for the A. I. E. E.
Professor W. S. Rodman, Vice-President, A. I. E. E.

Student Technical Sessions
H. H. Henline, Assistant National Secretary, A. I. E. E.

Mr. Jackson announced that first, second, and third prizes of $25, $15, and $10, respectively, would be awarded by the three judges, Vice-President Rodman, and Messrs. F. M. Craft of Atlanta, and F. H. Miller of Louisville, at the conclusion of the following program presented by students:

The Romance of Television
L. C. Vipond, North Carolina State College of A. & E.

George Westinghouse—A Brief Review of His Life and Career
J. M. Leigh, Mississippi A. & M. College

Theory and Operation of "Deion Grid" Oil Circuit Breakers
Herbert L. Stokes, University of South Carolina

Cooperative Education
John G. Lips, University of Louisville

Student Branch Activities
Russell Ranson, Duke University

Duct-Line and Manhole Construction for Underground Distribution Systems
P. C. Stoll, Georgia School of Technology

An Engineer's Gift to the Invalid
T. C. Brown, University of Kentucky

Lightning Study on Martin Dam-Leeds 110-kv. Transmission Lines
J. C. Evans and H. B. Hendrix, University of Alabama (Presented by Mr. Evans)

Luncheon

The University of Louisville gave a luncheon on Thursday for all counselors, Branch chairmen, and other faculty members and students attending the District Meeting. Professor S. T. Fife, Head of the Electrical and Mechanical Engineering Dept., presided, and Dean B. M. Brigman gave the address of welcome.

In a most interesting and inspiring address, W. S. Lee, president of the A. I. E. E., discussed the great importance of the development of young engineers through the most beneficial kinds of education and practical experience. He then explained in detail some aspects of large engineering construction projects with which he has been connected.

Vice-president Rodman announced the awards for the presentation of student papers at the morning session, and presented prizes as follows:

First: $25, P. C. Stoll, Georgia School of Technology

Second: $15, J. G. Lips, University of Louisville

Third: $10, H. L. Stokes, University of South Carolina

Conference on Student Activities

Professor D. C. Jackson, Jr., chairman of the District Committee on Student Activities, presided at the Conference on Student Activities held Thursday afternoon. As District counselor delegate to the Summer Convention at Toronto, he reported upon the recommendations adopted at the Conference of Officers, Delegates, and Members. He called attention to the parts of the 1930 report on Section and Branch Activities which are of particular interest to Branch officers.

The University of Florida was chosen as the location of the District Conference on Student Activities in 1931, and the consensus of opinion was that it should be held in the Fall Semester.

Professor Joseph Weil, counselor of the University of Florida Branch, was elected chairman of the District Committee on Student Activities, to take office immediately, and also counselor delegate to the Summer Convention in Asheville in June 1931.

Some of the other topics discussed are given below:

Most effective types of programs.
Improvement of attendance at Branch meetings.
Advisability of electric shows by students.
Training next year's officers of Student Branches.
Requirement of personal presentation of papers at Student Technical Sessions.
Aid from the A. I. E. E. in financing research work by students.
Financing the office expenses of the chairman of Student Activities Committee.

A vote of thanks was extended to Professor Jackson for his admirable work as chairman of the District Committee on Student Activities.

Future Section Meetings

Cleveland

January 22, 1931—Future Power Development and Distribution in the Cleveland Metropolitan Area, by H. L. Wallau, Chief Electrical Engineer, Cleveland Electric Illuminating Co.

February 19, 1931—Recent Progress in Communication Technology. Speaker from the Bell Telephone Laboratories, Inc., to be announced later.

Detroit-Ann Arbor

January 20, 1931—Underground Cables, by G. B. McCabe, Detroit Edison Co., and L. F. Hickernell, Allied Engineers, Inc. Meeting at Detroit Edison Auditorium.

February 17, 1931—Detroit Toll Board, by E. C. Balch, Michigan Bell Telephone Co. Meeting at Michigan Bell Telephone Auditorium.

Niagara Frontier

January 16, 1931—Dean Kimball, Cornell University, will speak on Industrial Economics or similar subject.

February 16, 1931—Air Circuit Breakers, by Mr. Gunion, I. T. E. Company.

Seattle

January 20, 1931—Meeting on Communication Engineering by an engineer from the headquarters staff of the Bell Telephone Co.

February 17, 1931—Operating Problems of Trunk Line Electrification, by J. Hawe, Electrical Engineer, Great Northern Railway.

Spokane

January 23, 1931—Predetermination of Transient Stability, by H. V. Carpenter, Dean, College of Mechanic Arts and Engineering, State College of Washington.

Past Section Meetings

Akron

Inspection trip to the electrification and signal system of the Cleveland Union Terminal. Address by H. W. Pinkerton on the electrical and mechanical features of the project, illustrated with films and slides. November 15. Attendance 50.

Atlanta

Inspection trip through the Plant Atkinson Steam Station of the Georgia Power Co. After a buffet supper, provided by that Company, short talks were given as follows:

Georgia Power Company in the Industrial Structure of the State, by W. E. Mitchell, Vice-President, Georgia Power Co.;

Design of Plant Atkinson, by W. P. Hammond, Allied Engineers, Inc.;

Plant Atkinson on the Line, by J. M. Oliver, Georgia Power Co. Joint meeting with the A. S. M. E., attended by students from the Georgia School of Technology. November 24. Attendance 325.

Baltimore

Engineering and Unemployment, by E. C. Stone, Duquesne Light Co., and Vice-President District No. 2, A. I. E. E. Dinner in honor of the speaker preceded the meeting. November 21. Attendance 27.

Boston

Louisiana Power Station of the Louisiana Steam Products, Inc., by Messrs. Weterer, C. R. Stewart, W. L. Locke, and H. J. Klotz. All the speakers are affiliated with Stone & Webster, Inc., and each told of the problems and special features of design that he encountered building this station in the record time of six and one-half months. November 18. Attendance 160.

Cincinnati

The Design and Characteristics of Induction Motors, by Mr. Carter, Allis Chalmers Mfg. Co. This talk included analysis of various designs and examples of their application in industry. General discussion followed. Dinner preceded the meeting. October 9. Attendance 53.

The Use of Electric Industrial Trucks, by C. B. Crockett, Industrial Truck Association. M. R. Berry, Electric Products Co., discussed truck batteries and charging methods. Three reels of motion pictures of electric truck application in large industries were shown. Following the talks, there was considerable discussion on such subjects as truck sizes, maintenance costs, power requirements, battery life, etc. Dinner in honor of the speakers preceded the meeting. November 13. Attendance 80.

Cleveland

High-Voltage Phenomena, by A. O. Austin, Ohio Insulator Co. Preceding this talk, Mr. Austin gave a series of demonstrations of artificial lightning, which he explained in some detail. E. L. Cove, Chief Engineer of Station WHK, gave a short talk on the advisability of insulating radio towers. He explained the advantages of such insulation and described the tests that were being conducted between Station WHK and Station WABC. October 16. Attendance 191.

The Electrical Features of the New Cleveland Terminal, by H. W. Pinkerton, Cleveland Union Terminals Co. Illustrated with slides and motion pictures. H. G. Leavell, Cleveland Electrical League, demonstrated the various lighting effects which can be obtained in their new auditorium. F. W. Braund, Chairman, gave a short résumé of the Summer Convention at Toronto last June. November 20. Attendance 160.

Connecticut

The Electrical Industry and Electrical Engineering in Russia, by A. Dovjikov, Westinghouse Electric & Mfg. Co. Meeting held at Dunham Laboratory, Yale University. November 11. Attendance 100.

Denver

Aerial Tramways, by Fred C. Carstarphen, Consulting Engineer, illustrated by lantern slides and moving pictures. November 21. Attendance 30.

Detroit-Ann Arbor

Lightning Investigations, by H. P. Seeyle, Detroit Edison Co., and J. R. Eaton, Consumers Power Co. Illustrated with slides. Discussion followed. November 18. Attendance 250.

Erie

Annual banquet and ladies' night. Lights of Home, by Ralph W. Shenton. Short address by E. C. Stone, Vice-President, District No. 2, A. I. E. E. Nate Harrington acted as stunt master. Members of the Technical Federation of Erie attended. November 18. Attendance 120.

Fort Wayne

Conduction, Convection, and Radiation of Heat in Electrical Machinery, by Professor A. D. Moore, University of Michigan. November 20. Attendance 100.

Houston

The Aid of the Automatic Telephone in Power Dispatching, by W. B. Hardin, Southwestern Bell Telephone Co. P. N. Underwood outlined the progress made in power transmission over a number of years. Following the the above talks those present visited the dispatching room of the above company, where the system was thoroughly explained and demonstrated. November 25. Attendance 30.

Indianapolis-Lafayette

Moving the Indiana Bell Telephone Company's Headquarters Building, by Vance Oathout, Indiana Bell Telephone Co.;

Latest Developments in Television, by Professor R. H. George, Purdue University. Also two films presented as follows: "Blasting the Water Highways of America," and "Hydroelectric Developments in the New South." Joint meeting with the Indiana Section of the American Radio Relay League. Dinner preceded the meeting. November 29. Attendance 105.

Los Angeles

F. E. Weymouth, Metropolitan Water District, gave an illustrated lecture concerning the proposed routes for the aqueduct through which the supply of water for Southern California from the Colorado River is to be effected. General discussion followed. Joint meeting with the A. S. C. E., the A. S. M. E., and A. I. M. E. November 12. Attendance 402.

Louisville

Meeting held to discuss plans for the District Meeting at Louisville. November 12. Attendance 40.

Memphis

The Electrification of Dredges, by C. T. Pearce, Westinghouse Elec. & Mfg. Co. R. H. Maxwell, of the same company, demonstrated the Grid-Glow Tube, Photoelectric Cell, and accessory equipment. November 12. Attendance 35.

Mexico

Annual banquet at which the officers for the year 1930-1931 were announced and introduced. November 22. Attendance 53.

Nebraska

Modern Practise of Laying Underground Long Distance Cables, by F. J. Rupe, Northwestern Bell Telephone Co., illustrated with moving pictures showing construction work in progress. November 21. Attendance 40.

Niagara Frontier

Mercury Arc Rectifiers, by Othmar K. Marti, American Brown Boveri Co., illustrated with slides. Motion pictures describing the mining, smelting, refining and rolling of the metal were presented. November 21. Attendance 60.

Oklahoma City

The World Power Conference at Berlin, Germany, by Dean P. S. Donnell, Oklahoma A. & M. College, illustrated with a number of slides made from pictures taken while visiting Europe. Film—"The New Hydroelectric Generating Station at Louisville, Ky." October 30. Attendance 115.

Illumination, by A. E. Warner, Oklahoma Gas & Electric Co.;

The Installation and Operation of Underground Toll Cable, by M. L. Olsen, Southwestern Bell Telephone Co. Illustrated with four films showing the actual installation of several underground toll cables in the southwest. November 24. Attendance 82.

Philadelphia

Some Recent Research Developments, by E. L. Manning, General Electric Co. November 10. Attendance 200.

Pittsburgh

Modern Physics, by Saul Dushman, General Electric Co. Moving pictures preceded the presentation of this paper. Joint meeting with the Engineers' Society of Western Pennsylvania. November 12. Attendance 324.

Pittsfield

Recent Developments in Steam Turbines, by H. L. Wirt, General Electric Co. Illustrated with slides. Dinner preceded the lecture. November 18. Attendance 120.

India—Present Condition and Future Outlook, by Professor S. L. Joshi, Dartmouth College. Dinner preceded the meeting. December 2. Attendance 550.

St. Louis

Dance. November 15. Attendance 132.

San Antonio

The Development of Radio Broadcasting, by J. Cummings, Manager of WOAI Broadcasting Station. Following the meeting those present inspected Station WOAI and Mr. Cummings gave brief explanations of the functions of each part of the station apparatus. November 17. Attendance 68.

San Francisco

Telegraphing Today, by M. V. Merriman, Western Union Telegraph Co. Miscellaneous apparatus, consisting of relays and parts from the various equipment used in telegraph, on display. Following the meeting the members were conducted through the main office of the Western Union Telegraph Co. The exchange was in full operation and all had an opportunity of witnessing the various activities as they normally take place. November 28. Attendance 90.

Saskatchewan

Some Recent Developments in Transformer Design, by C. E. Sisson, Canadian General Electric Co., and Vice-President District No. 10, A. I. E. E. Illustrated with a number of lantern slides. October 20. Attendance 22.

Seattle

Some Fundamentals of Illumination—Old and New, by Professor F. A. Osborn, University of Washington. Two moving pictures followed. A report of the Summer Convention held in Toronto last June was presented by L. N. Robinson, who was the delegate of the Section. November 18. Attendance 60.

Sharon

Semi-Annual Winter banquet meeting. Humor—A Mental Cocktail, by Dr. John L. Davis. December 2. Attendance 180.

Spokane

Spokane River Flow Control for Economic Operation of Hydroelectric Plants, by John A. Tobyn, Washington Water Power Co.;

Motors and Their Application, by Henry L. Vincent, General Electric Co. A report of the Summer Convention at Toronto last June was given by Earl Baughn, who was the delegate of the Section. November 21. Attendance 25.

Springfield

A Mechanical Analogy to the Problem of Transmission Stability, by A. D. Dovjikov, Westinghouse Elec. & Mfg. Co. Refreshments served after the meeting. November 10. Attendance 54.

Toledo

Metal-Clad Switch-Gear, by H. V. Nye, Allis Chalmers Mfg. Co., illustrated with slides. E. B. Featherstone presented a film "A Tourist Trip Through The Rockies," and explained the scenes as they appeared. November 14. Attendance 70.

The Transmission of Personality, by L. S. O'Roark, Bell Telephone Laboratories, Inc. Dinner meeting of the Affiliated Technical Societies of Toledo. December 4. Attendance 275.

Toronto

Copper Mining, Smelting, and Manufacture, by G. S. Mallett, American Brass Co. Moving pictures describing the mining, smelting, and fabricating of copper were presented. November 14. Attendance 88.

Planning to Meet the Development of the Systems of the Hydroelectric Power Commission of Ontario, by A. H. Frampton, H. E. P. C., illustrated with slides. November 28. Attendance 83.

Urbana

The Universe as a Physical Laboratory, by Professor R. H. Baker, Head of the Department of Astronomy, University of Illinois. November 18. Attendance 30.

Utah

Domestic Electric Water Heating, by H. M. Ferguson, Utal Power & Light Co. Informal dinner preceded the meeting. November 10. Attendance 40.

Washington

The Work of the American Engineering Council, by L. W. Wallace, American Engineering Council. Dinner preceded the meeting. November 11. Attendance 46.

Worcester

Construction and Maintenance of the 15 Mile Falls Development of the New England Power Company, by C. R. Olliver, illustrated with slides. November 13. Attendance 60.

Past Branch Meetings

University of Akron

Deion Circuit Breakers, by Mr. Seified, Student. Professor J. T. Walther, Counselor, and H. Shively, Chairman, outlined the activities at the District Meeting held in Philadelphia. October 30. Attendance 11.

Transmission Problems on Long Lines, by Troy Starr, American Tel. & Tel. Co. November 21. Attendance 11.

University of Arkansas

Railway Electrification, by G. V. Smith, Student;

Television, by Robert Hunt, Student. An automatic relay was presented to the school by Wylie Head, who had received it as a trophy of his summer work with the Westinghouse Elec. & Mfg. Co. November 5. Attendance 24.

Armour Institute of Technology

Radio as an Aid to Police, by W. P. Hilliard, Chicago Police Department. Joint meeting with the Armour Radio Association. November 17. Attendance 89.

Discussion on Submarine Tele-

Phones and Telegraph Cables, by Donald M. Detterman, Student;

High-Frequency Radio Beam Transmission, by Morton Fagen, Student. December 1. Attendance 51.

University of British Columbia

The Cathode Ray Oscillograph, by E. Crawford, Student;

Mercury Arc Rectifiers, by Mr. Thomas, Student. November 18. Attendance 17.

Inspection trip to the Ruskin hydroelectric plant of the British Columbia Electric Railway. November 21. Attendance 22.

Polytechnic Institute of Brooklyn

Electrodynamometers for Power Measurement, by T. C. Katsigris, Hub Engineering Corp;

Photelectric Cells, Their Construction and Uses, by R. T. Orth, Radio Corporation of America;

Lightning on Transmission Lines, by Prof. V. Karapetoff. Refreshments were served after the meeting. November 10. Attendance 64.

Bucknell University

Conowingo Hydroelectric Development on the Susquehanna, by C. M. Deatherage, Student;

The Philadelphia Plant of the General Electric Co., by Leighton Herbst, Student. O. R. Sterling, Chairman, outlined the activities of the Institute. November 10. Attendance 12.

California Institute of Technology

The Electrical Equipment of the New Astro-Physics Laboratory, by Emmett M. Irwin, Student. Luncheon preceded the meeting. November 20. Attendance 40.

University of California

After a short business meeting the following papers were presented:

Power, by A. H. Markwart, Pacific Gas & Electric Co.;

Hydroelectric Power Developments in California, by Robert W. Hollis, Student. November 19. Attendance 69.

Business meeting followed by the presentation of two films, as follows:

"The Steel Needle," and "Conquering the Cascade." New officers were announced and introduced. December 3. Attendance 25.

Catholic University of America

Election of officers as follows: David F. Doody, Chairman; C. R. Liekweg, Vice-Chairman; F. D. Vezzosi, Secretary-Treasurer. Professor T. J. MacKavanagh, Counselor, gave a talk on the activities of the Institute. October 11. Attendance 30.

The Photoelectric Cell and Its Applications in Industry, by D. F. Doody, Student. November 11. Attendance 30.

Clarkson College of Technology

Lecture on Photography, by Assistant Professor W. A. Dart, illustrated. Committee reports presented. November 11. Attendance 13.

Inspection trip to the Alogonquin Paper Corporation's Mill at Ogdensburg, N. Y. November 12. Attendance 51.

Clemson College

Inspection trip to the Saluda River Hydroelectric Power Plant. October 22. Attendance 35.

General Power Applications, by A. T. Vick, Student;

Two-Way Television, by H. C. Woodson, Student;

Current Events, by C. B. Stevens, Student; November 20. Attendance 26.

Report of the District Meeting in Louisville, by C. E. Jarrard, Student;

Current Events, by Joe Vance, Student. December 4. Attendance 30.

Colorado Agricultural College

Electrification of Rural Districts, by Mr. Stanbaugh, Public Service Co. of Colorado. November 24. Attendance 18.

University of Colorado

Rambles Through the Rockies, by Eben Fine. Illustrated. November 19. Attendance 30.

The Community and the Engineer, by Herbert S. Sands, President, Denver Chamber of Commerce. Professor Frank A. Eastom gave a short talk on the Summer Convention in Toronto last June. Professor Charles M. McCormick discussed the meetings held by the Denver Section. December 3. Attendance 35.

Cooper Union

Film—"The Theory of Construction and Operation of Electrical Instruments." November 19. Attendance 60.

Cornell University

Radio Beacon, by H. B. Simpson, Student;

Public Address Systems, by A. C. Stallman, Student;

Calculating Boards, by P. J. Glaister, Student;

The Charles Huntley Generating Station, by L. A. Eggelston, Student. December 3. Attendance 30.

Drexel Institute

Demonstration and Explanation of the Theremin, by Fred Farrow, Radio-Victor Corp. November 25. Attendance 60.

Duke University

L. R. Ransom, President, outlined the purposes and aims of the Institute. A. L. deBruyne elected Secretary. October 5. Attendance 17.

The Photoelectric Cell and Some Applications, by Russell Ransom, President;

Television and Recent Developments in that Field, by Stanley G. Flack, Student;

The Condenser Microphone and the Theory of It, by A. L. deBruyne, Secretary. Professor W. J. Seeley, Counselor, urged all to take an active part in the A. I. E. E. activities. October 16. Attendance 30.

Mercury Arc Rectifiers, by C. F. Brethal, Student. October 30. Attendance 10.

Illumination, by R. L. Peppell and W. F. Weaver, Students. November 13. Attendance 18.

University of Florida

A Trip through the Inglis Power Plant of the Florida Power Corporation, by J. L. Wolcott, Student;

A Modern Explanation of the Ohm's Law, by J. L. Sanders, Student. Film—"Hydroelectric Power Production in the New South." November 17. Attendance 22.

Reports of the recent District Meeting held in Louisville were given by Professor Joseph Weil, Counselor, and C. V. Booth, Chairman. December 3. Attendance 37.

Georgia School of Technology

Steam-Turbine Developments and Principles of Operation, by P. C. Eppelshimer, Westinghouse Elec. & Mfg. Co. November 12. Attendance 71.

Inspection trip to Plant Atkinson of the Georgia Power Company. Joint meeting with the A. I. E. E. and A. S. M. E. Sections. November 24. Attendance 100.

Harvard University

The Fifteen Mile Falls Hydroelectric Development, by E. W. Dillard, New England Power Construction Co., illustrated with lantern slides and motion pictures. November 13. Attendance 180.

State University of Iowa

The Automatic Garage, by Mr. Colony, Student;

Telephones in the Rough, by Mr. Cutler, Student;

Sound Reproduction, by Mr. Duckett, Student. November 19. Attendance 29.

Practical Uses of the Photoelectric Cell, by Mr. Fitzgerald, Student. Professor Edwin Kurtz, Counselor, and J. W. Campian, Chairman, gave reports of the Conference on Student Activities held in Chicago. December 3. Attendance 33.

Kansas State College

Success, by Professor L. M. Jorgenson. Professor R. G. Kloeffler, Counselor, gave a talk outlining the purposes and aims of the A. I. E. E. Entertainment and refreshments followed. October 24. Attendance 180.

Current Events, by S. W. Graham, Student;

Opportunities in Public Utility Work, by Paul Ayers, Student;

Television, by Mr. Burgin, Student. Moving pictures on the subject of X-rays presented. (Afternoon session.) October 30. Attendance 54.

The program of the evening meeting was the same as that presented in the afternoon. October 30. Attendance 53.

Current Events, by W. Tolley, Student;

Photoelectric Cells and Their Applications, by K. D. Cornell, Student;

L. E. Baldwin, Kansas Power & Light Co., gave a talk on public utility work and its functions, and also the possibilities for college graduates with these companies. Film—"Thomas Edison." (Afternoon session.) November 6. Attendance 56.

The program of the evening meeting was the same as that presented in the afternoon. November 6. Attendance 55.

University of Kansas

Television, by C. B. Brown, Student. Demonstrated.

Reports of inspection trips to Keokuk, Chicago, Milwaukee, and other cities by several students. November 13. Attendance 77.

Some Mechanical Engineering Problems in a Modern Oil Refinery, by W. L. Mathews, Standard Oil Co.;

Some Construction Details of an Industrial Power Plant, by C. O. Boynton, Standard Oil Co.;

Toll Telephone Plant Construction, by J. H. Schweitzer, Southwestern Bell Telephone Co., illustrated with slides;

Economic Design of Inter-City Communication Facilities, by L. F. Burwick, Southwestern Bell Telephone Co. Joint meeting of the Kansas City Sections and Univ. of Kans. Branches of the A. I. E. E. and A. S. M. E. December 4. Attendance 175.

University of Kentucky

Power of the East River Generating Station, by C. O. Fury, Student;

Power of the Pacific Light and Power Company, by F. Y. Carter, Student;

Membership Qualifications, Grades, and Entrance Requirements of the A. I. E. E., by Professor W. E. Freeman, Counselor. October 18. Attendance 41.

Scientific Aspects of Thomas Jefferson's Life, by Professor W. S. Rodman, Vice-President, District No. 4, A. I. E. E. November 17. Attendance 45.

Nitrogen Fixation Process, by S. H. Wise, Student;

W. O. Richmond, Student, gave a summary of a new method of removing water from the tanks of submarines. December 3. Attendance 41.

Lehigh University

Applying an Engineering Education, by H. G. Harvey, Associated Gas & Electric Co.;

The Screen-Grid Radio Circuit, by L. R. Wanner, Student. Paul W. Seal, Chairman, outlined the proposed program for the coming year; also the aims and activities of the A. I. E. E. November 7. Attendance 100.

Lewis Institute

Your Chicago, by T. Price, Commonwealth Edison Co., illustrated with moving pictures. December 5. Attendance 76.

Marquette University

Short papers read by several students. November 13. Attendance 22.

Massachusetts Institute of Technology

The Generation and Distribution of Electric Power, by E. S. Mansfield, Edison Electric Illuminating Co. of Boston. Film—"More Power To You." November 20. Attendance 230.

Inspection trip to the Milk Street Manual Exchanges and the Kenmore Automatic Exchanges of the New England Telephone & Telegraph Co. December 3. Attendance 30.

Michigan College of Mining and Technology

Motor Maintenance and General Maintenance of Electrical Equipment, by Mr. Zimmerman, Westinghouse Elec. & Mfg. Co. Committees appointed to take care of the arrangements for the Electrical Show to be held next May. November 7. Attendance 61.

The Student Training Course at Westinghouse, by M. D. Crowell, Secretary. November 19. Attendance 29.

James Rowley, Student, outlined his experiences with the Detroit Edison Co. during the past summer. December 3. Attendance 25.

University of Michigan

What Does an Engineer do in a Manufacturing Plant, and How? by A. M. Dudley, Westinghouse Elec. & Mfg. Co. November 12. Attendance 100.

The Production of Electric Power, by A. R. Smith, General Electric Co. November 18. Attendance 110.

School of Engineering of Milwaukee

The Water Supply of Muncipalities and the Selling of Water Supply Equipment, by E. Roger, Layne-Northwest Pump Co. Refreshments served. November 12. Attendance 150.

Missouri School of Mines and Metallurgy

The Effect of Electricity upon the Nervous System, by J. E. Stokes, Student;

My Summer Experiences, by A. R. Baron, Student. November 19. Attendance 21.

My Summer Experiences, by J. D. Shelton, Chairman. December 3. Attendance 13.

University of Missouri

Design of Alternators, by J. W. Logan, Student. November 12. Attendance 57.

Montana State College

A Small Motor with a Low Starting Current, taken from the *Electric Journal*, presented by Wesley C. Funk, Student;

A New Portable Oscillograph, taken from the A. I. E. E. Journal, presented by Manley Goldberg, Student;

The Development of the Modern X-Ray Generating Apparatus, taken from the *General Electric Review*, presented by N. Grebeldinger, Student. November 6. Attendance 147.

Electricity vs. Steam, taken from *World's Work*, presented by Arthur Sheldon, Student;

Short Cuts in Mathematics, by Walter Williams, Student;

A Portable Emergency Local Distribution Substation, taken from the *General Electric Review*, presented by Harry Beck, Student;

Scheduled Speed Increased by Electrification, taken from the *Electric Railway Journal*, presented by Howard Freeman, Student. November 13. Attendance 145.

N. E. L. A. Electrification Report, taken from *Railway Age*, presented by Vern Hankins, Student;

Radio now has Tone Control, taken from *Popular Science Monthly*, presented by Curtis Hanson. November 20. Attendance 146.

University of Nebraska

What I would do if I were a Senior now, by F. J. Gunther, Iowa-Nebraska Light & Power Co. December 3. Attendance 30.

Newark College of Engineering

Electrification of the Lackawanna, by Edward Anson, Jackson & Moreland;

Development of Mercury Arc Rectifiers, by W. R. Ackor, Chairman, illustrated. November 17. Attendance 41.

University of New Hampshire

Retox Rectifiers, by Marshall E. Bowker, Student;

Multiplex Printers, by Arthur G. Pinkham, Student. October 18. Attendance 34.

Film—"Power Transformers." November 15. Attendance 33.

Theory of Corona Loss in Power Transmission, by C. G. Matoian, Student;

Demonstration of the Left-Hand Motor Rule, by R. E. Sawyer, Student;

Horn-Gap Lightning Arrestep, by A. G. Pinkham, Student. L. E. Potts and L. E. Moore, Students, demonstrated the above with high-voltage apparatus, and conducted a few other experiments with the same apparatus. November 22. Attendance 24.

Some Hydroelectric Developments in New Hampshire and Vermont, by P. E. Rolfe, Student;

Manufacture and Uses of Carborundum, by L. A. Barker, Student;

Sparking in a Partial Vacuum, by M. H. Riley, Student. November 29. Attendance 30.

University of New Mexico

The Radio Knife, by C. E. Henderson, Chairman. November 13. Attendance 15.

New York University

Debate—Resolved: That water power in New York States be Owned, Operated, and Distributed by the State. November 10. Attendance 21.

Tying Up of Power Networks, by C. J. Ridgley, Student. November 24. Attendance 14.

North Carolina State College

Review of the Life of Steinmetz, by C. M. Smith, Student;

Railroad Signaling, by J. W. Sutherland, Student. November 18. Attendance 31.

A report of the District Meeting held at Louisville was given by R. C. Kirk, Chairman. December 2. Attendance 30.

North Dakota State College

Film—"Power." November 20. Attendance 85.

Film—"From Coal to Electricity." December 4. Attendance 52.

University of North Dakota

A New Screen-Grid Tube, by William Denk, Student;

William Spriggs and A. W. Eynon, Students, gave a practical demonstration of the current-illumination characteristics of the photoelectric cell, and also its color sensitivity. November 12. Attendance 18.

Northeastern University

Electrical Units, by Dr. A. E. Kennelly, Harvard University. Refreshments served. November 4. Attendance 89.

University of Notre Dame

The Street Lighting System of South Bend, Indiana, by Frank Mills, Indiana Michigan Electric Co.;

Starting and Reversing Single-Phase Induction Motors, by John Staunton, Student;

High-Frequency Induction Furnaces, by A. White, Student;

Patrick Murray, Student, presented the regular digest of engineering news. November 17. Attendance 73.

Ohio Northern University

The Effect of Electric Shock, by J. M. Stewart, Student. November 20. Attendance 33.

Ohio University

Films as follows: "Beyond the Microscope," "Pillars of Salt," and "The Continuous Process of Making Sheet Steel." November 17. Attendance 12.

Oklahoma A. & M. College

Construction and Care of Transformers, by W. E. Nichols, Student;

Evolution of the Transformer, by Hubert Short, Student, illustrated with slides. November 20. Attendance 10.

Oregon State College

General discussion of Branch activities. November 10. Attendance 55.

Electric Power from Hogged Fuel and the Relation of Steam to Water Power Plants, by C. P. Osborne, General Electric Co., illustrated with slides. Films—"Blasting the Water Highways of America," and "Hydroelectric Power Production in the New South." November 19. Attendance 38.

Pennsylvania State College

Smoker and Annual Get-Together. October 8. Attendance 91.

Talks by five Students on their summer experiences. October 29. Attendance 38.

Film—"From Mine to Consumer." November 5. Attendance 53.

The Development Engineer in Manufacture, by D. Levinger, Western Electric Co., illustrated with slides and motion pictures. November 18. Attendance 93.

University of Pennsylvania

Motion pictures. December 5. Attendance 26.

University of Pittsburgh

Lightning, by R. G. Woessner, Student;

H. K. Aalborg, Student, related his experiences as circuit breaker engineer while employed by the Westinghouse Electric & Mfg. Co. October 9. Attendance 116.

Transoceanic Communication, by R. A. White, Student;

D. N. Burdette, Student, outlined the design and operation of magnetic strain gages as developed by the Westinghouse Electric & Mfg. Co. October 16. Attendance 110.

Biography of Faraday, by Robert Canning, Student;

D. W. Burns, Student, outlined some early developments in electricity. October 23. Attendance 109.

Modern Railways, by C. I. Staples, Westinghouse Elec. & Mfg. Co. Movies, refreshments, and entertainment followed. October 30. Attendance 85.

H. J. Stoneman, Student, described the operation of the West Penn Power Company's Coal Mine at Springdale;

W. J. Wherry, Student, outlined the manufacture of rubber as carried on at Akron, Ohio. November 6. Attendance 113.

Modern Electric Refrigeration, by A. J. Mattes, Student;

F. A. Mallisee, Student, traced the historical development of all types of meters. November 13. Attendance 113.

Development of Transmission Lines, by L. A. Terben, West Penn Power Co. November 20. Attendance 118.

Pratt Institute

Panel Boards, by L. Johnson, Student;

Railroad Control and Railway Signaling, by C. Schimke, Student. November 13. Attendance 30.

Westinghouse Test, by John Cook, Student. December 3. Attendance 50.

Princeton University

Election of officers as follows: Frank L. Thomson, Chairman; E. E. George, Secretary. December 4. Attendance 13.

Purdue University

Lecture on the Magnetic-Type Oscillograph, by Professor G. V. Mueller;

New Permanent-Magnet-Type Oscillograph, by D. A. MacAffer, General Electric Co. November 20. Attendance 125.

Rensselaer Polytechnic Institute

Description of the Emmet Mercury Vapor Process equipment installed by the General Electric Co. in the South Meadows station of the Hartford Electric Co., by James Orr of the same company. November 11. Attendance 285.

Rhode Island State College

Film—"Buried Sunshine." November 24. Attendance 30.

Business Meeting. December 8. Attendance 7.

Rose Polytechnic Institute

Film—"A History of the Electrical Industry." November 24. Attendance 37.

Lifting Magnets, by Mr. Richardson, Student;

Robert Roach, Student, gave a report of the Conference on Student Activities held in Chicago. December 5. Attendance 34.

Rutgers University

Recent Developments in the Bell System, by Mr. Birch, Student;

Opportunities for Employment in the Bell Laboratories, by Mr. Wolff, Student. October 28. Attendance 22.

Rubber-Covered Cables, by Milton Trompen, Student;

Film—"The Single Ridge." November 11. Attendance 25.

Kenotron and Thyratron Tubes, by Jacob Rudnitsky, Student;

Rotary Converters, by Fred Kent, Student;

Comments on Mercury Arc Rectifiers, by Prof. Pumphries. November 24. Attendance 19.

Santa Clara University

Films"—Hydroelectric Water Tunnels," and "Channel Excavations." November 5. Attendance 31.

Survey of Aeronautics, by Walter Van Haitsma, Boeing Aircraft Co. November 19. Attendance 63.

Oil Circuit Breakers, by Roy Wilkins, Pacific Electric Mfg. Corp., illustrated with slides. November 19. Attendance 40.

Inspection trip to Station A—Pacific Gas & Electric Co. Generating Plant. November 24. Attendance 39.

University of South Carolina

The Deion Circuit Breaker, by H. L. Stokes, Chairman. Film—"Hydroelectric Power Production in the New South." November 17. Attendance 34.

The Engineer's Outlook on Life, by S. Hammon. Professor T. F. Ball, Counselor, and H. L. Stokes, Chairman, outlined the events at the District Meeting held in Louisville. November 24. Attendance 30.

Business Meeting. December 1. Attendance 9.

South Dakota State School of Mines

Needed Improvements in Distribution Systems, by Lee Boyer, Consolidated Power & Light Co. Stanley Sickle and Clifford Spilker, Students, outlined their experiences during the past summer on construction work with the American Tel. & Tel. Co. November 19. Attendance 34.

University of Southern California

Lecture on The Trails of the High Sierra, by Professor N. C. Clark, illustrated. November 29. Attendance 45.

Lecture by Professor N. C. Clark on the region near and including Yosemite Valley. November 5. Attendance 37.

Films—"Blasting the Water Ways of America," and "Hydroelectric Power Production in the New South." November 12. Attendance 34.

Industrial Lighting, by Willard Bausman, Holophone Illuminating Co. November 19. Attendance 31.

Blind Landing of Aeroplanes, by Walter Weis, Student. December 3. Attendance 25.

Southern Methodist University

Professor H. F. Huffman, Counselor, outlined the aims and activities of the Institute. Election of officers as follows: F. H. Gable, Chairman; I. Frauman, Vice-Chairman; Porter Lindsley, Jr., Secretary-Treasurer. October 15. Attendance 37.

Underground Distribution System of the Dallas Power & Light Co., by H. H. Robinson of the same company. Illustrated. November 12. Attendance 30.

Demonstration of a Short-Wave Sending Set, by D. J. Tucker, Student;

Demonstration of a Thermocouple, by R. L. Allen, Jr.;

Laboratory Experiments with Transformers, by Carlos Burnett, Student. Joint meeting with the Dallas Section. November 17. Attendance 80.

Stanford University

E. A. Crellin, Vice-Chairman, San Francisco Section, A. I. E. E., discussed plans for closer relationship between the Branches and the Section. Professor T. H. Morgan, Counselor, outlined the new by-laws concerning Student enrolment. October 21. Attendance 17.

Aeronautical Radio Communication, by Eugene Sibley, reviewed by Robert Triplett, Student;

Relay Metering, by D. A. Murray;

A New System of Speed Control for A-C. Motors, by A. M. Rossman, reviewed by V. Siegfried, Chairman;

G. S. Kimball, Student, described the new equipment being installed in the Electrical Engineering Laboratory. November 25. Attendance 15.

Syracuse University

Trolley Buses, by E. W. Schweitzer, Student;

Automatic Train Control, by D. W. Phelan, Student. November 14. Attendance 25.

Recording of Sound Pictures, by M. J. Kraska, Student;

Airport Lighting, by C. R. Anderson, Student. Illustrated. November 21. Attendance 25.

Two illustrated lectures presented as follows: The Evolution of the Transformer, and 50,000 Kv-a. Synchronous Condensers. December 5. Attendance 25.

University of Tennessee

Get-Together Meeting. December 2. Attendance 52.

Texas A. & M. College

Electric Shock, by H. A. Eddins, Student;

Resuscitation from Electric Shock, by J. A. Shellberg, Student. November 11. Attendance 60.

Texas Technological College

Dean W. J. Miller, Counselor, and Walter Burns, Chairman, outlined the aims and purposes of the Institute. Committee appointments announced. October 8. Attendance 19.

Film—"The Conowingo Hydraulic Dam." November 7. Attendance 14.

The Adapting of Electricity to Railroads and Large Ships, by Wm. Walker, Student;

Tuco (a large generating plant which is nearing completion), by Hulbert J. Allen, West Texas Utility Co. November 19. Attendance 50.

Inspection trip to the new power plant of the Texas Utility Co. November 25. Attendance 35.

University of Texas

Boiler Feed-Water Control, by C. A. Glover, Student. November 13. Attendance 18.

University of Utah

New Developments in Hydroelectric Plants, by L. E. Painter, Student;

The Relationship between the Big Open Air Mine at Bingham, Utah, and Electricity, by Ray Bohne, Student. October 28. Attendance 21.

Film—"From Mine to Consumer." December 2. Attendance 24.

University of Vermont

Westinghouse Method of Frequency Control, by P. H. Thomas, Student;

The Selsyn Motor, by M. L. Joslin, Student. November 18. Attendance 27.

Films as follows: "Blasting the Water Highways of America," "Building New York's Newest Subway," "Driving the Cascade Tunnel," and "Hydroelectric Power Production in the New South." Joint meeting with the A. S. M. E. December 3. Attendance 60.

Virginia Military Institute

Improved Lighting on Our Highways, by Mr. Ould, Student;

Industry's Tribute to George Westinghouse, by Mr. Woodson, Student;

Railroad Electrification, by Mr. Moore, Student;

The Talking Picture Apparatus in J. M. Hall, by Mr. Stokes, Student;

Low Cost of Construction, by Mr. Welch, Student. October 16. Attendance 47.

An account of the activities of the District Meeting held in Louisville was given by C. G. King, representative of the Branch. December 4. Attendance 47.

Virginia Polytechnic Institute

Professor C. Lee, Counselor, and R. E. McDaniel, A. B. Pritchard, and E. L. Rowell, Students, outlined the activities of the District meeting held in Louisville. November 25. Attendance 17.

Steinmetz, by R. C. Hoffman, Student;

Sound Reproduction, Western Electric Method, by W. J. Pritchard, Student;

Economy and the Engineer, by C. V. Burgess, Student. Professor C. Lee, Counselor gave a talk on some of the activities of the Institute. December 4. Attendance 42.

University of Virginia

Development of Short-Wave Radio Communication, by W. B. Campfield, Student;

Development of Broadcast Radio, by G. B. Miller, Student. Short talk by Professor W. S. Rodman, Counselor. November 7. Attendance 16.

Washington State College

Film—"An Electrical Travelogue." November 12. Attendance 36.

Harry Skaglund, Student, outlined a trip he took to Diablo Dam, near Seattle, last summer. Committee chosen to make arrangements for the A. I. E. E. banquet. November 25. Attendance 16.

University of Washington

Switchboard Equipment, by James MacDougal, Roller Smith Co., illustrated with slides. November 6. Attendance 20.

The Power Company's Goat, by P. L. Morton, Student. November 13. Attendance 23.

Washington University

Radio Servicing, by Richard O-Denning, Student. November 6. Attendance 26.

Electrical Communications, by J. C. Rathman, Postal Telegraph Co. Film—"Under the Seven Seas." November 20. Attendance 17.

University of Wyoming

Rectifiers used in Radio Apparatus, by Floyd Wickencamp, Student;

Effect of Anti-Knock Compounds on Fuels Used in Internal Combustion Engines, by Vincent Bowles, Student. Joint meeting with the A. S. M. E. November 4. Attendance 17.

Electric Fish, by E. Hemenover, Student;

A New Method of Removing Scale and Corrosion from Steel, by J. Sillasen, Student;

Power from the Ocean, by C. Horton, Student. November 18. Attendance 11.

Yale University

Advantages and Disadvantages of Holding Corporations, by R. A. Hockley, Student;

Regulation of Holding Companies, by E. R. Eberle, Student;

The General Electric Unemployment Insurance Plan, by L. A. Autuori, Student. November 18. Attendance 13.

Power System Stability, by Professor G. C. Dahl, Massachusetts Institute of Technology. November 25. Attendance 42.

Employment Notes

Of the Engineering Societies Employment Service

Positions Available

SALES ENGINEER, who has had experience selling resistance units and rheostats for industrial and radio applications. Apply by letter giving experience in full. Headquarters, Middle West. W-2120.

◆

Men Available

ELECTRICAL ENGINEER, college graduate, good character. Approximately 13 years' practical experience divided as follows: 9 months' clerical work, 6 months maintenance and switchboard operating in high tension power plants, 12 years' detailed and general engineering of low voltage power plants. C-8328.

1930 GRADUATE ELECTRICAL ENGINEER, Rensselaer Polytechnic Institute. Ten months' experience with sound picture industry; five months' thesis experience investigating acoustics of broadcasting studio, miscellaneous experience servicing radio receivers. Location, New York City district. Available short notice. C-8407.

ELECTRICAL SUPERINTENDENT OR FOREMAN, 12 years' experience taking charge; can handle any size job or jobs. Sober, reliable and industrious. Best of references. C-8464.

1929 GRADUATE, American, E. E. degree: 14 months on General Electric Test Course. Interested in research; vacuum tube application work. Experience covers above, also testing all types of electrical equipment. C-1879.

ENGINEER, EXECUTIVE, B. S. degree; 20 years' experience in engineering, contracting and purchasing, desires permanent connection with large industrial company or as a local representative. Location, New York City. B-5050.

ELECTRICAL ENGINEER, 27. Experience includes: Westinghouse oscillograph operation; raw material inspection; pump, boiler and steam turbine tests; electrolysis survey of subway cables; electrical construction in finished buildings. Laboratory work preferred in Metropolitan area. C-8424.

GRADUATE ELECTRICAL MECHANICAL ENGINEER, 36, desires connection with public utility, industrial firm in power station operation as engineer, assistant to superintendent or engineer. Ten years' experience power plant test, operation, design, construction, maintenance. Three years electrical engineer for industrial concern. Two years assistant to power engineer. B 8379.

1930 GRADUATE ELECTRICAL ENGINEER, 22. Experience: six months in boiler-testing gang, three months testing centrifugal

ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco
N. D. Cook, Manager

205 West Wacker Drive
Chicago
A. K. Krauser, Manager

31 West 39th St.
New York
W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

Men Available.—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

Opportunities.—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

Voluntary Contributions.—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

Answers to Announcements.—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

water pumps, one year maintaining test equipment in radio receiver manufacturing plant. Prefers work in radio, sound reproduction, or communication; however, will be interested in other work. Location, preferred in or near New Jersey. C-8452.

ELECTRICAL ENGINEER AND EXECUTIVE, married; 20 years' experience in electric distribution and maintenance problems. Desires position in East or South with public utility company. Available immediately. C-7700.

ELECTRICAL ENGINEER, 28, single, B. S. in E. E. 1924. Six years' experience large public utility in utility economics including water power values, financial, load forecasts, power studies, studies of system development, rate studies, unit costs, research work, general matters of financial, economic nature; desires position, public utility, industrial concern. Location, preferably South. C-6985.

GRADUATE ELECTRICAL ENGINEER, 34, married, desires connection with future. Experienced in power and substation work, investigations, estimates, specifications, design and construction, control and relay work, related calculations, investigation of system conditions in connection with expansion and load additions. Industrial substations. Foreign languages. U. S. Citizen. Location, United States or Foreign. B-6560.

ENGINEER, with sales experience over a wide territory and experienced in electrical, mechanical and rubber industries in development laboratory and production. Offers his services. B-7829.

SALES ENGINEER, 27, single, graduate engineer. Engineering and sales experience of five years with leading control manufacturer. Desires position with sales department of an electrical concern or motor-control specialist for a fast growing electrical jobbing house. C-8390.

ELECTRICAL AND ILLUMINATING ENGINEER, 41, married; 23 years' experience, wireman to superintendent, estimator and engineer, instructor in applied electrical engineering in technical school. Experienced wiring power stations, commercial and industrial buildings. Five years' engineering for architects, writing specifications and designing electrical installations for office buildings, hotels, hospitals, industrial buildings. C-8460.

GRADUATE ELECTRICAL ENGINEER, 30. Two years' railroad shop and power plant experience, 4¾ years' large eastern railroad electrical engineer's office, drafting and design, appraisal electrical and power plant machinery, investigation and reports of engineering projects. Nineteen months electrician, U. S. Shipping Board diesel and diesel-electric motorships. Speaks Spanish. C-8160.

ELECTRICAL ENGINEER, 32, married, B. S. Nine years with large public utility. Six years power station and substation design and layout, including purchase of equipment and materials. Three years cable inspector and tester. Three years' practical field experience. Four years' clerical and executive experience. Location, Metropolitan, New York. B-3698.

ELECTRICAL ENGINEER, married, 35. Several years with design, construction corporation on electrical design, construction, starting up, and specifications, covering large power plants, industrial electric drives and auxiliaries. Several years with large manufacturer of electrical equipment, designer, switching, control, general engineer. Experience writing reports and some in technical paper writing. B-3172.

ELECTRICAL DESIGNER, age 38, married. Fourteen years' public utility experience, five different corporations, power plant, switching station, substation, both indoor and outdoor. Desires connection with public utility or industrial organization. Available now. Location preferred, East. C-8490.

RECENT GRADUATE ELECTRICAL ENGINEER, married, age 24. Location, Northern United States. Available now. C-7975.

ELECTRICAL ENGINEER, graduate Georgia Technology 1930, cooperative plan. Worked alternate months, five years substation maintenance and office.

GRADUATE ELECTRICAL ENGINEER, American, 31, married; eight years' public utility experience, hydroelectric developments, high-tension switching stations and distribution substations complete engineering design and supervision of several major developments in the United States and in South America; seeks permanent connections. Speaks, German and Spanish. C-8470.

SALES ENGINEER, 33, married, Chilean Technical graduate, Westinghouse graduate students course. One year University of Pennsylvania; seven years of actual sales work in Mexico and Chile with Westinghouse. Speaks Spanish and English fluently. Desires location in utility or manufacturing company. Location, immaterial. Available immediately. C-8524.

GRADUATE, 1929 with B. S. in electrical engineering, 23, desires position with railway or public utility company. One year Westinghouse student course and has some diagram experience. Location, Middle West or Pacific Coast preferred. C-8523.

MECHANICAL-ELECTRICAL ENGINEER, with 15 years' experience in layout, construction and operation of industrial plants, seven years' design of power plants, five years' machine design, 2 years' machine shop practise, engineering college graduate. Desires position as engineer, chief draftsman or in similar capacity. Available immediately. B-2492.

GRADUATE ELECTRICAL ENGINEER, single, 31, solicits inquiries. Nine years' experience design of power stations, substations and industrial plants, also outdoor substations. Worked with Westinghouse in Pittsburgh and New York Edison Company. Speaks and writes German. Knowledge of French, Spanish. Will locate anywhere. Available immediately. First-class references. C-2522.

ENGINEER, ELECTRICAL, B. S.-E, E. Over 20 years' experience on power plants, substations and industrial plants. Ten years' experience on power plants, substations and industrial plants. Ten years' as designer and checker; ten years' as assistant electrical engineer, covering specifications, supervision of design, purchase of equipment, estimates, consultation, correspondence, etc. Available now. Will accept any reasonable offer. C-3785.

FIRST-CLASS TROUBLE SHOOTER wants work at once. Eight years in public utility and industrial plants. I. C. S. graduate in E. E. and associate A. I. E. E. C-8522.

RADIO ENGINEER, B. S. in E. E., 23, one year in general radio research laboratory. One year as design engineer with radio-receiver manufacturer. Desires position of similar character in laboratory of receiver manufacturer or allied electrical activity. C-8521.

TRANSMISSION AND DISTRIBUTION ENGINEER, desires position in tropical climate. Now superintendent of a tramway in City in Brazil. Experienced in transmission of Irish nationality, speaks Portuguese. Holds first-class diploma Foradoz House, Graduate I. E. E. C-8519.

ELECTRICAL ENGINEER, graduate Georgia Tech. 1930, cooperative plan. Worked alternate months, five years' substation maintenance and office engineering. Rebuilding transformers, switches, lightning arresters, work with electric furnaces, rectifiers, motors, etc. Checking and mapping distribution systems, work orders. Single, excellent physical condition. Desires position, preferably with public utilities. Location, immaterial. C-7847.

ELECTRICAL-MECHANICAL ENGINEER, executive; 23 years' diversified experience as an engineer and executive in industrial plant equipment and operation. Particularly successful in present connection along lines of mechanical plant improvement and in obtaining employee cooperation through personnel training. Can refer freely to each connection held. C-7839.

SUPERINTENDENT, married, 42; 20 years' experience in electrical construction of power plants, automatic railway substations and mercury arc rectifiers. Desires connection with public utility or large manufacturing company. Available because company discontinued construction. C-8520.

SUPERINTENDENT, general foreman or field engineer for construction company or utility, (electric, gas, or water) on construction, maintenance or operating. Young, energetic, ability and experience handling large crews and jobs of many details. Good organizer. B-9380.

ELECTRICAL ENGINEER, graduate Union College, 1924, age 28, married, good appearance, 15 months General Electric Test Course. Four years' public utility operation; 15 years' noncommercial radio experience. Location, East. Available at once. C-4182.

ELECTRICAL ENGINEER, B. S. degree, 33, Westinghouse sales course, 15 months sales assistant, three years technical advertising, four and one-half years development, sales, surveys on oil-electric locomotives. Executive ability. Desires sales position electric traction or industrial electrical equipment; or engineering with railroad electric-traction department. References. Location will consider. C-7545.

GRADUATE ENGINEER with strong theoretical background. Extensive practical experience in public relations, valuation, rate-making, special economic studies, investigations and research. Well qualified as a junior executive for large industrial or public utility corporation, or director of research special investigations or publicity. Now engaged as executive. Available on reasonable notice. C-6733.

GRADUATE ELECTRICAL ENGINEER, 34; power-house, railroad shop, steel-mill electric operation, repair and test experience; power-plant, substation, railroad electrification design; posted on economic and financial fundamentals and statistics; six languages. Valuable to management, financial, industrial organization. C-6952.

ELECTRICAL ENGINEER, 36, experienced in every phase of construction and maintenance (including South America), central stations, substations, inspections, tests, distribution systems, pole lines; one year operating. Desires position at home, or abroad, will represent manufacturer in Brazil; elsewhere considered. Languages, English, French, Portuguese, working knowledge Spanish, German, Italian. Best references. Available immediately. C-2021.

ADVERTISING-ELECTRICAL ENGINEER, 38, extensive and varied career, chiefly in executive capacities. Author of technical articles. Desires opportunity in advertising with either agency, publishing house or sales counsel. Initial salary secondary, where engineering background, wide acquaintanceship, originality, ability to analyze, and proper personality, may be capitalized. B-9079.

GRADUATE ELECTRICAL ENGINEER, B. S. degree, single, 24. Desires position along lines of design, development, or experimental work in industrial, railway electrification, or utility fields. Two years' General Electric test. Available now. Location, East or Middle West. C-4583.

ENGINEER, E. E. degree, age 30, married. Wide experience in layout, design and research of small electrical parts, radio, motion picture and sound system apparatus. Desires position in laboratory or drafting room. A-1 references. Available immediately. Location, New York. B-5138.

ELECTRICAL ENGINEER, 32, married. Nine years' general testing and development experience including railway equipment, with exceptional practical knowledge of power mercury arc rectifiers. Desires position in test or operating departments, of public utility or electric railroad, South, East or Chicago. C-7875.

ELECTRICAL ENGINEER, 36, single, European education, North American training, good executive, 9 languages. Eight years' experience construction, maintenance, operation large public utility plants. Seven years sales, various branches. Expert in exports and government supplies. Traveled over the world. Adaptable to any country, climate. Available now. Desires position abroad. C-8351.

ELECTRICAL ENGINEER, 24, married. Desires engineering work. Has had experience with oscillographs and radio. Holds second grade commercial wireless operators license. Has public utility test experience. Also surveying experience. Personal interview desired. C-3035.

SALES AND EXECUTIVE ENGINEER, trained at Worcester Polytechnic Institute. Six years' sales experience; straight sales engineering, jobbing sales, sales promotion and management. Has contacted with electrical and mechanical companies. Traveled East, Middle West, South. Well acquainted with New England. C-5431.

GRADUATE ELECTRICAL ENGINEER, 26, one year's experience large public utility, power engineer, 1½ years research department large manufacturing company. Experienced, design of electromagnetic appliances, mechanical design and equipment layouts. Drafting experience. Best references. Ability to handle men. Desires connection, public utility, motor or industrial control manufacturing. Available two weeks' notice. C-7737.

ELECTRICAL-MECHANICAL ENGINEER with extensive and mature experience in the United States and foreign fields would like a connection where his knowledge and experience would be of most benefit, design, specifications, estimates construction, superintendence of operation power and industrial plants, engineering correspondence, engineering sales—whatever you need. C-408.

GRADUATE ELECTRICAL ENGINEER, age 29, married. Five years' practical experience construction and maintenance work. C-8539.

SUPERINTENDENT of distribution, 43, married. Electrical and industrial management. Twenty years' electric utility operating experience, in engineering, construction, operation, maintenance of distributing and transmission lines, substations, first aid and educational work. Has sufficient public utility operating experience to qualify for position of superintendent. Demonstrated record of executive ability. C-8411.

ELECTRICAL ENGINEER, graduate, E. E. degree, 28, married. Three years' experience, relays, relay studies large electric power and light utility, operating New York City. Three years' testing, design and development work on new electrical appliances and materials Experience includes considerable outside contact leading electrical manufacturers. Available immediately. Location, New York City. B-8793.

Membership

Applications for Election

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before January 31, 1931.

Personnel

Institute Officers 1930-1931

President

(Term expires July 31, 1931)
WILLIAM S. LEE

Junior Past Presidents

(Term expires July 31, 1931)
R. F. SCHUCHARDT

(Term expires July 31, 1932)
HAROLD B. SMITH

Vice-Presidents

(Terms expire July 31, 1931)
HERBERT S. EVANS (District No. 6)
W. S. RODMAN (District No. 4)
C. E. FLEAGER (District No. 8)
E. C. STONE (District No. 2)
C. E. SISSON (District No. 10)

(Terms expire July 31, 1932)
H. V. CARPENTER (District No. 9)
G. C. SHAAD (District No. 7)
I. E. MOULTROP (District No. 1)
H. P. CHARLESWORTH (District No. 3)
T. N. LACY (District No. 5)

Directors

(Terms expire July 31, 1931)
F. C. HANKER
E. B. MEYER
H. P. LIVERSIDGE

(Terms expire July 31, 1932)
J. ALLEN JOHNSON
A. M. MacCUTCHEON
A. E. BETTIS

(Terms expire July 31, 1933)
J. E. KEARNS
F. W. PEEK, JR.
C. E. STEPHENS

(Terms expire July 31, 1934)
A. B. COOPER
A. E. KNOWLTON
R. H. TAPSCOTT

National Treasurer

(Term expires July 31, 1931)
W. I. SLICHTER

National Secretary

(Term expires July 31, 1931)
F. L. HUTCHINSON

General Counsel

PARKER & AARON
30 Broad Street, New York, N. Y.

Local Honorary Secretaries

T. J. Fleming, Calle B. Mitre 519, Buenos Aires, Argentina, S. A.

H. W. Flashman, Aus. Westinghouse Elec. Co., Ltd., Cathcart House, 11 Castlereagh St., Sydney, N. S. W., Australia.

Frederick M. Servos, Rio de Janeiro Tramways Lt. & Pr. Co., Rio de Janeiro, Brazil, S. A.

A. P. M. Fleming, Metropolitan Vickers Elec. Co., Trafford Park, Manchester, England.

A. S. Garfield, 173 Boulevard Haussmann, Paris (8e), France.

Renzo Norsa, Via Caravaggio 1, Milano 25, Italy.

P. H. Powell, Canterbury College, Christchurch, New Zealand.

M. Chatelain, Lesnoi Polytechnic Institute, Apt. 27, Leningrad, U. S. S. R.

Axel F. Enstrom, Ingeniorsvetenskapsakademien, Stockholm, Sweden.

W. Elsdon-Dew, P. O. Box 4563, Johannesburg, Transvaal, Africa.

GENERAL COMMITTEES

Executive Committee

W. S. Lee, Chairman, 535 Fifth Avenue, New York, N. Y.
J. Allen Johnson, W. I. Slichter,
A. M. MacCutcheon, Harold B. Smith,
I. E. Moultrop, C. E. Stephens.

Finance Committee

C. E. Stephens, Chairman, Westinghouse E. & M. Co., 150 Broadway, New York, N. Y.
H. P. Charlesworth, E. B. Meyer.

Meetings and Papers Committee

A. E. Knowlton, Chairman, *Electrical World*, 10th Ave. & 36th St., New York, N. Y.
C. S. Rich, Secretary, 33 W. 39th St., New York, N. Y.
V. Bush, W. H. Harrison,
W. S. Gorsuch, C. E. Skinner,
T. A. Worcester.

Chairman of Committee on Coordination of Institute Activities, *ex-officio*.
Chairmen of Technical Committees, *ex-officio*.

Publication Committee

W. S. Gorsuch, Chairman, 600 W. 59th St., New York, N. Y.
H. P. Charlesworth, A. E. Knowlton,
F. L. Hutchinson, E. B. Meyer.

Committee on Coordination of Institute Activities

H. P. Charlesworth, Chairman, 463 West St., New York, N. Y.
W. S. Gorsuch, Everett S. Lee,
F. L. Hutchinson, E. B. Meyer,
A. E. Knowlton, C. E. Stephens.

Board of Examiners

H. W. Drake, Chairman, Western Union Telegraph Co., 60 Hudson St., New York, N. Y.
H. A. Currie, R. H. Marriott,
H. Goodwin, Jr. L. W. W. Morrow,
S. P. Grace, A. L. Powell,
A. H. Kehoe, W. R. Smith,
H. A. Kidder, S. D. Sprong,
R. H. Tapscott.

Sections Committee

Everett S. Lee, Chairman, General Electric Co., Schenectady, N. Y.

W. B. Kouwenhoven,
W. S. Rodman,
I. M. Stein,
W. H. Timbie

Chairmen of Sections, *ex-officio.*

Committee on Student Branches

W. H. Timbie, Chairman, Massachusetts Institute of Technology, Cambridge, Mass.

Herbert S. Evans,
F. O. McMillan,
Charles F. Scott,
W. J. Seeley.

Student Branch Counselors, *ex-officio.*

Membership Committee

J. Allen Johnson, Chairman, Room 302, Electric Building, Buffalo, N. Y.

Vice-Chairmen

E. P. Coles,
D. I. Cone,
Herbert B. Dwight,
E. F. Gehrkens,
James Harrison,
C. R. Jones,
R. L. Kirk,
T. G. LeClair,
D. W. Proebstel,
E. M. Wood.

Ex-officio

Chairmen of Section Membership Committees.

Headquarters Committee

R. H. Tapscott, Chairman, 124 E. 15th St., New York, N. Y.

F. L. Hutchinson,
C. E. Stephens.

Law Committee

E. B. Meyer, Chairman, 70 Park Place, Newark, N. J.

C. O. Bickelhaupt,
H. A. Kidder,
L. F. Morehouse,
W. I. Slichter.

Public Policy Committee

Bancroft Gherardi, Chairman, 195 Broadway New York, N. Y.

C. C. Chesney,
F. B. Jewett,
Farley Osgood,
Harris J. Ryan,
R. F. Schuchardt,
Harold B. Smith.

Standards Committee

F. D. Newbury, Chairman, Westinghouse E. & M. Co., East Pittsburgh, Pa.

C. M. Gilt,
C. R. Harte,
A. M. MacCutcheon,
J. F. Meyer,
V. M. Montsinger,
L. T. Robinson,
C. E. Skinner,
W. I. Slichter.

Ex-officio

Chairmen of Working Committees.

Chairmen of A. I. E. E. delegations on other standardizing bodies.

President of U.S. National Committee of I. E. C.

Edison Medal Committee

Appointed by the President for term of five years.

(Terms expire July 31, 1931)
John W. Howell,
L. F. Morehouse,
David B. Rushmore.

(Terms expire July 31, 1932)
H. P. Charlesworth,
Paul M. Lincoln,
C. E. Skinner.

(Terms expire July 31, 1933)
D. C. Jackson, Chairman.
C. F. Harding,
F. A. Scheffler.

(Terms expire July 31, 1934)
L. W. W. Morrow,
W. S. Rugg,
R. F. Schuchardt.

(Terms expire July 31, 1935)
C. I. Burkholder,
F. A. Gaby,
Harris J. Ryan.

Elected by the Board of Directors from its own membership for term of two years.

(Terms expire July 31, 1931)
J. Allen Johnson,
E. B. Meyer,
A. M. MacCutcheon.

(Terms expire July 31, 1932)
A. E. Knowlton,
Harold B. Smith,
R. H. Tapscott.

Ex-officio

William S. Lee, President,
W. I. Slichter, National Treasurer.
F. L. Hutchinson, National Secretary.

Lamme Medal Committee

(Terms expire July 31, 1931)
Charles F. Scott, Chairman.
H. H. Barnes, Jr.,
N. W. Storer.

(Terms expire July 31, 1932)
H. P. Charlesworth,
C. C. Chesney,
R. B. Williamson.

(Terms expire July 31, 1933)
Ralph D. Mershon,
Julian C. Smith,
Percy H. Thomas.

Committee on Code of Principles of Professional Conduct

Frank B. Jewett, Chairman, 195 Broadway, New York, N. Y.

A. H. Babcock,
G. Faccioli,
Harris J. Ryan,
R. F. Schuchardt,
C. E. Stephens,
John B. Whitehead.

Committee on Award of Institute Prizes

A. E. Knowlton, Chairman, *Electrical World*, 10th Ave. & 36th St., New York, N. Y.

L. W. Chubb,
W. S. Gorsuch.

Committee on Safety Codes

A. W. Berresford, Chairman, 420 Lexington Ave., New York, N. Y.

F. V. Magalhaes, Vice-Chairman.

A. E. Bettis,
J. C. Forsyth,
H. B. Gear,
F. D. Knight,
M. G. Lloyd,
Wills Maclachlan,
R. W. E. Moore,
John D. Noyes,
F. A. Pattison,
H. R. Sargent,
H. R. Searing,
H. S. Warren.

Committee on Columbia University Scholarships

W. I. Slichter, Chairman, Columbia University, New York, N. Y.

Francis Blossom,
H. C. Carpenter.

Committee on the Engineering Profession

H. A. Kidder, Chairman, 600 W. 59th St., New York, N. Y.

J. P. Alexander,
T. F. Barton,
B. M. Brigman,
H. P. Charlesworth,
L. F. Leurey,
L. W. W. Morrow,
John C. Parker,
John R. Price,
Herbert S. Sands,
M. R. Scharff,
H. H. Schoolfield,
W. I. Slichter,
J. B. Thomas.

Advisory Committee to the Museums of the Peaceful Arts

J. P. Jackson, Chairman, N. Y. Edison Co., 130 E. 15th St., New York, N. Y.

C. O. Bickelhaupt,
Randolph H. Nexsen.

Committee on Popular Science Award

A. E. Knowlton, Chairman, *Electrical World*, 10th Ave. & 36th St., New York, N. Y.

H. P. Charlesworth,
C. E. Stephens.

TECHNICAL COMMITTEES

Automatic Stations

F. Zogbaum, Chairman, N. Y. Edison Co., 4 Irving Place, New York, N. Y.

Chester Lichtenberg, Secretary, General Electric Co., 6901 Elmwood Ave., Philadelphia, Pa.

F. F. Ambuhl,
L. D. Bale,
C. W. Colvin,
A. M. Garrett,
Joseph Hellenthal,
C. A. Mayo,
I. E. Moultrop,
M. E. Reagan,
O. J. Rotty,
Garland Stamper,
D. W. Taylor,
L. J. Turley.

Communication

G. A. Kositzky, Chairman, Ohio Bell Telephone Co., 750 Huron Road, Cleveland, Ohio.

H. S. Osborne, Vice-Chairman.

H. M. Bascom,
G. R. Benjamin,
B. K. Boyce,
A. F. Brooks,
W. H. Capen,
J. L. Clarke,
R. N. Conwell,
B. R. Cummings,
H. W. Drake,
R. D. Evans,
C. E. Fleager,
D. H. Gage,
S. P. Grace,
Erich Hausmann,
H. L. Huber,
C. F. King, Jr.,
R. H. Manson,
John Mills,
J. W. Milnor,
J. L. Niesse,
F. A. Raymond,
H. A. Shepard,
H. S. Sheppard,
A. N. Symes,
H. M. Turner,
F. A. Wolff.

Education

W. R. Work, Chairman, Carnegie Institute of Technology, Pittsburgh, Pa.

M. W. Alexander,
E. W. Allen,
J. W. Barker,
Edward Bennett,
P. S. Biegler,
H. W. Buck,
R. F. Chamberlain,
C. R. Dooley,
H. E. Dyche,
O. J. Ferguson,
H. H. Henline,
E. A. Loew,
A. H. Lovell,
H. S. Osborne,
H. W. Price,
W. S. Rugg,
W. T. Ryan,
R. F. Schuchardt,
G. B. Thomas,
W. H. Timbie,
W. E. Wickenden.

Electrical Machinery

Philip L. Alger, Chairman, General Electric Co., Schenectady, N. Y.

E. B. Paxton, Secretary, General Electric Co., Schenectady, N. Y.

L. F. Adams,
B. L. Barns,
W. M. Dann,
H. B. Dwight,
C. M. Gilt,
T. T. Hambleton,
A. L. Harding,
C. F. Harding,
S. L. Henderson,
L. F. Hickernell,
J. Allen Johnson,
H. C. Louis,
A. M. MacCutcheon,
O. K. Marti,
V. M. Montsinger,
E. L. Moreland,
F. D. Newbury,
R. W. Owens,
A. M. Rossman,
R. B. Williamson,
H. L. Zabriskie.

Electrochemistry and Electrometallurgy

P. H. Brace, Chairman, Westinghouse E. & M. Co., East Pittsburgh, Pa.

Lawrence Addicks,
T. C. Atchison,
Farley G. Clark,
S. K. Colby,
J. C. Hale,
F. C. Hanker,
W. E. Holland.
F. A. Lidbury,
R. G. Mansfield,
J. A. Seede,
C. E. Sisson,
H. Speight,
Magnus Unger,
G. W. Vinal,
J. B. Whitehead,
E. A. Williford,
J. L. Woodbridge,
C. D. Woodward.

Electric Welding

P. P. Alexander, Chairman, General Electric Co., River Works, West Lynn, Mass.

C. A. Adams,
A. M. Candy,
Alexander Churchward,
S. Dushman,
F. M. Farmer,
H. M. Hobart,
C. J. Holslag,
J. E. Kearns,
J. C. Lincoln,
Ernest Lunn,
B. T. Mottinger,
J. W. Owens,
J. Slepian,
William Spraragen.

Electrophysics

O. E. Buckley, Chairman, 463 West Street, New York, N. Y.

W. S. Gorton, Secretary, 463 West Street, New York, N. Y.

V. Bush,
W. G. Cady,
W. F. Davidson,
C. L. Fortescue,
W. B. Kouwenhoven,
G. M. J. Mackay,
K. B. McEachron,
L. W. McKeehan,
H. Nyquist,
W. S. Rodman,
J. Slepian.

Liaison Representatives of American Physical Society:

Professor Leigh Page,
Dr. W. F. G. Swann.

General Power Applications

C. W. Drake, Chairman, Westinghouse E. & M. Co., East Pittsburgh, Pa.

E. A. Armstrong,
James Clark, Jr.
J. F. Gaskill,
Clyde D. Gray,
John Grotzinger,
Fraser Jeffrey,
A. M. MacCutcheon,
H. A. Maxfield,
John Morse,
N. L. Mortensen,
A. M. Perry,
D. M. Petty,
F. O. Prior,
H. W. Rogers,
L. D. Rowell,
M. R. Woodward.

Instruments and Measurements

E. J. Rutan, Chairman, New York Edison Co., 92 Vandam St., New York, N. Y.

R. T. Pierce, Secretary, Weston Elec. Instrument Corp., 578 Frelinghuysen Ave., Newark, N. J.

H. S. Baker,
P. A. Borden,
H. B. Brooks,
O. J. Bushnell,
A. L. Cook,
E. D. Doyle,
Melville Eastham,
R. C. Fryer,
J. B. Gibbs
W. N. Goodwin, Jr.,
I. F. Kinnard,
O. A. Knopp,
A. E. Knowlton,
H. C. Koenig,
W. B. Kouwenhoven,
F. A. Laws,
E. S. Lee,
Paul MacGahan,
W. J. Shackelton.

Applications to Iron and Steel Production

A. C. Cummins, Chairman, Carnegie Steel Co., Duquesne, Pa.

F. B. Crosby,
M. M. Fowler,
S. L. Henderson,
A. M. MacCutcheon,
A. G. Pierce,
F. O. Schnure,
W. B. Shirk,
G. E. Stoltz,
Wilfred Sykes,
T. S. Towle,
H. A. Winne.

Production and Application of Light

George S. Merrill, Chairman, Nela Park, Cleveland, Ohio.

J. W. Barker,
A. E. Bettis,
W. T. Blackwell,
H. S. Broadbent,
J. M. Bryant,
W. T. Dempsey,
E. E. Dorting,
L. A. Hawkins,
H. H. Higbie,
W. C. Kalb,
C. L. Kinsloe,
R. D. Mailey,
P. S. Millar,
C. J. Stahl,
G. H. Stickney.

Applications to Marine Work

R. A. Beekman, Chairman, General Electric Co., Schenectady, N. Y.

H. F. Harvey, Vice-Chairman.

J. Y. Wilson, Secretary, American Bureau of Shipping, 24 Old Slip, New York, N. Y.

Edgar C. Alger,
H. C. Coleman,
E. M. Glasgow,
C. J. Henschel,
Wm. Hetherington, Jr.,
H. L. Hibbard,
J. E. Kearns,
A. Kennedy, Jr.,
J. B. Lunsford,
I. H. Osborn,
G. A. Pierce,
W. H. Reed,
Edgar P. Slack,
H. M. Southgate,
W. E. Thau,
A. E. Waller,
Oscar A. Wilde,
R. L. Witham,
W. N. Zippler.

Applications to Mining Work

Carl Lee, Chairman, 20 North Wacker Drive, Chicago, Ill.

A. R. Anderson,
Graham Bright,
John H. Edwards,
Frank E. Fisher,
E. J. Gealy,
L. C. Ilsley,
J. E. Kearns,
W. H. Lesser,
D. E. Renshaw,
W. F. Schwedes,
F. L. Stone,
B. F. Tillson,
J. F. Wiggert.

Power Generation

F. A. Allner, Chairman, Lexington Building, Baltimore, Md.

J. R. Baker, Secretary, 1611 Lexington Building, Baltimore, Md.

F. A. Annett,
T. J. Bostwick,
J. B. Crane,
H. W. Eales,
N. E. Funk,
D. L. Galusha,
R. B. Gerhardt,
W. S. Gorsuch,
F. C. Hanker,
C. F. Hirshfeld,
F. H. Hollister,
A. H. Hull,
G. A. Jessop,
H. W. Leitch,
E. B. Meyer,
E. L. Moreland,
I. E. Moultrop,
G. E. Quinan,
F. A. Scheffler,
A. E. Silver,
W. F. Sims,
A. R. Smith,
E. C. Stone,
R. W. Stovel.

Power Transmission and Distribution

P. H. Chase, Chairman, Philadelphia Electric Co., 900 Sansom St., Philadelphia, Pa.

R. N. Conwell, Vice-Chairman.

E. T. J. Brandon,
C. I. Burkholder,
A. B. Campbell,
C. V. Christie,
O. G. C. Dahl,
Harold C. Dean,
L. L. Elden,
H. S. Evans,
R. D. Evans,
F. M. Farmer,
J. H. Foote,
L. F. Hickernell,
K. A. Hawley,
J. P. Jollyman,
A. H. Lawton,
L. L. Perry,
T. F. Peterson,
D. W. Roper,
A. E. Silver,
D. M. Simmons,
C. T. Sinclair,
L. G. Smith,
Philip Sporn,
C. F. Wagner,
H. S. Warren,
T. A. Worcester.

Protective Devices

Raymond Bailey, Chairman, Philadelphia Electric Co., 900 Sansom St., Philadelphia, Pa.

L. E. Frost, Secretary, Brooklyn Edison Co., 380 Pearl St., Brooklyn, N. Y.

J. E. Allen,
A. C. Cummins,
H. W. Drake,
W. S. Edsall,
W. W. Edson,
L. E. Frost,
E. E. George,
H. Halperin,
F. C. Hanker,
E. A. Hester,
L. F. Hickernell,
M. G. Lloyd,
J. P. McKearin,
H. A. McLaughlin,
A. M. Rossman,
A. H. Schirmer,
H. K. Sels,
H. P. Sleeper,
E. R. Stauffacher,
H. R. Summerhayes,
E. M. Wood,
H. B. Wood.

Research

L. W. Chubb, Chairman, W. E. & M. Co., East Pittsburgh, Pa.

H. D. Arnold,
Edward Bennett,
W. G. Cady,
E. H. Colpitts,
E. C. Crittenden,
W. F. Davidson,
W. P. Dobson,
F. M. Farmer,
J. Allen Johnson,
V. Karapetoff,
A. E. Kennelly,
J. K. McNeely,
F. W. Peek, Jr.,
Hubert H. Race,
C. W. Rice,
D. W. Roper,
T. Spooner,
J. B. Whitehead.

Transportation

Sidney Withington, Chairman, N. Y., N. H. & H. R. R. Co., New Haven, Conn.

Philip P. Ash,
Reinier Beeuwkes,
A. E. Bettis,
J. V. B. Duer,
H. H. Field,
Ira W. Fisk,
W. A. Giger,
K. T. Healy,
D. C. Jackson,
John Murphy,
Ivan Ofverholm,
H. Parodi,
W. B. Potter,
Ralph H. Rice,
A. S. Richey,
S. A. Spalding,
N. W. Storer,
W. M. Vandersluis.
Richard H. Wheeler,
R. P. Winton,
G. I. Wright.

INSTITUTE REPRESENTATIVES

Alfred Noble Prize Committee

A. E. Knowlton.

American Association for the Advancement of Science Council

O. J. Ferguson,
C. E. Skinner.

American Bureau of Welding

H. M. Hobart.

American Committee on Electrolysis

B. J. Arnold,
N. A. Carle,
F. N. Waterman.

American Engineering Council Assembly

A. W. Berresford,
C. O. Bickelhaupt,
F. J. Chesterman,
M. M. Fowler,
F. L. Hutchinson,
H. A. Kidder,
W. S. Lee,
William McClellan,
L. F. Morehouse.
I. E. Moultrop,

W. S. Rodman,
R. F. Schuchardt,
Charles F. Scott,
C. E. Skinner,
Harold B. Smith,
C. E. Stephens.
L. B. Stillwell,

American Marine Standards Committee

R. A. Beekman.

American Standards 'Association

F. D. Newbury,
John C. Parker,
L. T. Robinson.

H. H. Henline,
H. M. Hobart,
H. S. Osborne, Alternates.

American Year Book, Advisory Board

Henry H. Henline.

Charles A. Coffin Fellowship and Research Fund Committee

W. S. Lee.

Committee of Apparatus Makers and Users, National Research Council

C. E. Skinner.

Committee on Elimination of Fatigue, Society of Industrial Engineers

C. Francis Harding.

Committee on Heat Transmission, National Research Council

T. S. Taylor.

Engineering Foundation, Inc.

H. P. Charlesworth, H. A. Kidder,
G. L. Knight.

Engineering Societies Monographs Committee

E. B. Meyer, W. I. Slichter.

Engineering Societies Research Board

Gano Dunn, C. E. Skinner.

Hoover Medal Committee

Gano Dunn, F. B. Jewett,
E. W. Rice, Jr.

John Fritz Medal Board of Award

Bancroft Gherardi, R. F. Schuchardt,
W. S. Lee, Harold B. Smith.

Joint Committee on Welded Rail Joints

D. D. Ewing.

Joint Conference Committee of Founder Societies

The Presidents and Secretaries, *ex-officio*.

Library Board, Engineering Foundation, Inc.

Edward D. Adams, F. L. Hutchinson,
W. A. Del Mar, W. B. Jackson,
W. I. Slichter.

National Fire Protection Association, Electrical Committee

A. W. Berresford, F. V. Magalhaes,
Alternate.

National Fire Waste Council

A. W. Berresford, F. V. Magalhaes.

National Research Council, Engineering Division

F. B. Jewett, F. W. Peek, Jr.,
C. E. Skinner.
F. L. Hutchinson, *ex-officio*.

National Safety Council, Electrical Committee

A. S. S. E.—Engineering Section

A. W. Berresford.

Radio Advisory Committee, Bureau of Standards

A. E. Kennelly.

U. S. National Committee of th International Commission on Illumination

A. E. Kennelly, C. O. Mailloux,
Clayton H. Sharp.

U. S. National Committee of th International Electrotechnical Commission

GEOGRAPHICAL DISTRICT EXECUTIVE COMMITTEES

District	Chairman (Vice-President, A. I. E. E.)	Secretary (District Secretary)
No. 1—North Eastern	I. E. Moultrop, Edison Elec. Illum. Co., 39 Boylston St., Boston	A. C. Stevens, General Electric Co., Schenectady
No. 2—Middle Eastern	E. C. Stone, Duquesne Light Co., 435 Sixth Ave., Pittsburgh	J. A. Cadwallader, Bell Tel. Co. of Pa., 416 Seventh Ave, Pittsburgh
No. 3—New York City	H. P. Charlesworth, 463 West St., New York	C. R. Jones, Westinghouse E. & M. Co., 150 Broadway, New York
No. 4—Southern	W. S. Rodman, Box 675, University, Va.	J. S. Miller, Jr., Box 12, University, Va.
No. 5—Great Lakes	T. N. Lacy, Mich. Bell Tel. Co., 1365 Cass Ave., Detroit	A. G. Dewars, No. States Pr. Co., 15 S. 15th St., Minneapolis
No. 6—North Central	Herbert S. Evans, University of Colorado, Boulder, Colo.	M. S. Coover, University of Colorado, Boulder, Colo.
No. 7—South West	G. C. Shaad, University of Kansas, Lawrence, Kans.	Robert W. Warner, University of Kansas, Lawrence, Kans.
No. 8—Pacific	C. E. Fleager, Pac. Tel. & Tel. Co., 140 New Montgomery St., San Francisco	H. W. Hitchcock, 1050 Telephone Bldg., 740 South Olive St., Los Angeles
No. 9—North West	H. V. Carpenter, State College of Washington, Pullman, Wash.	R. D. Sloan, State College of Washington, Pullman, Wash.
No. 10—Canada	C. E. Sisson, Canadian Gen. Elec. Co., 1025 Lansdowne Ave., Toronto, Ont.	W. L. Amos, Hydro-Elec. Pr. Com., 190 University Ave., Toronto, Ont.

Note: Each District Executive Committee includes the chairmen and secretaries of all Sections within the District and the chairman of the District Committee on Student Activities.

LOCAL SECTIONS OF THE INSTITUTE

Name	District	Chairman	Secretary	Secretary's Address
Akron	2	H. C. Paiste	Alvin P. Regal	Phila. Rubber Works Co., Akron, Ohio
Atlanta	4	H. C. Uhl	O. O. Rae	Westinghouse E. & M. Co., Atlanta, Ga.
Baltimore	2	W. B. Kouwenhoven	J. Wells	Western Elec. Co., 25 Broening Rd., Baltimore, Md.
Birmingham	4		O. E. Charlton	Allied Engineers, Inc., Birmingham, Ala.
Boston	1	J. P. Kobrock	G. J. Crowdes	Simplex Wire & Cable Co., Sidney St., Cambridge, Mass.
Chicago	5	F. H. Lane	L. R. Mapes	Ill. Bell Tel. Co., 212 W. Washington St., Chicago, Ill.
Cincinnati	2	T. C. Reed	L. L. Bosch	Columbia Eng. & Mgt. Corp., 314 West 4th St., Cincinnati, Ohio
Cleveland	2	F. W. Braund	John M. Smith	Nela Park, Cleveland, Ohio
Columbus	2	C. D. Price	K. Y. Tang	Ohio State University, Columbus, Ohio
Connecticut	1	Samuel Ferguson	R. G. Warner	Yale Univ., 10 Hillhouse Ave., New Haven, Conn.
Dallas	7	L. T. Blaisdell	G. A. Dyer	Southwestern Bell Tel Co., Dallas, Texas
Denver	6	R. B. Bonney	N. R. Love	807 Tramway Bldg., Denver, Colo.

AFFILIATED STUDENT SOCIETY

Brown Engineering Society	Brown Univ., Providence, R. I.

ORDER FORM FOR REPRINTS OF PAPERS ABRIDGED IN THIS ISSUE OF "ELECTRICAL ENGINEERING"*

(January 1931)

Number	Author	Title
☐ **30-175**	S. Logan Kerr	Automatic Operator for Economy Control Applied to Hydroelectric Generator Stations
☐ **30-179**	F. W. Cartland	Lighting Airway Beacons Direct from High-Voltage Transmission Lines
☐ **30-180**	R. C. Buell, R. J. Caughey, E. M. Hunter and V. M. Marquis	Governor Performance During System Disturbances
☐ **30-185**	J. Elmer Housley	Lightning Investigation at Alcoa, Tenn.

***Members, Enrolled Students and subscribers are entitled to one complete copy of any paper abridged if it is requested within one year from date of its JOURNAL publication. Thereafter a charge of twenty-five cents per complete copy will obtain.**

Please order reprints by number. ***Address*** **Order Department A. I. E. E., 33 West 39th Street, New York, N. Y.**

Industrial Notes

Condit Offices in New Home.—The Condit Electrical Manufacturing Corporation has moved its sales and executive offices to the new administration building at Hyde Park, Mass.

Electrad Appoints Millard Van Blaricom.—The development of its amplifier business necessitating the enlargement of the technical staff, Millard Van Blaricom, expert in amplifying systems, has been appointed, according to a statement by Arthur Moss, president of Electrad, Inc., New York.

Westinghouse in Refrigeration Field.—Distribution of the Westinghouse refrigerator to all parts of the United States east of Kansas City will be begun at once, according to an announcement by Carl D. Taylor, manager of the refrigeration department of the Westinghouse Electric and Manufacturing Company. During 1930 the refrigerator has been distributed and sold in a gradually increasing area in the east.

Roebling Absorbs New Jersey Wire Cloth Company.—According to a recent announcement, the New Jersey Wire Cloth Company will cease its corporate existence on January 1, and the business will be continued by the John A. Roebling's Sons Company. The New Jersey Wire Cloth Company, now a subsidiary of the Roebling Company, manufactures wire cloth, wire netting, wire fences, etc., the sale of which will be continued through the parent company and other Roebling branches.

Grounding Devices.—Bulletin, 36 pp., "Principles of Grounding." Presents methods of grounding electrical apparatus and auxiliary equipment. A typical ground bus for an outdoor substation is illustrated, embodying recommendations of N. E. L. A. committees. Types of Burndy connectors for diverse applications are shown, as well as connectors used for copper or aluminum tube, cable or bar. Burndy Engineering Co., Inc., 230 East 45th Street, New York.

New G. E. Plastic Department.—The various plastic activities of the General Electric Company have been coordinated into one department known as the plastic department according to an announcement by Gerard Swope, president of the company. R. E. Coleman has been appointed manager of the new department with an advisory committee consisting of vice-presidents J. G. Barry, chairman, W. R. Burrows, and C. E. Eveleth. The new department will be responsible for sales, engineering and manufacturing of plastics and involves activities at the Pittsfield, Schenectady, Fort Wayne, Erie and Lynn (River) plants of the company.

New Power Amplifiers.—Electrad, Inc., 175 Varick Street, New York, has announced the addition of two newly perfected power amplifiers utilizing the revolutionary Loftin-White direct-coupled system which, with their model A-245, completes a line of amplifiers suitable for the present-day requirements of sound amplification of all types. These Electrad direct-coupled amplifiers are readily adaptable to all usual requirements of sound amplification from microphones, phonograph pickups, radio tuners—in fact for all types of amplification at audio frequencies.

NEMA Opposes One Form of Bids on Electrical Equipment.—Opposition to the practice of requiring detailed working drawings with bids on electrical equipment or as an element of contract, was expressed in a resolution adopted November 21 by the Executive Committee of the National Electrical Manufacturers Association. The resolution is as follows:

WHEREAS: The practice of requiring detailed working drawings with bids or as an element of contract is objectionable and works a hardship on the manufacturer in that there is involved not merely unnecessary expense, but the demand for information and data which are the result of knowledge and experience, and are major elements of the bidder's "Stock in trade," be it RESOLVED: That the National Electrical Manufacturers Association hereby records its formal opposition to the practice.

This opposition does not apply to such outline drawings of apparatus showing overall dimensions, assembly drawings of major components, wiring diagrams, performance data and other diagrams, charts, photographs and instructions as are needed for installation, operation and maintenance purposes.

Trade Literature

Illumination.—Booklet L. P. 102, 40 pp., entitled "Tendencies in Lighting Practice, 1930." Illustrated. General Electric Company, Nela Park, Cleveland, Ohio.

Steam Generating Equipment.—Catalog GC-6, 16 pp. Describes and illustrates the fuel burning and steam generating equipment manufactured by the Combustion Engineering Corporation, 200 Madison Avenue, New York.

Automatic Controller Valves.—Catalog 2002, 20 pp. Describes Bristol's automatic controller valves, motor operated types, including the latest developments for steam, water, air and gas. The Bristol Company, Waterbury, Conn.

The Coordination of Light and Music.—Bulletin L. P. 101, 24 pp. Describes the application of color lighting in motion picture theatres. General Electric Company, Nela Park, Cleveland, Ohio.

Fuse Meter Service Switch.—Bulletin 23, 4 pp. Describes Wadsworth accessible fuse meter switch with range and lighting circuits for new and old residence wiring. Wadsworth Electric Manufacturing Co., Inc., Covington, Ky.

Cars and Car Equipment.—Bulletin 1882, 32 pp. Describes and illustrates twenty-six types of street cars and buses placed in service within the last two years. Westinghouse Electric & Manufacturing Corporation, East Pittsburgh, Penna.

Ash Storage Tanks.—Bulletin, 16 pp. Describes vitrified glazed tile, ash storage tanks, providing complete facilities of ash storage for all types of ash conveyor systems. United Conveyor Corporation, Old Colony Building, Chicago, Ill.

Automatic Reclosing Equipment.—Bulletin 20508, 4 pp. Describes Westinghouse type FO-22 outdoor automatic reclosing equipment, designed for use on feeder circuits. Westinghouse Electric & Manufacturing Co., East Pittsburgh, Penna.

Tachometers.—Catalog 46, 16 pp. Describes Brown electric indicating and recording tachometers. These instruments consist of the indicating, recording or automatic control instrument, tachometer generator, wiring between generator and instrument. The generator can be connected to the driving shaft through gears, pulleys, chain or flexible coupling. The Brown Instrument Company, Philadelphia, Penna.

Small Motors.—Bulletin 1883, 16 pp. Describes the various types of Westinghouse small power motors. Illustrations show the construction details of the motors and some of their many applications. Another feature of this publication is a description of the sentinal breaker, a compact starting switch that provides overload protection for fractional horsepower motors. Westinghouse Electric & Manufacturing Co., East Pittsburgh, Penna.

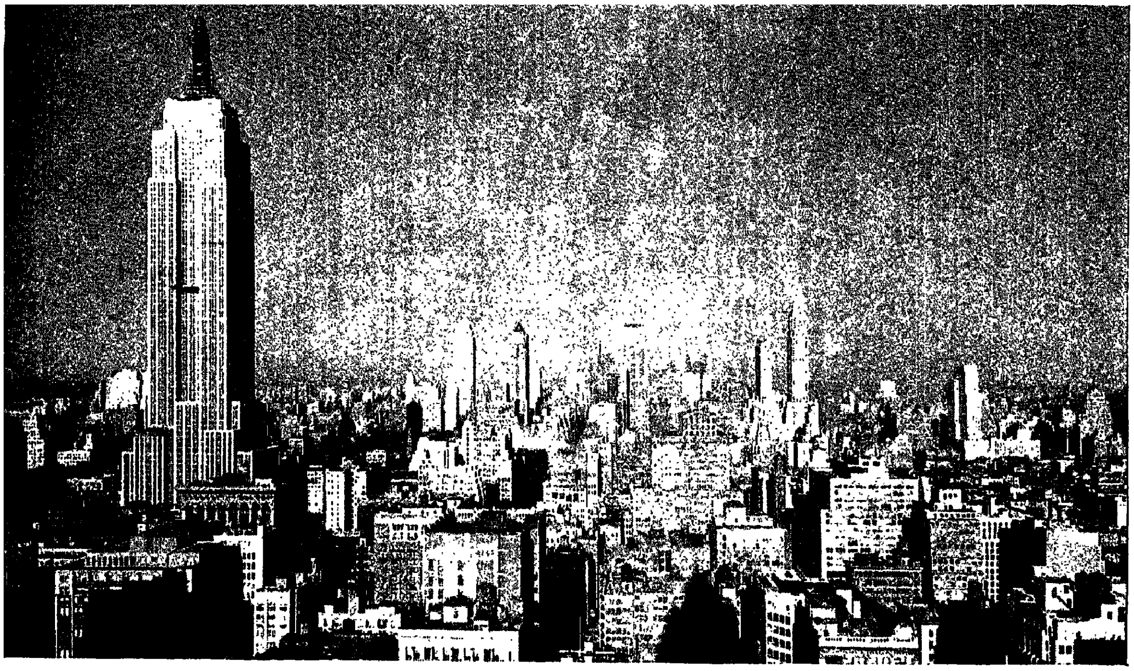
Dr. Arthur E.. Kennelly, professor emeritus of electrical engineering at Harvard University, past president A. I. E. E. (1896-1900), past president I. E. S. (1911), past president I. R. E. (1916), and well known both nationally and internationally for his versatility and untiring work for the betterment of the profession as applied to industry, comments further in this issue on the subject of internationally standardized magneti ccircuit units. *(See pages 133 and 141)*

W. S. Lee, president of the Institute, genial Southern gentleman, and conqueror of tremendous engineering undertakings, throws down the gauntlet in characteristic fashion in his declaration of "The Engineer's Duty to Himself and to the Public." Mr. Lee's wealth of engineering experience and his first-hand knowledge of men and affairs gives him a foundation from which to speak; his honest fearlessness enables him in an unimpassioned way to issue his challenge to his brother engineers. *(See page 125)*

D. C. Prince has made numerous discoveries and important contributions to the electrical engineering art. His studious application has carried him from a-c. motor developments to airplane machine gun design, and from radio engineering to mercury-arc rectifier research and design. His attention now is turned toward oil circuit breaker improvements. With the collaboration of W. F. Skeats he outlines important refinements in design which have led to the development of the oil-blast circuit breaker. *(See page 134)*

R. M. Stanley has been devoting his time and engineering talent to electrical utility design, operation, and economic problems for some twenty-three years. . He has been an aggressive leader in the promotion and adoption of engineering refinements in electric power equipment and has pioneered many of the paths now becoming familiar in the fields of remote control and automatic operation of major power producing and handling apparatus. One of his latest efforts is exemplified in the Ohio Falls hydroelectric generating station which he describes with the aid of E. D. Wood. *(See page 128)*



Winter Conventioners Viewed New York from its Newest Skyscraper, the 1,427-ft. Empire State Building (left).

ARAM BOYAJIAN for some time has been intimately associated with various phases of the stability problem as it involves electric power circuits and equipment. As a contributor to creative thought in this special field, Mr. Boyajian already has given considerable to active constructive debates at Institute gatherings. In this issue he discusses "The Physical Nature of Instability" in collaboration with O. P. McCarty. (*See page 110*)

MERCURY-ARC rectifiers, gradually gaining a position of importance in the power supply field, have been applied successfully in the strenuous service of subway transit lines. Howard M. Van Gelder, electrical engineer of the City Transit Department, Philadelphia, presents an interesting discussion of the application of mercury-arc equipment on that city's new subway system. Mr. Van Gelder has been more or less intimately associated with electric railway work for more than thirty years, dating back to the initial elevated railway electrification in New York City. (*See page 97*)

Electric Power *in the* Lumber Industry

From logging to the manufacture of finished products the lumber industry depends upon electric power, frequently manufacturing its own from sawmill refuse. The changing order of affairs both inside and outside of the industry now emphasizes fuel economy, places an increasing premium upon wood-waste, and makes by-product electric energy an important revenue producer.

By A. H. Onstad

Weyerhaeuser Timber Company
Tacoma, Washington

ADVANTAGES accruing from the use of electric energy for the distribution of power and for electric drive around a lumber manufacturing plant are many indeed. Prior to the adoption of electric power transmission a lumber plant had at least two, (and sometimes more) complete power plants on its premises, each with a full complement of boilers, engines, pumps, and other equipment as well as a full operating force. One of these plants served the sawmill, one served the planing mill, and sometimes one served a box factory or other side line; or some power user that could not be reached by belt or rope drive from the main sawmill power plant.

Development of the low-pressure and mixed-pressure turbine generators stimulated the early adoption of electric power distribution. With a mixed-pressure machine installed in the sawmill power house to take exhaust steam from the sawmill engine (which usually was a Corliss engine) and to take all the steam from the many steam cylinders throughout the mill, enough power could be generated to serve the planing mill and other departments without drawing much live steam from the boilers. The cost of such electric generating equipment, plus the cost of the electric drives in the planing mill, frequently exceeded the cost of a separate power plant to serve the planing mill; but the investment was justified by the reduction in operating force and in maintenance cost.

Considered only from the angle of fuel economy, electric power as applied to the lumber industry, except in a few isolated instances, had no advantage over any other power until within the last decade. The lumber industry has had such a superabundance of natural fuel in the wood waste from its operation, that loggers have been careful to send to the mill only such logs as would produce a high percentage of merchantable lumber. Under normal conditions the sawdust produced from the lumber cutting and finishing machines is enough, and often more than enough, to serve local power needs. Any additional wood waste at the mill must be burned in refuse burners, which are expensive to build and maintain, and which usually scatter partly burned particles of wood over a wide area with attendant evils.

Gradually, however, because of various changing of incidental conditions, the economic situation with regard to fuel in the lumber industry is changing; wood waste is being used more and more in the production of various "composition boards." Changes made in the method of lumber milling are increasing steadily the kilowatt-hour consumption per unit of lumber, which is reaching as much as 121 kw-hr. per 1,000 board-ft. in some mills that are carrying the manufacturing to a fine degree. This change also is increasing demand for process steam.

These and other changes along with the possibility of selling surplus power to public utilities or other power consumers are placing an ever-mounting value on mill refuse; hence, instead of wood refuse being the traditional liability around mills, at many plants it now has an appreciative monetary value. With a contract for the sale of surplus power, a milling company can run its generating equipment practically at 100 per cent load factor; and if it has sufficient electric generating equipment it can turn all of its mill waste into revenue. Thus it has become imperative that efficient power plant equipment for the conversion of waste products into power be installed within the lumber industry. Motor applications also are being made with ever increasing emphasis upon power conservation in addition to the continuing demand for continuity of service.

One noteworthy example is the recently completed steam-electric generating plant of the Weyerhaeuser Timber Co. at Longview, Wash. In this plant the electric generating equipment consists of two 7,500-kw., 0.8-power factor, 2.3-kv., three-phase, 60-cycle turbine-generator units. Steam is delivered to these units at 300-lb. gage pressure at the throttle and 580-deg. fahr. With the units operating at full load, 150,000-lb. of steam per hr. at a pressure of 125-lb. gage may be bled from each machine for use in the lumber drying kilns.

Two 500-kw., 250-volt, d-c. generators driven by

Presented at A. I. E. E. Southern District meeting, Louisville, Ky., Nov. 19-22, 1930. (No. 30-183.)

Two-speed double-motor (synchronous) band-mill drive with associated automatic-control apparatus; 400-hp., 600-rev. per min. and 250-hp., 514-rev. per min.

synchronous motors supply current for 27 cranes used for handling lumber, as well as direct current for other d-c. motors and for the exciting current for the synchronous motors.

Some 1,200 motors, not including motor-driven tools such as portable drills and grinders, motor-driven electrical welding sets, electric clocks, and motor-driven office appliances, aggregate 23,849 hp. These include:

71	2,200-volt synchronous motors	10,645 hp.
30	2,300-volt induction motors	2,875 hp.
1,021	550-volt induction motors	8,575 hp.
78	220-volt direct-current motors	1,754 hp.

The load on this power plant with its 23,849 connected hp. averages 7,000 kw. and by the use of synchronous motors the power factor of the load is kept at 0.96 leading.

In the woods, electric power is now being used in a limited way for driving portable saws for falling trees and bucking them into long lengths. These saws are chains with cutter teeth attached to one side of the links which run over two sprockets, one mounted at each end of the light steel frame holding the sprockets in position and forming a guide for the saw chain. A specially designed motor of about 5-hp. capacity geared to the driver sprocket furnishes the power, taking its energy from nearby transmission lines, or from small gas-driven generator sets which may supply power to several such saws working within a limited area.

Electric power also is being used in a limited way for "yarding and loading" logs. This is the operation of dragging the log from where it was cut out of the tree and loading it aboard the cars for shipment to the mill.

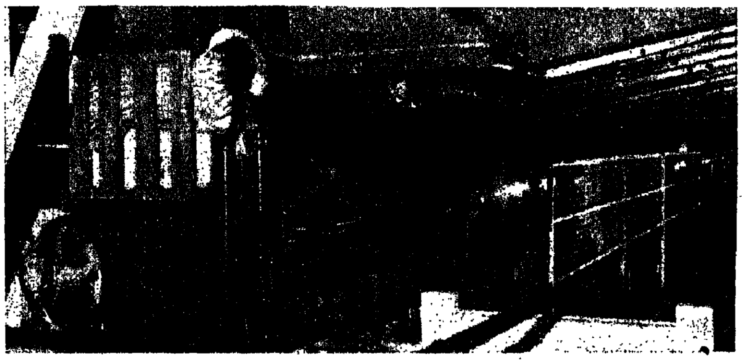
Equipment in use varies for various sections or growth of timber; on the Pacific slope of the Cascade Mountains where it is used to the greater extent, the equipment resembles heavy-duty hoisting equipment both in mechanical construction and in load characteristics.

The yarder is that part of the equipment that is used for dragging the log from the point where it has been cut out of the tree to the railroad siding for loading onto cars. Two full-load line speeds are provided, a high speed being 1,800 ft. per min. and the low speed being 900 ft. per min. The higher speed is used on the smaller logs and the lower speed for the heavier logs. This variation of speed is obtained through reduction gears of different ratios connected to the drum by friction clutches. The usual equipment is a 300-hp. wound-rotor motor having a wide range of speed control through secondary resistance. These motors are designed for a pull-out torque of approximately 300 per cent, but their service is such that frequently they are loaded to the stalling point.

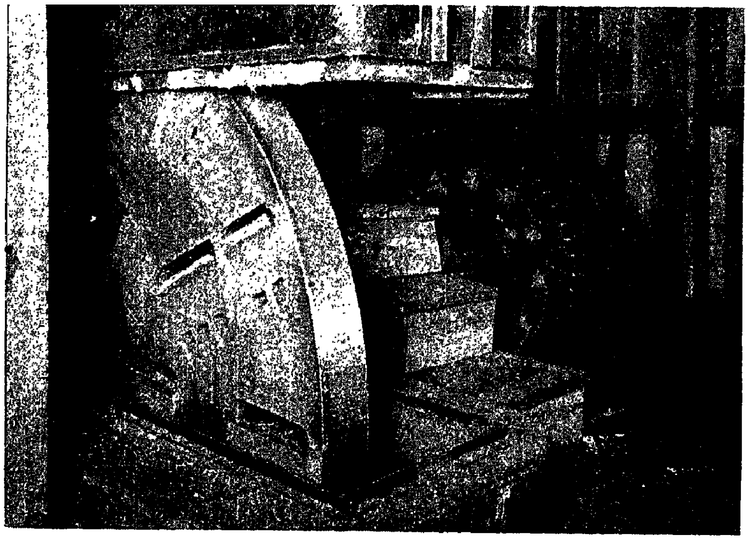
The loading end of this logging equipment usually consists of two 75- or 100-hp. wound-rotor motors. The hoisting line of the loading equipment passes through sheaves properly supported over the load. The usual procedure in loading a log is to fasten one hoisting line to each end of a log; the log can then be manipulated through these double hoists so that one end may be lowered onto the car ahead of the other to conform to the requirements of binding the logs into the load in such a way that they will arrive safely at their destination at the mill pond.

For a large operation on which load factor or days of operation per year is high, and in which life of operation is sufficiently long to permit of reasonable obsolescence charges, this has proved profitable.

One serious disadvantage to the use of electrical equipment for woods operation is the danger of loss of equipment by fire. The cost of electrical logging equipment is so great that the units are built only on order. The time required to replace a machine or repair one damaged by fire is therefore so great that it results in too severe a loss of production to warrant the adoption of electric power for logging operations except in a few special cases. Electric power for the propulsion of trains hauling logs out of the woods is being used in one or two instances, but insufficient tonnage on the average logging railroad prevents its general adoption even for this purpose.



A 250-hp. slip-ring motor driving a gang of trimmer saws



A typical 90-in. "hog" driven by a 400-hp. 600-rev. per min. synchronous motor. This machine reduces slabs and edgings to a refuse suitable for use in the furnaces

There is no specific rule governing the application of motor drive to sawmill machinery; power required for driving the various sections can be computed using the same laws that govern the application of electric drive to any other line of machinery. Before attempting to compute the motor requirements for these applications, however, one making these computations should be thoroughly familiar with the possible loading of the various sections to be driven. In applying motor drive to live rolls and transfer chains, the matter of obtaining sufficient starting torque is usually of prime consideration. The length of the roll trains and transfer tables is so short that if they are left in operation for a period of a minute or two they will completely unload all material that is on them.

Full-voltage across-the-line starters are used for all except wound-rotor and d-c. motors.

Selecting the proper starting equipment requires considerable thought, for with the frequent starting and stopping of the various sections, the duty imposed on the starting equipment is even more severe than that imposed on the motors. Maintenance men spend more time keeping the starting equipment in good operating condition than they do on the motors themselves.

There are many applications where thermal overload relays will not function if the doors of the cabinets enclosing the starting panels are left closed; this is due to the rise in temperature within the cabinets caused by the arc created in opening the motor circuit. Some of the transfer tables in the mill are started on an average of four or five times per minute.

One of the advantages of motor drive is the ease with which the machinery can be started and stopped, which permits running the machinery only through the period that it is actually engaged in moving lumber. As this in many cases is only a small fraction of the total working time of the shifts, considerable wear and tear of the machinery is prevented by stopping its movement when not actually needed.

Among recent applications of starting equipment that has proved worth while is the automatic starting and stopping trains of live rolls and transfer chains to permit the movement of lumber over them; for instance, a train of several sections of live rolls may be used for carrying timbers to the timber dock. As these timbers do not come with any degree of regularity, the rolls need operate only a small portion of the time, with a trip-pan arrangement placed between successive rolls throughout the length of the route. These trip-pans are mechanically connected to the starting stations of the motors driving the sections in such a manner that when the pan is depressed by the timber going over it, the motor is started and kept in operation until all of the pans in that train of rolls are free to rise to the "up" position. With such an arrangement each section of rolls is started as the timber approaches and automatically stops when the timber passes.

Adapting individual motor drive to the machinery of a lumber plant presents many perplexing problems; with few exceptions, the speed of the final drive of sawmill and wood-working machinery can be placed in two groups—a slow-speed group and a high-speed group.

Log hauls, transfer tables, and conveyors belong to the slow-speed group, with final speeds ranging from 1½ to 25 rev. per min. Live-roll drives ranging from 100 to 175 rev. per min. also can be placed in this class.

It was not until the so-called herringbone-type gear was developed and it became practical to build speed-reducing power transmissions of large reduction ratios that individual motor drive for these slow-speed groups became practical and economical. Now, reduction ratios of 150:1 with high efficiency may be obtained. This permits the use of motors of 1,200 to 1,800 rev. per min. to be used for practically every slow-speed drive, resulting in better electrical load characteristics and greater economy of installation.

Cutting speed for saws and the knife-type cutters of wood-working machines range from 8,000 to 14,000 ft. per min., which calls for speeds ranging from 300 to 7,200 rev. per min. These can be classed as high-speed drives. Mechanical connection between these and motors of economical speed characteristics did not present the difficult problems involved in the slow-speed drives.

Recent developments in planing mill machinery such as matchers, moulders, and saws, have opened a new field for the use of high-speed direct-connected motors. A large modern matcher has eight motors, totaling 270 hp., built into the machine. For these applications the machine manufacturers buy the rotor without a shaft and the stator without a frame and incorporate them in the construction of the machines. A modern matcher (commonly called a planer) has the following motors:

Service	No. Motors	Horsepower	Speed (r. p. m.)
Top cylinder	Two	40	3,600
Bottom cylinder	One	40	3,600
Outside side head	One	30	3,600
Inside side head	One	25	3,600
Top profiler	One	30	3,600
Bottom profiler	One	25	3,600
Feed work	One	40	1,200

As the cutter-head cylinders all turn in ball-bearings and are carefully balanced and heavy, they will continue to run for ten or fifteen minutes after the current has been cut off the motors. To make it possible to stop these quickly, the control is equipped for plugging service so that when it is necessary to stop a head or cylinder for any purpose the motor is plugged, bringing it to a stop in a few seconds.

Modern moulders are built for variable speeds of the spindle obtained by varying the frequency of the circuit by the use of frequency changers. For normal work the cylinders are equipped with six or eight knife cutters and usually operate at 3,450 rev. per min. For the exposed surfaces of the moulding requiring a finer finish the particular heads used for this exposed surface are speeded up (by changing the frequency) to 6,000 or 7,200 rev. per min. Control equipment is so arranged that the speed of any one or all of the five cutter heads or cylinders of the moulder may be increased.

Synchronous motors range in size from 50 hp. to 400 hp. and in speed from 225 to 1,800 rev. per min. Two types of loads are selected for synchronous-motor drive; (1) widely fluctuating loads having a low load factor, such as bandmills, edgers, slasher, trimmers and hogs; and (2) large loads of high load factors such as fans, pumps, and air compressors. Synchronous motors are not used on drives that require frequent starting.

All synchronous motors are wound for 0.8 factor and have a pull-in torque of 100 per cent of full-load torque. All synchronous motors are started with automatic, full-voltage, across-the-line starters and with few exceptions are all excited from the 250-volt buses or feeders that supply power to the cranes and other d-c. motors throughout the plant. Synchronous motors located so far from the d-c. lines that the cost of a d-c. circuit to the motor for excitation would be nearly as much as an exciter are equipped with direct-connected exciters.

Synchronous motors have proved very satisfactory for widely fluctuating loads, the application to driving "hogs" being a striking example. Motors of 250 hp. at 600 and 720 rev. per min. and 400 hp. at 600 rev. per min. are used for this, and have field control relays so adjusted that when the motor pulls out of step because of overload, the field excitation is cut out, and automatically restored when the motor again approaches synchronous speed. This may occur as many as 100 times during an eight-hour shift.

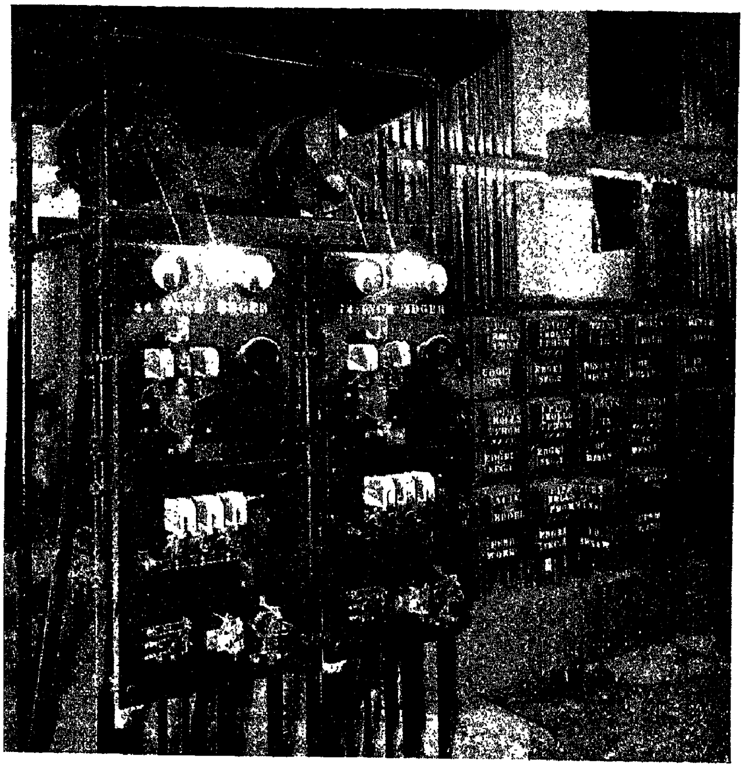
The 2,300-volt induction motors range in size from 50 to 250 hp. These are mostly wound-rotor motors driving machinery requiring frequent starting, or machinery which will not permit the severe strains imposed on it by full-voltage across-the-line starting. Some equipment requires limited speed control and for this purpose the wound-rotor motor and drum controller are both used. Induction motors of 50 hp. and smaller ratings are wound for 550 volts.

Except in sizes of 7½ hp. and smaller, the 550-volt induction motors are of the so-called double-wound-rotor type. These have the starting characteristics of the high-resistance-rotor motor and the running characteristics of the squirrel-cage motors.

One unusual motor application is that employed for driving the main bandsaw. For the regular run of fir logs a saw speed of 10,500 ft. per min. is the ideal speed; but for a certain species of fir log a saw speed of 8,000 ft. per min. is the most practical. As the logs requiring slow-speed sawing are mixed promiscuously with the softer logs, the custom has been to saw them all with the higher-speed saw. This has resulted in erratic sawing of the hard logs. At the Longview mill practically instantaneous speed changes from 10,500 to 8,400 ft. per min. are arranged for. This was accomplished by putting two synchronous motors on one motor base, driving the same pulley with the shafts rigidly coupled together. A 400-hp. 600-rev. per min. motor was installed as the main motor to use in starting the bandmill and for sawing the average run of logs. The other motor was a 250-hp. 450-rev. per min. motor. While the large motor is used for furnishing the power the small motor is disconnected from the line so that the only power required to drive it is that necessary to overcome windage losses. When a hard log is sawn the sawyer, by pressing two push-buttons, disconnects the large motor from the line and connects the small motor, which drops the speed of the saw to 8,400 ft. per min. The change from one speed to the other is made as frequently as the sawyer deems necessary.

Another unusual application of electrical power t sawmill machinery is in driving the feed works of the larger edgers, the machines that rip the boards and timbers into the desired widths. The edger arbor on which the saws are mounted is direct-connected to a 400-hp., 0.8-power factor, 1,200-rev. per min. synchronous motor. The feed rolls that feed the stock into

A modern high-speed planter; 9 of its 13 motors, varying from 2 to 75 hp., are shown



Typical arrangement of starting panels; automatic across-the-line synchronous-motor starters in the foreground

the edger are driven by a 10-hp. series motor through reduction gears and chain drive. These are so proportioned that with no load on the motors the surface speed of the rolls will pull the lumber into the edger as rapidly as good work can be done with the saws. As larger and thicker pieces are sent through the edger the load on the feed works motor increases and automatically slows the feed. Speed characteristics of the 10-hp. motor are such as to provide automatically the proper rate of feed into the saws for the varying thickness of material being sawn.

Among unusual applications of electric power to sawmill machinery is that used by the Weyerhaeuser Timber Company at Mill "C," Everett, Washington. This mill, located approximately three-quarters of a mile away from the power plant, is equipped with individual motor drive throughout, but differs from the usual mill in the respect that no steam is used in the mill for any purpose. The cost of a well-constructed steam line was such that it was decided to use compressed air in place of steam for operating all lifting cylinders, loaders, niggers, etc. A two-stage air compressor, having a capacity of 1,500 cu. ft. of free air per min., driven by a 250-hp. synchronous motor, furnishes all of this compressed air.

For driving the sawmill carriage a slow-speed, d-c., traction-type elevator motor was used, specifications calling for a torque of 12,500 lb. rather than the conventional horsepower rating. Power for this motor is taken from a motor-generator set consisting of a 75-hp., three-phase motor driving two d-c. generators; one to furnish current to the armature of the motor and a smaller one to furnish current for exciting the fields of the generator and the motor. Accurate and quick speed control of the carriage is achieved through a Ward Leonard system which has proved highly satisfactory in every respect.

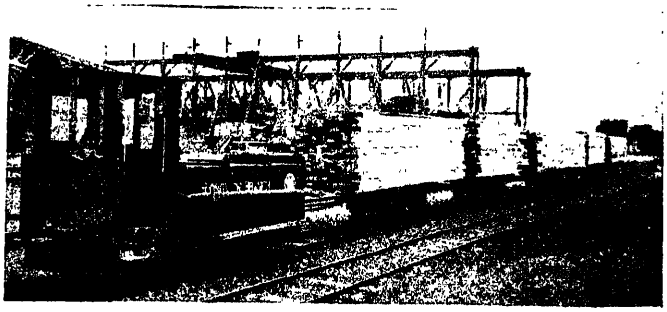
Armature leads of the motor are connected directly to the armature terminals of the generator, with the full field left on the motor at all times. Hence, speed control is effected by varying the voltage of the generator through field resistance placed in the field circuit of the generator. Reversal of the motor is effected by reversing the fields of the generator. This motor is connected to the carriage through wire ropes, one end of which is securely fastened to the carriage, the other end being fastened to a 30-in. sheave on the motor shaft. The cycle of operation is two revolutions in one direction and then two revolutions in the opposite direction, at a normal rate of from seven to thirteen cycles per min. Because the motor does not set up any windage through the coils by its own revolutions, it was necessary to provide artificial ventilation. This was accomplished by enclosing the motor in a galvanized iron housing through which cool air is forced by a motor-driven fan.

The most recent application found for electricity in the sawmill industry incorporates a Taglibue-Heppenstal moisture indicator. This consists of a case in which is mounted a battery, amplifying tubes and transformers, and an ammeter. Long, flexible leads from this cabinet are connected to two sharp terminals in a small portable handle that the lumber tester carries with him when inspecting lumber. When the points are driven into a piece of wood a current is set up and the value of this current is calibrated as the percentage moisture content of the wood. This method of testing

A double-squirrel-cage, 7.5-hp., 1,200-rev. per min., 550-volt induction motor direct-connected to conveyor drive for "dryness of lumber" has proved so dependable that it now is a standard for testing lumber that is bought with specification calling for a definite moisture content.

Storage-battery locomotives usually of seven-ton capacity having 225-ampere-hour batteries are used for the transportation of lumber from one department to another, where these departments are so arranged that transportation cannot be readily accomplished by crane service. These locomotives run on a 30-in. track, pulling four-wheel roller-bearing industrial cars with train loads as great as 60 tons. They stay in service for eight-hour shifts without recharging of the battery. Small storage-battery trucks and lift trucks are used in some departments for stacking certain items of lumber and for short-distance movement of lumber.

With modern industrial lighting units it is possible to provide illumination so suited to the work that production can be carried on at night with as high a rate of efficiency as that obtained during daylight operation.



A 7-ton battery locomotive in mill yard service

Power required in kilowatt-hours per 1,000 ft. of lumber sawed varies over a wide range, depending upon the sizes of the finished product and the completeness with which the manufacture is carried on.

At a large recently constructed fir mill the power required amounts to 34 kw-hr. per 1,000 ft. of lumber through the mill when sawing the sizes commonly encountered in ordinary construction. The total power consumption of the mill in question amounts to 80 kw-hr. per 1,000 ft. of lumber, including the power required for sawing, for fans at the dry kiln, for planing, and for transportation.

Another large plant handling both pine and fir and producing lumber of various standard sizes shows an over-all power consumption of 78.5 kw-hr. per 1,000 ft. of lumber produced divided as follows:

TOTAL KW-HR. PER 1,000 FT.

Sawmill	26.6
Planing mill	14.9
Dry kilns	24.5
Lighting and transportation	12.5
Total	78.5

Mercury Rectifiers for Subway Service

Simplification in station design, construction, and operation results from use of mercury arc rectifiers and metal-clad switchgear and bus units; ventilation and noise problems easier to cope with; 9,000-ampere load swings handled by single unit.

By H. M. Van Gelder
Electrical Engineer,
Department of City Transit,
Philadelphia
Member A. I. E. E.

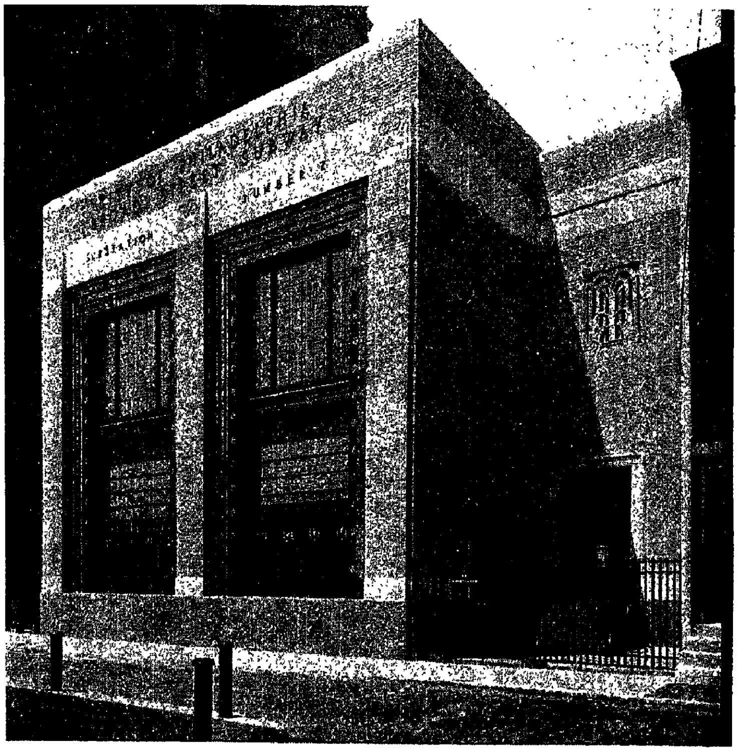
DEPARTING from previously established practise, the Philadelphia Department of City Transit has installed in its most recent substation, mercury arc rectifiers instead of the synchronous converters as installed at its other three substations. This change in equipment selection was brought about partly by recent improvements and developments in rectifier equipment, and partly because some difficulty had been experienced with the synchronous converters flashing over with extreme load variations. Other influencing factors included the better efficiency of the rectifier at light loads, the absence of large rotating parts with their attendant troubles and noise, the absence of commutation of heavy current, better stability under short-circuit conditions, and the relative simplicity of bringing them on the line for service.

Initial construction of Philadelphia's Broad Street subway was started in 1924 and the first six-mile section extending northward from the City Hall was placed in operation in 1928. Initial construction will accommodate four tracks, but at present only two local tracks are installed and in service. To serve this first section, three 6,000-kw., synchronous-converter substations (each containing two 3,000-kw. units—one as a spare) were built at convenient points and of sufficient size to accommodate equipment to serve the expected ultimate subway development.

An extension of the Broad Street subway south from the City Hall, a distance of about three-quarters of a mile, necessitated the construction of a fourth substation to serve an immediate demand for traction power and to serve as a basis for further extension. Experience obtained through two years' operation of the six-mile North Broad Street unit of the subway, indi-

---

From "Substations of the Broad Street Subway of Philadelphia," (No. 30-173) presented at the A. I. E. E. Middle Eastern District meeting, Philadelphia, Oct. 13-15, 1930.



Substation architectural treatment is in keeping with surroundings

cated by short-time peak loads, would determine the capacity of rectifier units and that such peaks usually lasted less than ten seconds, or during the multiple motor operation on notching acceleration. Consequently the 300 per cent load rating was reduced from a three-minute limit to a one-minute limit, and a unit having a continuous rating of 4,000 amperes at 630 volts, 6,000 amperes at 612 volts for two hours, and 12,000 amperes at 550 volts for one minute, was decided upon. Two units have been installed, one to serve as a spare. The present building will accommodate four units.

Regulation of these rectifiers closely approximates that of the synchronous converters in the original substations, thus making it possible for the two types of substations to be operated in parallel even for extreme fluctuations of load. It is not intended to install both converters and rectifiers in one substation for parallel operation; and there is no necessity for it.

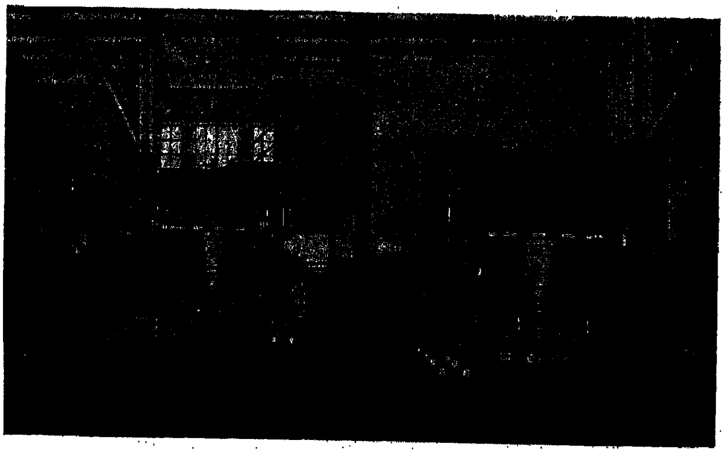
Rectifiers are water-cooled, double six-phase units, containing 12 anodes and equipped with automatic a-c. ignition and excitation, automatic water control, and an indicating vacuum regulator which controls the rotary pump according to predetermined vacuum points. This vacuum regulator also removes the rectifier from service if the vacuum falls before a predetermined value. Thermometers with electrical contacts provide the necessary thermal protection for each rectifier unit. Serving each unit there is a static mercury vacuum pump and two rotary oil vacuum pumps, one of which is a spare. The spare pump was specified as an extra precaution against possible failure of the one piece of rotating apparatus involved in the substation. Operating experience has shown that this rotary pump operates not more than 25 per cent of the time under present conditions.

The only cooling water required for the substation is for the rectifiers and the supply for this service is taken from two different city mains to insure availability of continuous supply. Because of the relatively light continuous load and the prevailing low cost of water, it has been found to be cheaper to waste the water than to provide cooling equipment for its re-circulation.

Transformer cells or rooms are provided at each of the four corners of the building, an arrangement which permits each transformer cell to have two outside openings at ground level and a large individual ventilator in the roof. One of the ground-level openings contains adjustable louvers and the other has a vertical lift door which gives entrance from the street; thus natural ventilation from two directions is provided. Since noise is practically completely absent from the equipment of this substation, no special precautions had to be observed in connection with sound-proofing and no special ventilating problems were involved.

Another departure in design in this substation was the use of an armor-clad bus and switchgear structure affording complete circuit accommodation for the incoming 13.8-kv. circuits, bus, oil circuit breakers, instrument transformers, disconnecting devices, etc. All cable leads to and from the armor-clad structure are lead-covered and wiped permanently to potheads which form a part of the structure itself. One attractive feature of this type of equipment is that all relays and connections are self-contained and mounted on the various switchgear units. Also, each armor-clad structure is completely built and assembled in the factory, requiring no masonry structure in the station except for foundation blocks; this simplifies both station design and station construction.

The subway d-c. power demand is of such a fluctuating character and, at present, has such a low sustained value that it was found of little use in forming or baking-



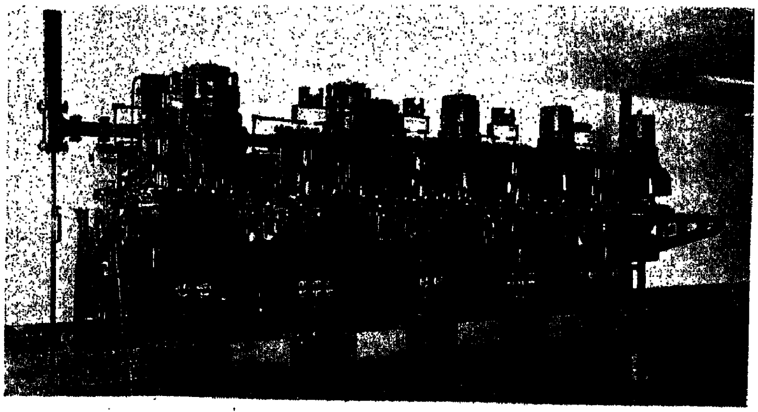
Two 4,000/12,000-ampere rectifiers in subway service; one a spare out the rectifier. To furnish a continuous load for this purpose a water rheostat which will absorb 1,200 amperes has been installed to operate in parallel with the traction load. If necessary, the rectifier can be operated six-phase or three-phase at times of bake-out to increase the current per anode.

All apparatus in the substation is controlled from the main switchboard in an operating office on the rectifier floor. All other switchboards and all 630-volt d-c. circuits are in the basement. The d-c. connections from the cathode of the rectifier pass directly through the floor to the rectifier switchboard below. This board contains a remote-control positive switch and a special quick-acting circuit breaker for each rectifier, with auxiliary switches and interlock so arranged that when the 13.8-kv. oil circuit breaker of the rectifier unit is closed, all other starting functions are performed automatically. Thus the operator has only to close the positive d-c. circuit breaker control switch to bring the rectifier on the bus.

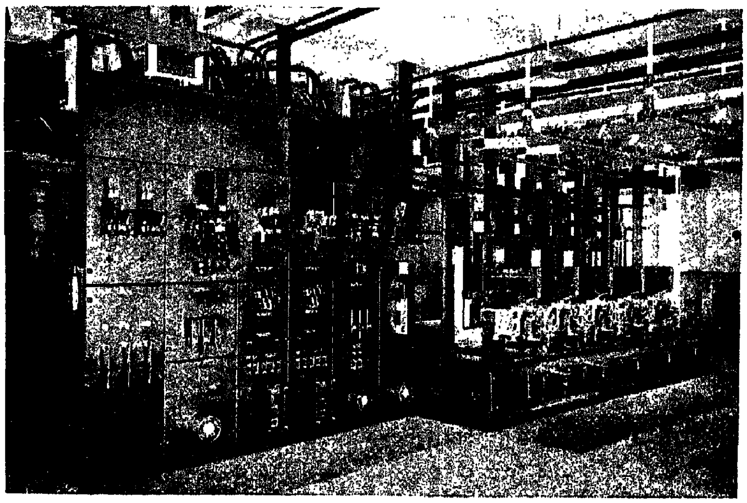
The four neutral connections of each main transformer are carried to the basement through wall ducts to its interphase transformer located immediately adjacent to the negative bus. The neutral lead of this interphase transformer constitutes the negative connection of the rectifier nuit and is connected to the negative bus.

From the rectifier switchboard in the basement the main 630-volt positive circuit runs directly to the positive bus; thence through the high-speed circuit breakers to the feeder switchboard and out through underground cables and conduits to the air circuit breakers and contact rail in the subway. Thus, all 630-volt power circuits are kept off the main floor. Furthermore, all of these circuits are run in the basement by means of copper bars, no cable being used until the outgoing underground cables are reached.

The station auxiliary switchboard in the basement has its principal operating circuits controlled from the main control board in the operating office. A 125-volt storage battery supplies energy for the control circuits while the auxiliary a-c. circuits for the rectifier units have three separate sources of power to insure continuity of service—an auxiliary station transformer fed from the 13.8-kv. main bus, and a second auxiliary transformer fed from either of two 4.6-kv. lighting feeders brought into the station from different power sources.



Metal-clad switchgear units simplify construction, operation, and maintenance



Rectifier switchboard and high-speed breakers in Philadelphia substation

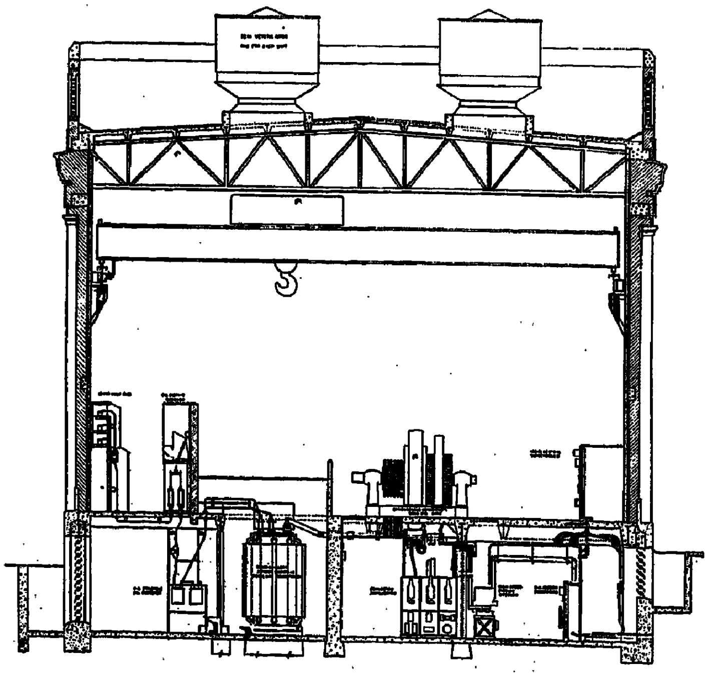
Since it was placed in operation April 20, 1930, this heavy-duty rectifier installation has functioned satisfactorily. During early operation a few back-fires occurred doubtlessly due to insufficient baking-out of the rectifier before heavy overloads were carried. However, no damage was done and now loads of 10,000 amperes are taken by one rectifier unit. There has been no signal or telephone interference experienced as the result of the operation of this substation. Telephone circuits in the district are carried in underground cables.

Since the converter stations also are relatively new and represent current practise a brief outline of their equipment and operating characteristics may be of some interest. At present there are installed in each of these original substations duplicate compound-wound 360-rev. per min. 60-cycle converters, which were characterized at the time of their installation as being the largest that had been built for 630-volt traction loads. The actual rating of each machine was 3,000 kw. at 630 volts for continuous duty when supplied with six-phase 60-cycle power at 100 per cent power factor; 4,500 kw. at 630 volts for two hours, and 6,000 kw. at 560 volts for three minutes.

The starting and control system for these converters has some unique features; it was designed for star-delta starting by the automatic switching of the high-voltage windings of the transformers; for assuring correct polarity; to avoid error in brush position; and to prevent closing a dead machine onto the bus. The sequence of operations when starting the converter is as follows: To insure correct polarity, the field is excited from the control-battery circuit before the main oil circuit breaker can be closed by the control switch. The closing of the oil circuit breaker completes the closing circuit of the star oil switch, if the brushes on the converter are raised. When the converter has attained synchronous speed a relay bridges a gap in the tripping circuit of the star oil switch, and this circuit is completed by another relay which closes at a definite value of the field current after the field switch has been thrown over to self-excitation. The star oil switch on opening completes the closing circuit of the delta oil switch, provided the oil circuit breaker continues closed. The oil circuit breaker is trip-free during these operations so that full protection is assured. The d-c. switches and circuit breakers are electrically operated, but before the positive switch can be closed the delta oil switch must be closed, brushes lowered, equalizer switch closed, and positive circuit breaker closed.

The oil circuit breaker will open on over-current or low voltage and, by interlock control, automatically opens either the star or delta oil switch and the d-c. circuit breaker. The d-c. breaker opens on over current, reverse current, over speed, or under voltage, and upon opening, opens the positive switch and the equalizer switch.

In the event of a converter flashover, a ground relay opens both the oil circuit breaker and the d-c. breaker; thus it may be seen that many of the operations are automatic, the operator performing only the initial movement of a sequence. The design also assures speed of operation and prevents an operator from making mistakes in putting a converter on the line. At the time of an unexpected failure of the power supply to a substation, the operator was able to clear all feeder circuits and auxiliaries, ordered power on again, started up the station, and established full d-c. feeder service in three minutes.



Section through a converter substation where ventilation and sound-proofing must both be assured

These three substations have been in operation for over two years and all equipment has functioned very satisfactorily. The converters have flashed over occasionally but have not averaged more than two or three per year per machine; and when they do occur, the damage is slight and usually the machine does not have to be left out of service. The flashovers generally occur at times when a heavy load is suddenly cut off, particularly where a limited short circuit occurs which does not open the high-speed breaker but clears itself or is cleared by a subway air circuit breaker. Apparently the flashovers are due to large synchronizing currents caused by angular displacement of the armature after heavy momentary load.

One operator and a helper are on duty in each station at all times.

Electrolysis Survey at Louisville, Ky

Cooperative committee finds that electrical drainage is only a partially effective measure in the protection of pipe systems.

By W. C. White

Southern Bell Tel. & Tel. Co.
Atlanta, Ga.

PREVIOUS to 1926, no concerted action in respect to the electrolysis of underground metallic structures in Louisville had been taken, although the individual action of the water, gas, and electric and railway companies had served to mitigate specific cases of trouble. Realizing that the electrolysis problem could be solved only by securing complete data on all of the underground metallic structures, a conference of the public utility companies was held which resulted in the formation of the Louisville Electrolysis Committee in which all of the public utilities were represented. A citywide electrolysis survey and test procedure were planned the expense of which was prorated among the interested utilities.

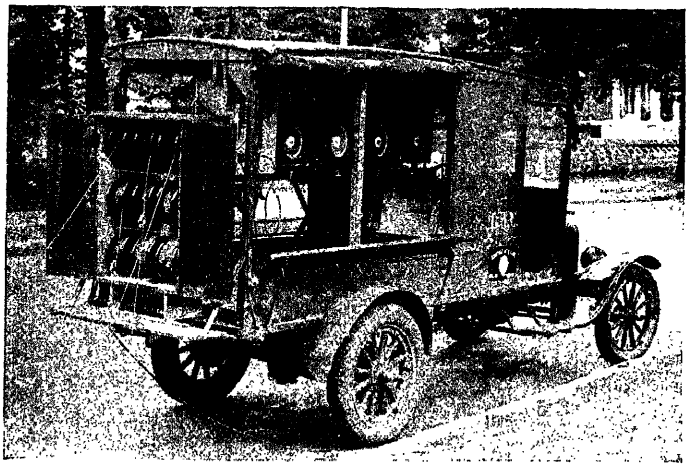
A potential survey was made of the entire city, tests being made at over 600 points. It was found advantageous to use recording meters, and twelve of the smoked chart types were mounted on a truck with suitable switching arrangements for connecting them

---

From "A Cooperative Electrolysis Survey in Louisville, Ky.," presented at A. I. E. E. Southern District meeting, Louisville, Ky., Nov. 19-22, 1930. (No. 30-189.)

between various structures and between structures and earth.

A current survey of sub-surface structures supplemented the potential survey, in determining probable hazardous conditions and furnished valuable data for consideration in the application of remedial measures.



Specially equipped truck typical of those used in Louisville, Ky., electrolysis survey

A current survey of cable systems is a relatively simple procedure and in a great many cases will indicate hazardous conditions where they would not otherwise be located. Approximately 72 such test stations were established on the underground systems of Louisville and 24-hr. records were made of the stray currents. Numerous measurements were also made of track-potential drop and track-potential gradients.

AREAS OF NEGATIVE MAINS
SCALE-VOLTS
NOTE
POSITIVE AREAS SHOWN RED ON SURVEY
NEGATIVE AREAS SHOWN BLUE ON SURVEY

A graphical method of presenting electrolysis survey data for joint study

Soil resistivity tests were made on 180 samples which differed widely, but averaged about 5,000 ohm/cm.

Test data were assembled on cards at the time when current or potential tests were made. A card was prepared giving the number and location of the test point and cross-referenced with the corresponding records. On the reverse side of this card was shown a diagram of the test point and the location of structures to which connections were made. This was done in order that any test could be repeated with identical connections at any time. Those portions of the data capable of graphical presentation were plotted on maps, the areas indicated by the positive potential ordinates being colored red and that of the negative potential ordinates, blue.

When sufficient data were obtained in any section from which definite conclusions could be reached, the electrolysis committee, which met weekly, recommended mitigative measures in order that these might be applied as the survey progressed.

No quantitative results are given, but the success of the methods outlined in improving the general electrolysis conditions in the city has resulted in the continued active existence of the committee which functions as a central clearing house for the investigation of all matters relating to electrolysis in Louisville.

Fog-Type Insulators Eliminate Transmission Line Flashovers

ACCORDING to A. C. Nielsen Company, engineers, Chicago, and J. E. Woods and E. T. Ankele, respectively chief engineer and operating engineer for the Central Power & Light Company, San Antonio, Texas, Lapp standard fog-type insulators have been instrumental in solving a troublesome transmission line problem on the power company's 17-mi., 66-kv. transmission line between Sinton and Robstown, Texas. The line in question is subject alternately to dust and salt fogs, and for some time prior to its reinsulation there occurred an average of some ten insulator failures and consequent service interruption. Analysis of maintenance costs showed an average expenditure of of $152.50 annually to cover necessary replacements, and this together with troubles arising from interruptions to important service brought about a reinsulation which was completed about two and one-half years ago. At that time the 66-kv. pin-type units previously in service were replaced each by three No. 5805 fog-type units. It is stated that insulator failures due to arcover have been eliminated entirely.

The line in question is carried on H-frame structures for the most part, using 22-ft. wooden crossarms giving a 10-ft. 6-in. spacing between conductors. Supporting I-bolts of the insulator strings are grounded to a copper strip running along the top of each crossarm and grounded by wires extending down the pole and wrapped around the base of the pole before erection. The line is rated at 15,000 kv-a., 66 kv.

Railroads *versus* Transmission Lines

Double use of railroad right-of-way permits high-voltages transmission lines to penetrate closely built-up area; also effects economies through coordination in railroad electrification and transmission construction.

By W. W. Woodruff and G. I. Wright

Superintendent Aerial Lines
Philadelphia Electric Company
Associate A. I. E. E.

Engineer Electric Traction
Reading Company, Philadelphia
Member A. I. E. E.

Because of a combination of factors, Philadelphia has been obliged to take several steps in the matter of utilizing railroad rights-of-way for electric power transmission purposes and probably has made advance further along these lines than any other city in this country.

While in other localities, the same factors may not be operative with relative importance it is probable that in the immediate vicinity of any large cities there are, or will be, a combination of circumstances which make the utilization of railroad rights-of-way for electric power transmission purposes both essential and expedient.

It is felt that the results obtained in Philadelphia have been highly satisfactory—beneficial to both the railways and the electrical industry; a wider knowledge as to the general features should be of interest to others.

In order to make the situation clear it will be well to review the various factors involved, briefly tracing developments through several stages.

Philadelphia is located on a peninsula formed by the junctions of the Schuylkill and the Delaware Rivers. South of the Schuylkill River there is an industrial development which extends through Chester and Marcus Hook to the State of Delaware. West of the Delaware River there is an urban section of congested development from one to six miles deep, extending for about twenty miles along the water front. Back of this strip is an area of suburban and semi-rural development forming a belt probably some twenty miles deep and extending from the vicinity of Trenton to the Mason-Dixon Line.

The main steam plants of the Philadelphia Electric Company supplying this region with electrical energy are of necessity located along the Delaware River. A glance at a map of the territory indicates that plants along the Schuylkill would be better strategically for feeding this specific territory. However, large stations on this river are impractical because of the fact that the river flow is comparatively small. The oldest station of the Philadelphia Electric Company is located on the Schuylkill and is still in operation, but for a number of years it has not been advisable to add to its generating capacity and it is doubtful if it will ever be expedient to rebuild it. Consequently, a major problem of means to carry power into Schuylkill station has been to establish other strategic points of large capacity supply, and to tie these in with the larger generating stations in the territory and outside sources of supply.

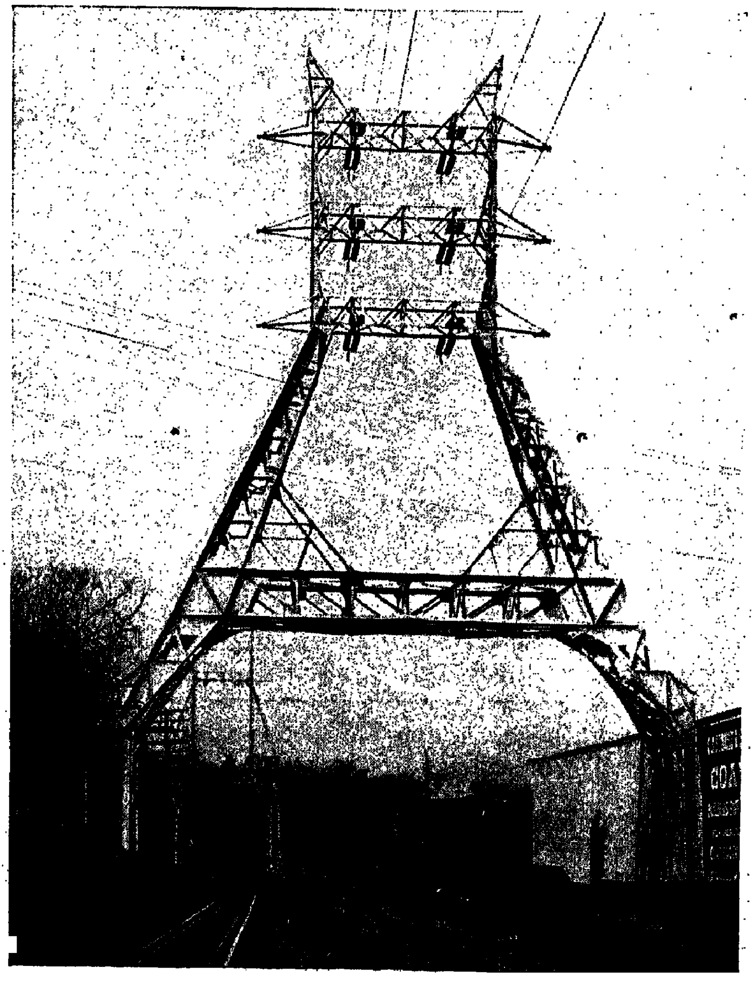

Fig. 1. A 66-kv. four-circuit tower on a restricted right-of-way of the Reading railroad

---

From "Utilization of Railroad Rights-of-way for Electric Power Transmission and Coordination with Railroad Electrification," (No. 30-174) presented at the A. I. E. E. Middle Eastern District meeting, Philadelphia, Oct. 18-15, 1930.

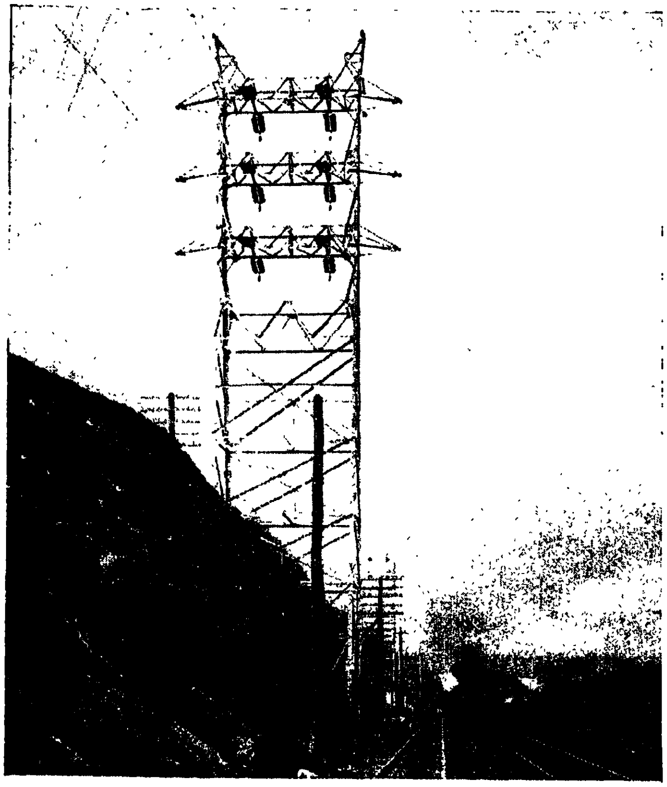

Fig. 2. Four-circuit 66-kv. tower on Reading railroad right-of-way where space is available outside of tracks

In considering the transmission of large blocks of power from outside sources into these urban centers, securing a satisfactory right-of-way to the economic centers of distribution is frequently almost impossible. Through highly developed districts various railroad lines form the only feasible routes. Practically all rights-of-way are railroad property.

The first major problem of this kind in Philadelphia originated about 1915-16, when in order to back up the older station and take advantage of the more economical generation at the newer station it became essential for the electric company to have a 66-kv. transmission line between Schuylkill station in Philadelphia and the new Waterside station in Chester.

The only feasible route between these two stations was along a freight line of the Reading Railroad and a short section of the Pennsylvania Railroad which ran between Philadelphia and Chester. Practically all the property along this railroad route was either already developed or had so much of potential value for future manufacturing sites that its purchase for transmission lines and the securing of a permanent right-of-way over it, were out of the question. Consequently, the transmission line was built largely on the railroad right-of-way. The type of agreement between the companies was one which might naturally be expected in a period when considerable difference of opinion regarding wire crossings, (Pennsylvania General Order No. 13 and other items) existed between the railroads and power companies, and naturally, the agreements had a revocation clause, as was then customary.

A similar situation developed in 1924 in connection with a project of the electric company's for interconnection between Philadelphia and Trenton. The district immediately adjacent to the Richmond Station, from which circuits must run, was so highly developed that the only expedient was to run underground cable for a distance of about four miles and then construct a 66-kv. steel tower transmission line on the Oxford branch of the Pennsylvania Railroad for a distance of about five miles.

The electric company was loath to invest several hundred thousand dollars on a right-of-way where it had no really permanent and irrevocable rights; at the same time, the railroad company was loath to grant any permanent rights on its property owned for transportation purposes. In this case the question was solved by the electric company purchasing in fee simple the additional property outside the line of proposed tracks, which it had been necessary for the railroad company to secure for cutting and filling in road-bed construction. In return the electric company gave to the railroad the right to cross its fee-simple right-of-way to reach adjoining industrial developments wherever necessary, receiving certain rights to maintain wires overhanging the railroad right-of-way.

This agreement was greatly preferable to the revocable type mentioned previously, and was obviously a step forward in cooperation, but could hardly be called complete coordination.

The lines mentioned here were of comparatively small capacity. A much more serious situation developed when it was necessary for the electric company to make plans for bringing into its metropolitan system the Conowingo power output. In this project transmission had to be provided not only for Conowingo power itself but also for power involved in the interconnection between the Philadelphia Electric Company, Public Service Electric and Gas Company of New Jersey, and the Pennsylvania Power & Light Company. Transmission capacity of about 600,000 kw. was required.

Obviously it was necessary to deliver this amount of power well into the highly developed sections of the city at as high a voltage as practicable; and it was equally obvious that it was desirable to bring it in as far as possible on aerial construction. Initially, it was quite evident that a considerable portion of this power must be distributed to the various generating stations in the city by means of 66-kv. underground cable, but on account of the investment, this length of cable must be kept at a minimum.

The only feasible route into the highly developed territory to a point desirable from a distribution

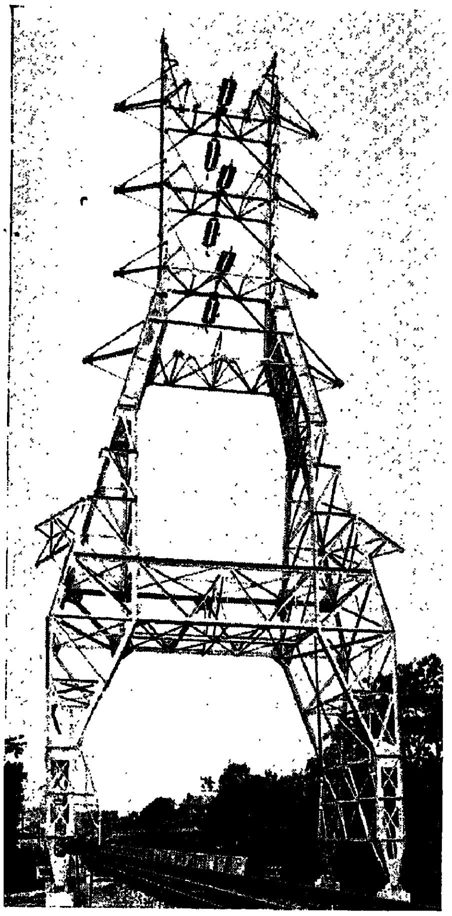

Fig. 3. (Left) Latest type of tower used on restricted Reading right-of-way, providing for three 66-kv. power circuits and four railroad circuits

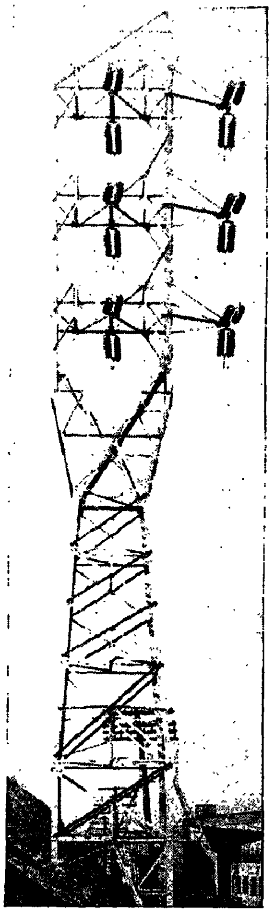

Fig. 4. (Right) Special two-circuit tower for use along side of railroad tracks

standpoint lay along two lines of the Reading Railroad paralleling the Schuylkill River from a point slightly inside the city limits, the latter point being accessible by the conventional aerial construction on private right-of-way.

The situation required an agreement which would be mutually satisfactory to the railroad company and the electric company. Obviously, a project forming so vital a link in so large and important an undertaking must have a permanent status; its continuity must not depend upon any revocable clause or other consideration which did not guarantee permanent and perpetual rights to the electric company. It was equally obvious that the railroad company was in the same situation and must preserve permanent rights for maintaining its operating facilities, as well as the ability to change and increase those facilities as conditions required.

Occupation of railroad right-of-way for electrical transmission can in no wise be considered similar to the utilization of public highways. Due to its prior development the railroad company owns outright and in fee simple the major portion of its right-of-way; consequently, it gives up none of the rights invested in the ownership of property or in any way limits itself in the development of its facilities.

With the Reading Railroad situation, these factors were readily appreciated at the beginning; it was obvious that the conditions required consideration and the finding of a satisfactory solution for—

(a) the designing of the structures of strength adequate to meet severe conditions of climatic loading, and the rules and regulations of any public service body;

(b) designing and locating the structures so that they woudl not interfere with the operation of the railroad company's existing or proposed tracking and facilities;

(c) locating and designing structures to serve as supports without interfering with supports for the future railroad electrification circuits;

(d) in the event of alteration, augmentation, or reconstruction of the railroad facilities, to provide for a joint study of the situation for the most economical means of improvement;

(e) reconstructing or altering the signal and communication system so as to secure satisfactory operation under inductive coordination conditions of future railroad electrification and train control;

(f) the apportionment of costs resulting directly or indirectly from occupation of the railroad company's right-of-way by transmission circuits the electric company's;

(g) the determination of a rental charge for rights of occupation.

The final agreement recognized all these factors. The advantage to the electric company is chiefly a permanent right-of-way through a district precluding independent ownership from either a financial or a public policy point of view. But the electric company assumes a considerable liability.

The benefits to the railroad company are;

(a) the control and coordination of the physical and inductive conflict which might arise were electric lines to be located off the right-of-way but parallel to it;

(b) obtaining supports for its electric transmission and catenary circuits;

(c) the alteration of all signal and telegraph facilities to be unaffected by the operation of the electric company's facilities also safe-guarding railroad electrical operation of trains;

(d) an annual rental charge for occupation of right-of-way.

One important feature should be remembered; were the electric company obliged to purchase a right-of-way, a considerable portion in this case would have either paralleled or been in close proximity to the railroad right-of-way. While the feature of physical interference would have been decreased, the inductive interference situation would have been almost the same as exists with the transmission circuits on the railroad right-of-way.

It is not intended to give here a detailed description of the structural features; they are of greater interest to the structural than the electrical engineer. Only a few points of major interest will be mentioned.

The general electrical features for the electric company's transmission circuits are very much the same as those now used for 66-kv. lines on the conventional steel-tower type construction; that is, the vertical separation between conductors is approximately 10 ft., the minimum clearance to steel work 2½ ft., with the circuits protected by ground wires to avoid lightning disturbances.

In the original installation of about 4½ miles on the main line and Richmond branch of the Reading Railroad, provision was made for four three-phase circuits, it being originally intended that two of these circuits would be reserved for the electric company and the other two positions for the railroad company. (Fig. 1) With the further development of the railroad company's plans it proved feasible to change the formation of the top of the structure so that on the recent Norristown branch construction three three-phase transmission circuits were provided for the electric company and space for two two-wire circuits for the railroad company. (Fig. 3)

To meet the requirements necessitated by future track construction, right-of-way, etc., several expedients in the design of structures were necessary. For the greater part of installation on the main line and Richmond branch, located on a cut on the side of a precipitous slope, there was sufficient room on the side of the cuts and fill to place the structures outside the line of any present or proposed tracks, (Fig. 2); but as the more congested portion of the city was approached, the right-of-way conditions naturally became constricted and in some locations the conditions could be met only by a bridge type of construction which completely spanned a four-track roadway. At other locations it was possible to meet the requirements by dividing the construction, placing the towers on opposite sides of the right-of-way with one circuit going through the center of the structure and the other circuit overhanging the roadway. (Fig. 4)

In the construction on the Norristown branch of the Reading railroad the right-of-way is very much constricted for about the first three miles from termination of the line. Throughout this section it was necessary to utilize the bridge type of construction over a proposed four-track roadway. This roadway involved a project to eliminate a grade crossing and several interesting situations had to be considered.

In certain portions a retaining wall was to be built and the design of foundations for transmission structures must necessarily be coordinated with the design of the retaining wall, the tower footings forming portions of this wall. In another location a steel viaduct was to be constructed so designed at the necessary location that the steel work for the transmission structures could be attached directly.

One circuit of the new construction should now be in operation, service on the initial construction being of something over two and one-half years standing with very satisfactory results.

By words of conclusion, transportation of coal from the mines to urban centers, and of electrical energy from hydroelectric supply sources to these same centers, affect all industry and directly or indirectly a large proportion of the whole country's population.

The more intensive the use of rights-of-way for the transportation of these commodities and the successful coordination of the problems involved, the greater the tribute to the managements of the respective companies. Cooperation cannot but result in substantial public benefits.

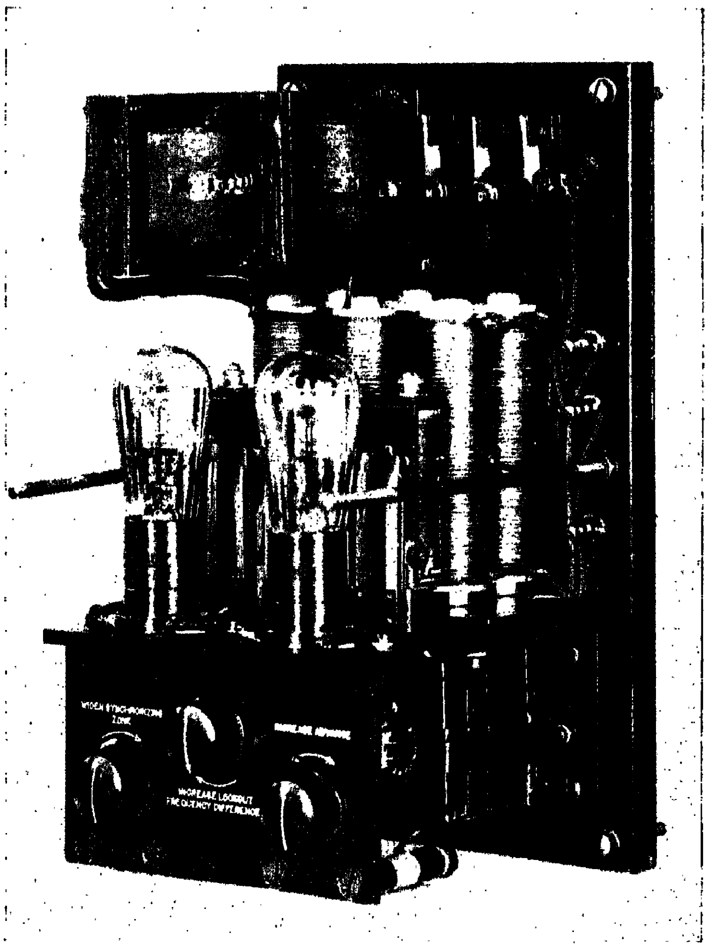
Synchronizing With Vacuum Tubes

THE day's tense moment in the old time power plant came when big machines were synchronized—pilot lights undulating dim and bright, the pointer turning slowly and more slowly; an instant of resolve and the switches slammed in.



No moving parts in this synchronizer

Then either a protecting grunt from the machines, or a sigh of relief from the operator.

All this is gone by, and now even the mechanical synchronizers of recent years may be replaced by a Westinghouse vacuum tube arrangement of 1930 which having no moving parts and demanding but five volt-amperes can draw its energy from a condenser bushing—a substantial advantage over mechanical synchronizers which, requiring 66 to 150 volt-amperes, must be fed from expensive potential transformers. The low power consumption of the new synchronizer is partly due to the use of hipernick in small transformers embodied in it.

The principle of operation involves current based on the beat frequency between the two circuits rectified and used to control the grids of the vacuum tubes. The two simple adjustments are made by radio type rheostats. One changes the frequency difference at which it will synchronize (usually $^1/_6$ cycle); the other adjusts the angle of advance to allow the circuit breaker to close at exact synchronism.

The new synchronizer is twice as accurate as the most skilful human operator, and should last longer if calculation goes for anything; its only mortal elements being two standard radio tubes good for 1000 continuous hours and used but five minutes a day.

Saturation Phenomena in Potential Transformers

Experiences with grounded-neutral Y-connected potential transformers on ungrounded systems emphasize certain dangerous "saturation phenomena" which frequently occur. Two applications are outlined here and preventive measures recommended.

By C. T. Weller

General Engineering Laboratory,
General Electric Company
Member A. I. E. E.

METHODS for preventing the occurrence of the peculiar and dangerous "saturation phenomena" caused by the two applications of Y-connected potential transformers to three-phase, three-wire systems are outlined in this paper. One of the systems operates at 12 kv., 60 cycles, and the other operates at at 110 kv., 25 cycles. In each case the neutral of the potential transformer bank was grounded but the section of the system involved was ungrounded. Although not in accordance with the best practise for power transformers, (because of the apparent suppression of the third harmonic and its multiples of exciting currents), such applications have been made for the affording of protection of equipment against grounds, the economy resulting from the use of L/N instead of L/L (abbreviations L/N for "line-to-neutral" and L/L for "line-to-line" are used) potential transformers and the maintenance of the isolated-phase scheme for such installations.

It may not be generally appreciated that such applications frequently endanger connected equipment in addition to creating special relaying and synchronizing problems. Sufficient data are included to illustrate the inherent danger and to afford a basis for the "general recommendations" made. (For discussions from theoretical standpoints, companion papers, "Physical Nature of Neutral Instability," by A. Boyajian and O. P. McCarty, and "Theory of Abnormal Line-to-Neutral Transformer Voltages," by C. W. La Pierre, are relied upon. These papers were presented at the Southern District meeting in Louisville, Ky., Nov. 19-22, 1930, and are reviewed elsewhere in this issue.)

The potential transformers were designed for normal operation at L/N voltage and for emergency (two-hour) operation at L/L voltage. Temporary operation in case of a ground on one line of the ungrounded section, which would apply L/L voltage to two of the potential transformers, was thus provided. Their ratings are given in Table I.

TABLE I
RATING OF POTENTIAL TRANSFORMERS

		Volts	
Cycles	Volt-amperes	Operating (L/N)	Circuit (L/L)
60	200	7,200:120	12,000
25	1,000	63,500:63.5	110,000

SUMMARY OF RESULTS

The peculiar and dangerous saturation phenomena here described briefly were obtained frequently when voltage was applied to grounded-neutral, Y-connected potential transformers on temporarily ungrounded systems by closing an oil switch; at other times, the anticipated normal results consisting of balanced L/N voltages equal to approximately 58 per cent of the applied L/L voltages were obtained under the same

---

From "Experiences with Grounded-Neutral Y-Connected Potential Transformers on Ungrounded Systems," (No. 30-182) presented at the A. I. E. E. Southern District meeting, Louisville, Ky., Nov. 19-22, 1930.

system conditions. The operating conditions are indicated in Fig. 1a when "oil switch *I*" is open and voltage is applied to "ungrounded section *U*" from "source *II*" by closing "oil switch *II*." Also, test connections are given in Fig. 3. The phenomena will be considered under three classifications, *A*, *B* and *C*; (a fourth classification *D* covers a somewhat special case). The phenomena are represented in Fig. 2 and are shown in Figs. 4, 5, 6, and 7. Representative secondary voltmeter readings obtained are given in Tables II and III.

Phenomenon *A* consists of a displacement of the neutral (or ground) of the potential transformers from its normal position at the center of gravity of the delta-voltage triangle to a position near any vertex; the displaced neutral may be either inside, on the edge, or outside of the triangle. Approximate *L/L* voltage then appears on two of the potential transformers, while a small voltage of very distorted wave shape appears on the third potential transformer. Phenomenon *A* occurred frequently under some conditions (but not at all under other conditions) on both the 12- and 110-kv. systems.

‡Phenomenon *A* not obtainabl .

Phenomenon *B* consists of an oscillation at double frequency of the neutral (or ground) of the potential transformers outside of the delta-voltage triangle. Equal or balanced voltages of unsymmetrical wave shape and about 2.7 times normal magnitude appear on the three potential transformers. These voltages are accompanied by balanced exciting currents of sharply peaked wave shape and about 10 times rated full-load current in magnitude; operation well up on the saturation curve is indicated thereby. Distinctly audible beats occur with a frequency of from about 30 to 170 per minute; excessive corona also occurs. Phenomenon *B* is represented in Fig. 2c.

Phenomenon *B* started frequently under some conditions but held only long enough to take instrument readings at rated *L/L* voltage or higher on the 12-kv. system; and even then, only at certain times.

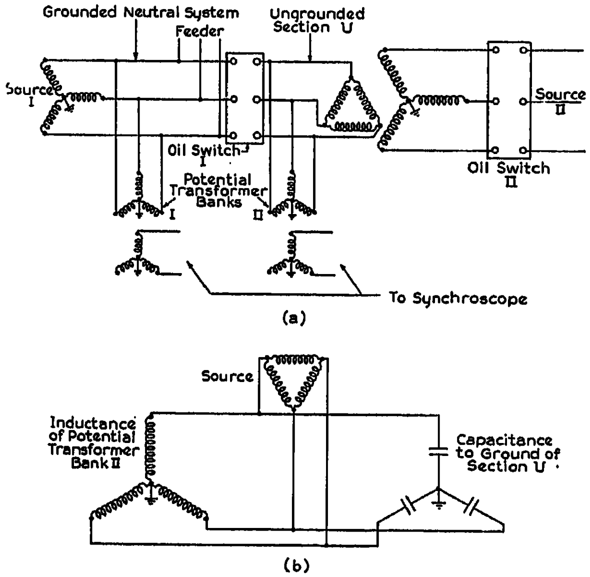

Fig. 1. Schematic Diagrams: (a) typical system connections, (b) elements of circuit U

Phenomenon *C* consists of an oscillation at half the frequency of neutral (or ground) of the potential transformers inside of the delta-voltage triangle. Equal or balanced voltages of unsymmetrical wave shape and about 1.2 times normal magnitude appear on the three potential transformers. These voltages are accompanied by balanced exciting currents of sharply peaked wave shape and about 15 times rated full-load current in magnitude; operation at a point on the saturation curve well beyond that for phenomenon *B* is indicated thereby. Distinctly audible beats occur with a frequency of about 240 per minute. Phenomenon *C* occurred frequently under one condition only on the 12-kv. system.

The occurrence of phenomena *A*, *B*, and *C*, as shown by sustained instrument readings, was prevented in all cases by adding sufficient secondary burdens of resistance. The values (at 120 volts) of the protective resistor burdens required on the 12-kv. system are as follows: phenomenon *A*, at all voltages tried, 72-volt-amperes; phenomenon *B*, about 20 volt-amperes; phenomenon *C* at rated *L/L* voltage, 72 volt-amperes. A burden of 72 volt-amperes, therefore, was provided for each transformer. Similarly, the burden values (at 63.5 volts) required on the 110-kv. system are: phenomenon *A* (and *B*) at all voltages tried, 900 volt-amperes per transformer with one bank of potential transformers or 600 volt-amperes per transformer with two banks of potential transformers.

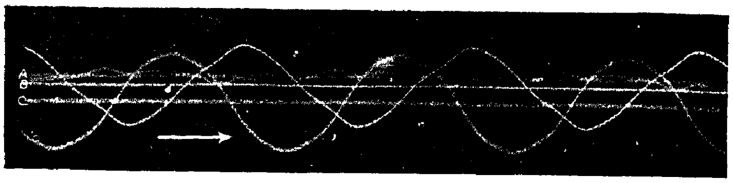

Fig. 4. 7.2-Kv. potential transformers—phenomenon A

Curve *A*, voltage 2-*N*; curve *B*, voltage 3-*N*; curve *C*, voltage *N*-1

In further tests made on the 12-kv. system (capacitance to ground 0.035 μf.), phenomena *A* and *B* also occurred when a bank of 13.2-kv. potential transformers was connected in multiple with the bank of 7.2-kv. transformers; however, neither *A* nor *B* occurred when the 7.2-kv. bank was disconnected.

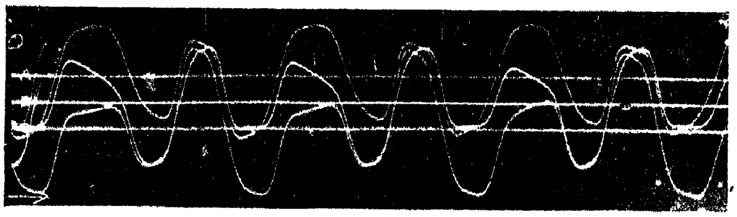

Fig. 5a. 7.2-Kv. potential transformers phenomenon B

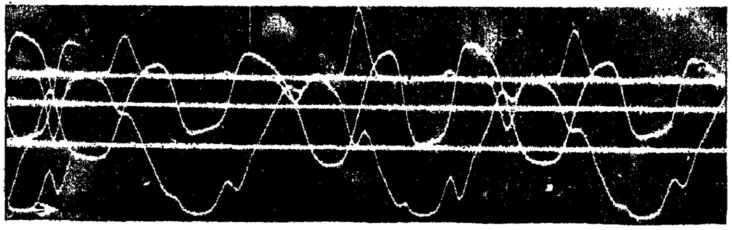

Fig. 5b. 7.2-Kv. potential transformers—phenomenon B

Curve *A*, current line 2'; curve *B*, voltage 2-*N*; curve *C*, voltage 3-2

Phenomenon *B* occurred when a bank of 6.9 kv., 1.5-kv-a. distribution transformers was connected in alone. A different phenomenon (*D*) occurred when the 5.96-kv. tap on this bank was used (this tap of course would not be used in practise on a 7.2-kv. circuit). Phenomenon *D* consisted of an oscillation at triple frequency of the neutral (or ground) outside of the delta-voltage triangle; equal or balanced voltages of about 3.5 times normal appear on the three transformers; audible "buzzing" and excessive corona occur. Phenomenon *D* did not hold long enough at any time to obtain a complete set of instrument readings; evidently D is easier to prevent than B.

SIGNIFICANCE OF RESULTS

Phenomena A, B, and C and the conditions under which they occur are not characteristic of any particular ungrounded system or type of transformer. As phenomena B and C endanger the potential transformers themselves so the former also endangers other connected equipment. All three phenomena tend to cause incorrect synchronizing and incorrect relay operation; the difficulties depend to some extent on the secondary connections used.

Fig. 6.   7.2-Kv. potential transformers— phenomenon C

Curve A, voltage 3-N; curve B, current line 3′; curve C, voltage 1-3

Y-Connected Secondaries. Ordinarily, if any one of the L/N voltages should be chosen for synchronizing purposes, it is evident that the indications frequently obtained would be considerably in error both in magnitude and in phase position, to say nothing of wave shape and frequency. This particular difficulty could be overcome readily by using any one of the L/L voltages; however, the correct effective secondary values would not be indicated by the voltmeters for phenomena B or C, although this error would be small (see Table II); also, there might be some disturbance caused by throwing together two systems, one of which was being subjected to phenomena A, B or C.

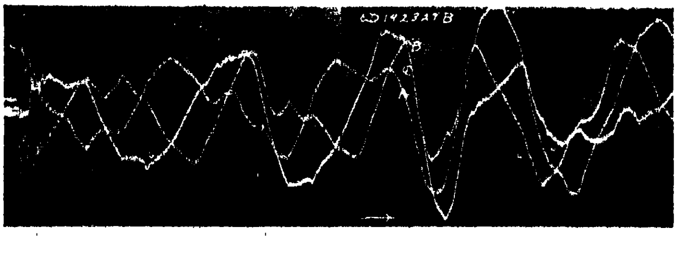

Fig. 7.   Six 63.5-Kv. potential transformers (two Y-banks)—start of phenomenon A (and B)

Curve A, voltage 3-N; curve B, voltage 2-N; curve C, voltage 1-N

"Broken-Delta"-Connected Secondaries. Ordinarily, the high-impedance "ground relay" connected across the "broken-delta" would operate frequently, although no accidental ground existed on the system.

These difficulties can be overcome in various ways; such as by grounding the sections of the system, by using the L/L connection for all potential transformers, by providing protective resistor burdens for L/N-rated potential transformers or by using potential transformers of considerably higher than L/N-voltage ratings for the L/N connection, and thereby lowering the point on the saturation curve at which the transformers normally operate.

GENERAL RECOMMENDATIONS

These recommendations are intended to serve as a guide in the application of grounded-neutral, Y-connected potential transformers to three-phase, three-wire systems or sections thereof, which temporarily or permanently are ungrounded.

TABLE IV
APPROXIMATE RELATIVE VALUES OF PROTECTIVE RESISTOR BURDENS REQUIRED TO PREVENT OCCURRENCE OF PHENOMENA A, B, AND C

	Y-Connected Potential Transformers		
System or Section Neutral	Primary Neutral	Normal Voltage Rating	Relative Value of Burdens
Ungrounded temporarily	Grounded	L/N	1.0
	Grounded	L/L	0.5
	Grounded	$2 \times L/N$	
Ungrounded permanently	Grounded	L/N	1.5
	Grounded	L/L	0.75
	Grounded	$2 \times L/N$	0.25

Protective resistor burdens should be used in practically all cases if the occurrence of phenomena A, B, and C is to be prevented under all possible operating conditions. It is always desirable to keep the volt-ampere ratings of such burdens as small as possible and this involves a consideration of the characteristics of each proposed installation. The magnitude of the burdens provided for the potential transformers of L/N-voltage design on the 12-kv. and 110-kv. systems was determined experimentally and a rough idea of the general requirements was thereby obtained; the magnitude of these burdens constitutes the standard of reference for the relative values in Table IV.

A differentiation is made in Table IV between temporarily and permanently ungrounded systems. The ratio of the volt-ampere ratings of the protective burdens recommended for the two conditions is about 1 to 1.5. It is believed that a greater margin of safety is desirable for permanently ungrounded systems, since they are always subject to disturbances tending to displace the neutral from its normal position; installations of potential transformers on such systems have not been investigated.

Physical Nature of Neutral Instability

Experience has established the fact that three-phase-system neutrals may become subject to strange phenomena of instability under apparently normal conditions. The authors give facts and explanations based upon extensive experimentation.

FROM time to time the attention of the Institute has been drawn to some peculiar troubles accompanying the operation of power or potential transformers connected Y-Y with grounded neutral on an otherwise isolated system. (See bibliography) The phenomena under discussion are found only in circuits with capacitance and saturation, and therefore it is proposed to build up the present discussion starting with an analysis of the characteristics of iron-core reactors in combination with capacitors.

Iron-Core Reactor Shunted by a Capacitor. When the volt-ampere characteristics of a saturating inductance (such as the magnetizing current of a transformer) and of the shunt capacitance are plotted, the resultant characteristic curve of the combination is as shown by the curve of Fig. 1. It is realized that the exciting current of a transformer is much more complicated than that of a capacitor. While the latter may be considered as yielding a pure leading current, the former always will contain a lagging component, a power component, and harmonics. Since the lagging component frequently is 80 or 90 per cent of the total exciting current, its behavior in the network is of importance.

Negative or Leading Reactance Zone O-A (Fig. 1). In this zone I_o is leading and the combination behaves like a negative, or capacitative, reactance. As the graph is substantially straight the circuit parameter (the equivalent reactance of the combination) is constant, and like any linear impedance the behavior of the outfit in a network in combination with other impedances is stable.

Unstable Zone A-B (Fig. 1). In this zone the resultant current I_o still is leading, but instead of increasing with increasing voltage it diminishes. Consequently while the gross apparent reactance still is negative, leading, or capacitative, the differential or incremental reactance (the reactance for increases or reductions in current) is positive, lagging, or inductive. Thus,

$$X \text{ considered as } \frac{E}{I} \text{ is negative, leading, capacitative,}$$

and

$$X \text{ considered as } \frac{\Delta E}{\Delta I} \text{ is positive, lagging, inductive.}$$

Such a characteristic *under suitable network conditions* may become a source of instability somewhat analogous to the case of an arc.

Positive or Lagging Reactance Zone B-D (Fig. 1) In this zone the current is lagging and increases with the voltage (even though not in exactly direct ratio). Thus both the gross and the incremental reactance of the combination are lagging or inductive, therefore the behavior of the combination is approximately that of a plain saturating inductive reactance. An equilibrium point in this zone tends to be stable.

Fig. 2. (Right) Inversion in a single-phase circuit

(A) Single-phase circuit with unstable neutral
(B) Vector diagram for normal neutral condition
(C) Vector diagram for inverted neutral
(D) Same as (C) with prominent quadrature component

A Multiple-Valued Function. Aside from the change in the value and algebraic sign of the resultant reactance from zone to zone of the characteristic curve, another interesting feature to observe is the double-valued character of the curve. Over a wide range, including *O-A*, *A-B* and part of *B-D*, and the corresponding zones below the horizontal axis, there are to any given value of current, two totally different possible values of voltage.

Resonance and Natural Frequency. At point *B* (Fig. 1), where the resultant current I_o is zero, there is parallel resonance at impressed frequency, that is, the outfit has a natural frequency of oscillation equal to that of the impressed voltage. In such circuits currents undoubtedly are distorted, but that does not invalidate conceptions of resonance and free oscillations.

Classification of Abnormal Phenomena. In analyzing the various abnormal phenomena it is found that

---

From "Physical Nature of Neutral Stability," (No. 31-186) presented at the A. I. E. E. Southern District meeting, Louisville, Ky., Nov. 19-22, 1930.

they fall into two distinctive groups—(1) those which involve merely a shifting or inversion of the neutral and are primarily phenomena of fundamental impressed frequency; and (2) those which do not disturb the fundamental frequency voltages, but introduces an oscillation into the neutral, higher or lower than the impressed frequency.

I—Inversion of Neutral

Inversion in a Single-phase Circuit. Referring to Fig. 2A, let branches 1 and 2 be duplicates; a point of equilibrium for N obviously is half-way between the potentials of the terminals, as shown in Fig. 1 and also by the vector diagram of Fig. 2B: where

$$E_1 = E_2 = E_0/2,$$

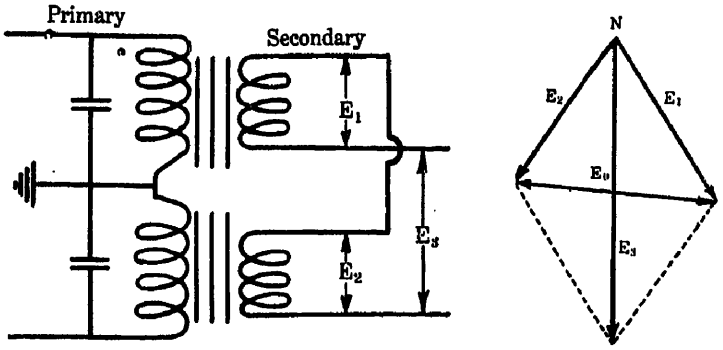

Fig. 3. (Left) Circuit for single-phase neutral instability tests, and (Right) vector diagram showing neutral shift

where E_0 is the line voltage, and E_1 and E_2 are the branch voltages. If the branch voltages E_1 and E_2 are within the zone O-A (as shown in Fig. 1), the potential of N once so established (Fig. 2B) will be normal and stable. The line current will be leading, both branches acting capacitatively. Assume, however, that when the line switch is closed, the starting transient unbalances the voltages and carries one of the branch voltages, say E_1, into zone A-D; a new and abnormal condition of equilibrium may now become established as follows:

Considering the characteristic curve (Fig. 1), it is seen that not only

$$E_1 + E_2 = E_0,$$

but also,

$$E_1' + E_2' = E_0.$$

In the latter case, E_2' is negative, E_1' is greater than the line voltage (see also the vector diagram of Fig. 2C), and the neutral potential is outside of the line voltage. Obviously, one leg or branch of the circuit is acting inductively; the other, capacitatively.

With a different line voltage say E_0'' (Fig. 1)—a still different type of abnormal equilibrium may take place with the leg or branch voltages assuming the values E_1 and E_2 respectively, in which case then, both branches are operating capacitatively, one overexcited, the other underexcited. A still different position of the neutral may correspond to one leg operating in the zone A-B, the other in the zone B-D, both legs overexcited. Such a case was observed in single-phase tests.

Inversion in a Three-Phase Circuit. If the neutral of a Y-Y or Y-broken-delta bank of transformers is grounded on a circuit which otherwise is isolated, the neutral of the transformers is joined to the neutral of the line capacitance to ground, resulting in an equivalent circuit such as shown in Fig. 5. Each leg of this network will have a volt-ampere characteristic similar to Fig. 1, capable of acting either as a capacitative reactance or as an inductive reactance.

Assuming the three legs to be duplicates, the normal position of the neutral will be at the center of gravity of the line voltage triangle. However, other positions of equilibrium also exist, for instance, two of the legs operating in the zone B-D with a lagging power factor, and the third in the zone O-A with a leading power factor, as explained for the single-phase circuit, in which case one leg will be reversed and the other two will be greatly overexcited; the neutral will fall outside of the triangle of line voltages. The alternative case, in which all the legs operate capacitatively, one in the zone O-A, the other two in the zone A-B, as discussed in connection with single-phase neutral shift (the neutral falling just inside the line voltages) also has been observed. (See companion paper by C. T. Weller.)

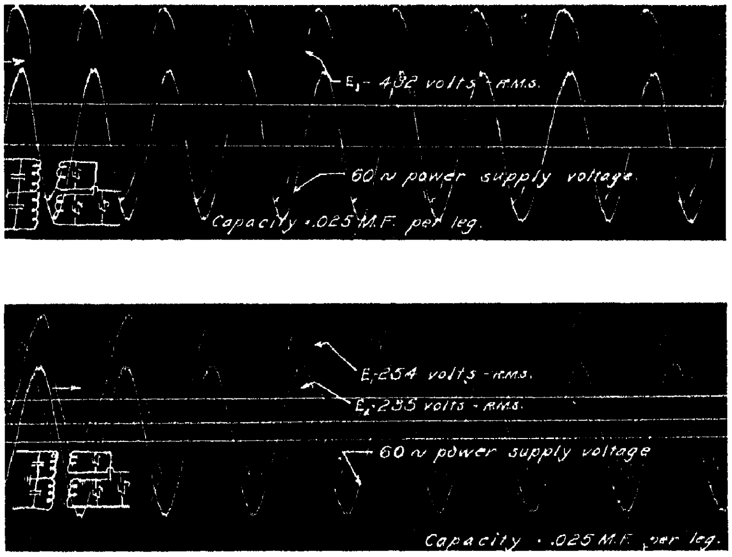

Fig. 4. Oscillograms showing neutral shift in circuit of Fig. 3

Since any one of the legs may become underexcited, depending upon the instant of switching, there will be at least three abnormal stable positions of the neutral.

Single-Phase Inversion Tests

Two duplicate standard potential transformers, rated 13,200/100 volts, were connected in series to yield a neutral point as shown in Fig. 3, and each transformer was shunted by a variable capacitance the settings of which were made alike in all cases. When the circuit voltage was brought up gradually the neutral was found to be normal in all cases. However, when the voltage to the circuit was applied suddenly, inversion of the neutral point was observed over a fairly wide range of capacitances, this range depending on the excitation of the transformers. The secondaries (low-voltage) of the potential transformers may be seen connected in series-opposition to segregate the abnormal voltage component of the neutral. Obviously, with balanced branch voltages the terminal voltage of the secondaries as connected would be zero, but if the neutral should shift, invert, or oscillate, the phenomenon will appear in the resultant voltage of the two secondaries in its pure form, unmixed with normal voltage.

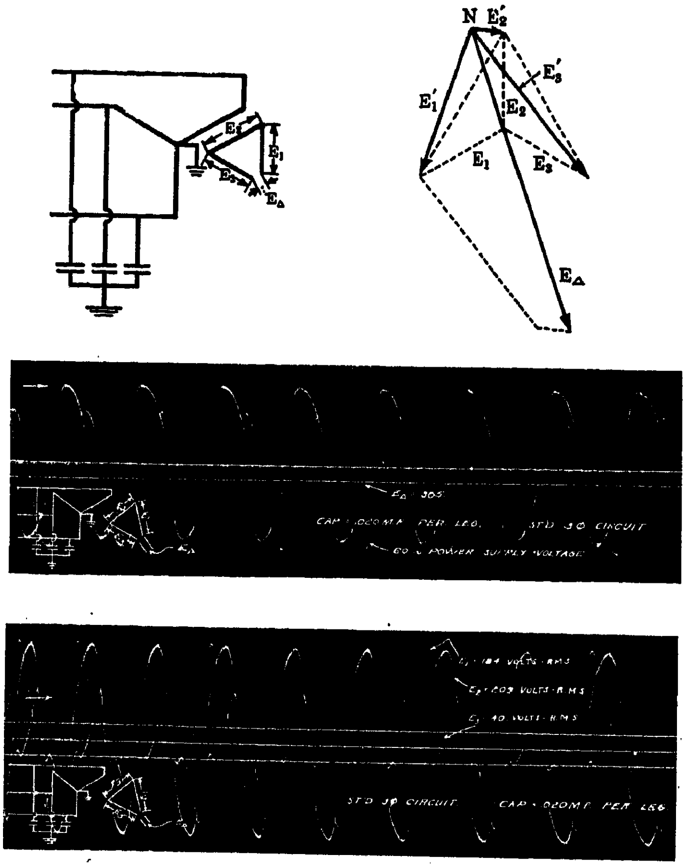

Fig. 5. Circuit and test results for three-phase-neutral instability

With line voltages representing from 100 to 120 per cent excitation on the potential transformers the neutral of this single-phase bank frequently would come in inverted, with capacitances of from 0.025 to 0.050 mfd. across each unit (on the high voltage side). With line voltage representing 120 per cent excitation, a typical set of readings gave $E_1 = 193\%$, $E_2 = 178\%$, and $E_3 = 328\%$ of the values corresponding to normal neutral.

The oscillogram of Fig. 4 shows that all voltages are of fundamental frequency and reasonably good wave shape. The vector diagram of Fig. 3 shows the branch voltages to be of the same order of magnitude, and the neutral to have shifted almost in quadrature with the impressed voltage. The significance of this is that one of the branches is operating capacitatively in the zone *A-B* (Fig. 1) fairly close to *B*, the other inductively in the zone *B-D*, but again fairly close to *B*. Only such a combination will give an inversion in which E_1 and E_2 will be so nearly equal.

Three-Phase Inversion Tests

The circuit is shown in Fig. 5; it should be observed that when the neutral is normal the voltage across the corner of the delta will be zero; but when the neutral moves from this position it will show in the corner of the delta. Thus, only those phenomena which disturb the neutral can appear across the corner of the delta; all others cancel out. Voltage oscillograms taken at this point therefore show clearly the nature of the disturbance of the neutral. The magnitude of this voltage will be three times the corresponding component in each leg. The vector diagram of a typical case of inversion is shown in Fig. 5.

The oscillograms of Fig. 5 give evidence that the phenomena are of fundamental frequency and of reasonably good wave shape. The data show that two legs are overexcited (acting inductively) and one underexcited (acting capacitatively). The fact that the neutral shift is not exactly parallel to the normal leg voltage of the underexcited leg is due largely to the losses.

It was observed that upon switching in, any one of the three legs might come in reversed.

II. Oscillating Neutral

Oscillations at half, double, and triple frequencies, with low-frequency beats and high-frequency harmonics also have been observed.

In Fig. 7 is illustrated a single-phase case in which the oscillation persisted indefinitely. Note the purity of the wave shape and that it is exactly one-half of the impressed frequency. In examining the waves of the leg voltages (E_1 and E_2) nothing else of importance is found other than a fundamental and a half-frequency harmonic.

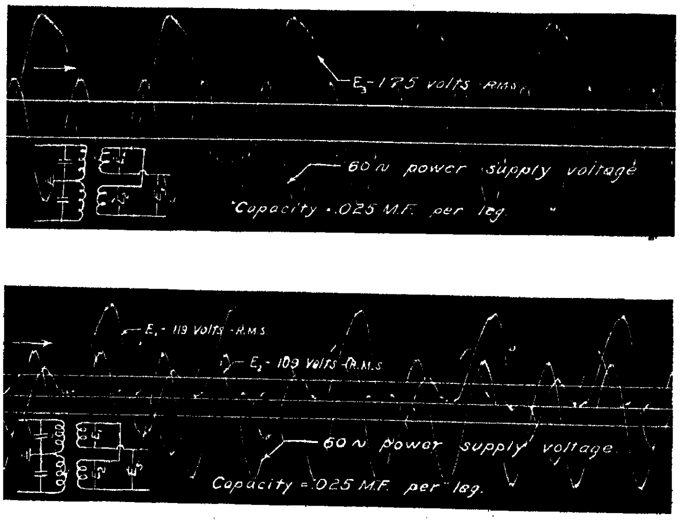

Fig. 6. Oscillograms of oscillating single-phase neutral

In Fig. 8 is given the timing wave (supply voltage), leg voltage and the neutral voltage for a typical case of oscillation in a three-phase circuit. The neutral voltage is observed across the corner of the delta. The characters of these waves may be seen to be substantially the same as in the single-phase tests.

The explanation of the persistance of such oscillations is as follows:

It is commonly known that a Y-open-delta transformer can be used to derive triple-frequency single-phase power from a fundamental-frequency three-phase source. For instance, at nominal 60-cycle densities around 170 kilolines per sq. in., third-harmonic outputs as high as 100 kw. per 1,000 lb. of core can be obtained. This flow of power must be reversible, that is, if the harmonic current is reversed, power must flow from the harmonic to the fundamental.

The free oscillation naturally will be distorted and have higher harmonics. If the impressed frequency is identical with one of these harmonics, power can flow from it to the oscillation as from a higher harmonic to its fundamental, to take care of its watt losses.

A harmonic can deliver to the oscillation not only a certain amount of watts, but also a certain amount of reactive volt-amperes. This is most significant because it makes persistence of oscillations possible without exact resonance. For instance, if the supply frequency is 60 cycles and the natural frequency of oscillation of the circuit is 21 cycles the circuit may oscillate at one-third frequency or 20 cycles just as readily. The difference between oscillating a little off-resonance (20 cycles) and at exactly free resonance (21 cycles) is that the latter requires watts for its maintenance, while the former requires both watts and reactive volt-amperes.

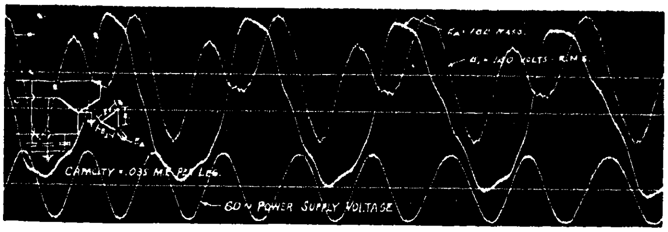

Fig. 7. Oscillogram of oscillating three-phase neutral

Thus, within the extent of the ability of the oscillation to draw watts through one of its harmonics, a free oscillation can be maintained with higher and higher losses; while, within the ability of the oscillation to draw reactive volt-amperes through one of its harmonics, a free oscillation can be maintained farther and farther off from the true natural frequency of the circuit.

CONCLUSIONS

1. Operation of potential transformers in Y-Y with neutral grounded on an otherwise isolated system, (whether permanently or occasionally isolated system, or section of a system), is a somewhat questionable practise unless protective measures are used.
2. Aside from possible trouble due to third-harmonic-voltage intensification, which is so well-known, it is found that with favorable capacitance values from line to ground, natural oscillations are possible around one-half normal frequency as well as double normal frequency.
3. Aside from oscillations, there is the possibility of the inversion of the neutral being unsafe for equipment.
4. Explanation of the neutral shift or inversion is based upon the fact that the combination of a saturable inductance and a constant capacitance has a multi-valued characteristic curve, with leading and lagging zones. For instance, if one leg operates in a leading zone and the other two in a lagging zone, the potential of the neutral is thrown outside of the triangle of line voltages.
5. Persistence of oscillations is accounted for as follows: The frequency of the free oscillation of the circuit must approximate harmonic relationship to the impressed frequency. When the oscillation is at a frequency higher than the impressed, the active and reactive energy flow to it is similar to that from fundamental to higher harmonics, as in static frequency multipliers. When the oscillation frequency is lower, such as one-half of the impressed frequency, the impressed frequency stands in the relationship of a higher harmonic of the oscillatory frequency and the energy flow is reversed because the location of power and load are interchanged.
6. In potential transformer banks intended exclusively for relaying purposes the secondary (or a tertiary) could be connected in delta, and closed through a resistance just high enough to protect the bank from burnout in times of line-to-neutral short circuits; then troubles due either to inversion or oscillation would be entirely eliminated. However, if the bank is to be used for metering as well as for relaying, th currents circulating in the delta due to unbalanced line-to-neutral conditions in the system may affect adversely the metering accuracy of the outfit.
7. Loading the potential transformer from line to neutral also tends to stabilize the neutral and prevent inversion and oscillations. However, this will be a constant load at impressed frequency. It is believed that such a load should be *at least* of the same order of magnitude as the magnetizing volt-amperes of the transformers at normal operating voltage.
8. Operation of potential transformers approximately at half rated voltage is found to reduce greatly the chances of self-excited oscillations. The damping load of the order of the magnetizing volt-amperes at such low excitations is small and well worth-while. Low-density operation and protective load are desirable also from the standpoint of third-harmonic phenomena.

Progress in Fuel Utilization

IN discussing progress in development and application of boilers and furnaces a recent report of the Fuels Division, The American Society of Mechanical Engineers, says in part:

"The trend toward higher steam pressures and temperatures continues not only in public utility plants but also in industrial plants. Boiler manufacturers are in position to erect commercial units supplying steam up to 1800 lb. per sq. in. and 850 deg. fahr. total temperature. A boiler of the series type suitable for delivering steam at 3,500 lb. pressure is being completed by the Babcock & Wilcox Company and is to be given to Purdue University for experimental work. An experimental and special form of superheater installed at the Detroit Edison Company has operated successfully for some time, delivering steam at practically 1,200 deg. fahr.

"The many novel ideas in boiler-furnace design which have been incorporated in the past few years have received exhaustive tests in commercial operation and the wealth of combustion data thus accumulated has served to eliminate unnecessary refinements. Early enthusiasm over the performance of furnace water walls has been somewhat tempered, and an economical limit for their use has been found in moderate- and small-sized boilers operating under certain restricted conditions.

"Considerable improvement in combustion conditions with stoker-fired boilers has been attained by means of judiciously proportioned water-cooled protecting walls and arches. Simultaneously the air-cooled and sectionally supported refractory walls have amply justified expectations in many cases. Notable progress has been made in the rate of firing per boiler unit. The record-breaking performance of the new boilers at the East River station of the New York Edison Company is due mostly to the excellent functioning of the fin-tube furnace of 39,000-cu. ft. volume, where up to 75 tons of powdered coal have been burned per hour."

Theory of Abnormal Voltages

Abnormal line-to-neutral transformer voltages may be said to be self-excited by successive alternate saturations and limited in magnitude and frequency by multiple saturations. Outline of theory is given here.

By C. W. LaPierre

General Engineering Laboratory,
General Electric Company,
Schenectady
Associate A. I. E. E.

ABNORMAL voltages considered in this paper arise incident to the occurrence of a large harmonic of fractional, even, or odd frequency in the line-to-neutral voltages of certain Y-connected transformer circuits. These phenomena have been described before (see Bibliography) and additional data concerning them are available in the two companion papers reviewed elsewhere in this issue,—one by C. T. Weller and one by A. Boyajian and O. P. McCarty.

ABNORMAL VOLTAGES

The circuit in which the phenomena occur is represented by Fig. 1A or Fig. 1B. The abnormal harmonic is a zero-phase-sequence component existing in the transformer or line-to-neutral voltages. The frequency of this harmonic and, to a lesser extent, its magnitude, are of special interest. In the transient state occurring soon after the circuit is connected to the source the harmonic voltage may be so highly irregular as not to possess a definite frequency. However, after the voltages continue for a while they either disappear altogether or settle down to a fairly constant frequency and magnitude. In these sustained conditions the frequency of the predominant harmonic has been observed to be either one-half of, equal to, double, or triple, the supply-voltage frequency; the problem is clarified, however, if it is realized at once that these frequencies are only special cases of the irregular transients. For the latter, all frequencies are possible (within wide limits), whereas in the former only four are found to occur.

In this abstract the fundamental origin of all of the abnormal voltages is explained. The conditions surrounding the occurrence of sustained voltages are discussed in detail in the complete paper.

The fundamental explanation of the abnormal voltages just described is quite simple; the explanation is handicapped, however, by the complexity of the representative circuits of Fig. 1. An analysis of these circuits must involve the three line-to-neutral or transformer voltages, and the three transformer and three capacitor currents. Add to this a 5,000:1 variation in the open-circuit inductance of each transformer and the problem becomes even more formidable. Obviously the procedure must be simplified. In this paper the simplification has been accomplished by the adoption of an equivalent circuit.

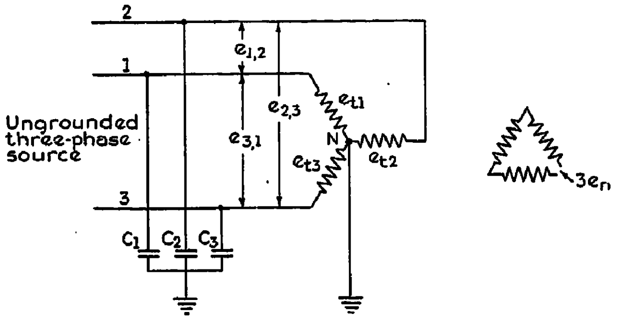

Fig. 1A. Representative circuit

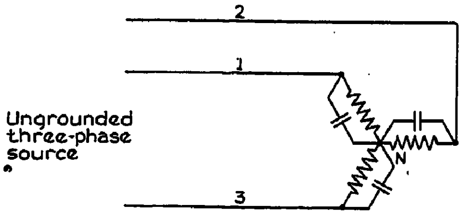

Fig. 1B. Simplified representative circuit

Although Fig. 1A represents the circuits in which the phenomena have been observed to occur, the equivalent circuit of Fig. 2A may be expected to produce the same tranformer voltages and is identical in that respect to Fig. 1A under certain conditions. In Fig. 2A the capacitor voltage is equivalent to the neutral or harmonic voltage and may be visualized directly without the necessity of separating it from the transformer

---

voltage as is the case in Fig. 1A. It is the variation in the voltage across this capacitor which introduces the harmonics in the transformer voltages; furthermore, in Fig. 2A the capacitor or neutral voltage is the only voltage that must be determined. The three transformer voltages may be obtained by simply adding the capacitor or neutral voltage to each of the known supply voltages.

Fig. 2A. Equivalent circuit

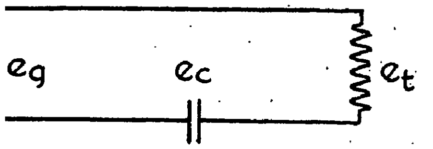

Fig. 2B. Single-phase circuit

Thus by adopting a particular type of supply it is possible to reduce the problem to a consideration of the voltage across a single capacitor. While it is theoretically immaterial which figure is used in the following discussion, the processes to be described will have far greater practical significance if they are based upon Fig. 2A.

ORIGIN OF ABNORMAL VOLTAGES

Saturation during the first cycle after connecting a transformer to a source of voltage is of common occurrence. Such saturations are the result of initial conditions of voltage and residual core densities. In transformers connected directly across a single-phase supply, the initial saturation results in the familiar starting currents represented by Fig. 3. This curve actually consists of a succession of saturations, all in the same direction. Magnitude of the peaks gradually diminishes until normal densities are not exceeded. Each saturation is an individual event consisting of a rise of the current and flux along the hysteresis loop of Fig. 4 and their subsequent decay to normal values. The large current accompanying a single saturation is unidirectional; it cannot become a large reversed current until after the core density reaches saturation values in the opposite direction.

Referring to Fig. 2A (or Fig. 1A), assume the chance occurrence of a single saturation a short time after the supply switch is closed; the resulting unidirectional current must flow into the system capacitance since the unsaturated transformers will not pass any appreciable part of this current. The current flowing into the capacitance builds up a unidirectional capacitor voltage; this voltage continues to rise until the cycle of saturation is completed, at which time the transformer is restored to normal densities. With all of the transformers at normal densities, their impedances are too high to permit the capacitor to be discharged; consequently, the capacitance voltage will be maintained practically constant for the time being.

This action of a single saturation in the circuit is not unlike that of a valve; it injects a large current into the capacitance and then closes the entrance path to prevent its discharge. The magnitudes of the various changes resulting from a single saturation are dependent to a large extent upon the circuit constants, such as capacitance, normal transformer flux densities, size of core, number of turns, etc. It is not necessary to consider these factors at the outset because the fundamental nature of the phenomena may be explained on the assumption that a sufficiently large capacitance is present, and that saturations do occur.

Voltage changes resulting from the saturating process may be readily visualized with the aid of Fig. 5. The dashed-line curves in this figure may be recognized as the three normal line-to-neutral transformer voltages. Assume the switch to be closed at t_0 and that due to the initial conditions the transformer of phase 2 saturates at time t_1; in accordance with the preceding discussion, the saturation of phase 2 will result in an abrupt rise in the capacitance or neutral voltage. For the purpose of illustration this rise may be assumed as vertical. After the single saturation is completed, the high impedance of the transformers prevents the capacitance from discharging and for the time being the neutral voltage remains constant. However, the voltage which the capacitance has acquired adds to the voltage of phase 1 to result in an abnormally large voltage across its transformer. The large voltage, which in the figure is about twice normal, will saturate transformer No. 1 at about t_2. The second saturation is in the opposite direction to the first and consequently results in a reversal of the neutral voltage.

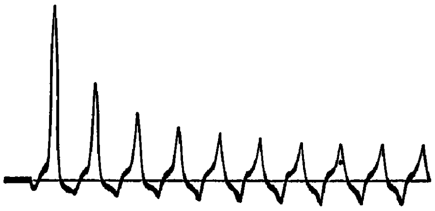

Fig. 3. Transformer starting current

In case it is not clear that the second saturation occurring at t_2 would reverse the capacitor voltage, reference is made to the hysteresis loop of Fig. 4. Once a saturation starts, it will increase in intensity until the transformer voltage reaches zero; so long as there is some voltage, the flux continues to increase. After the flux reaches a maximum, at the instant the transformer voltage reaches zero, it must decline to its residual value. This partial collapse of the magnetic field induces a transformer voltage in the opposite direction. Consequently in Fig. 5, whenever a saturation is assumed to occur, the affected transformer voltage should be reversed by an appreciable amount and the neutral and other voltages determined by subtraction and addition.

The neutral voltage acquired at t_2 remains constant as before, while the transformers operate in the range of normal densities. Again the neutral voltage results in an abnormally large voltage across the transformer of phase 1 and it probably will saturate at t_3 in the opposite direction. This saturation reverses the neutral voltage a third time and the process may be continued for the fourth, fifth, and sixth saturations; and so on indefinitely.

In essentials, Fig. 5 illustrates the origin of the abnormal voltages of this discussion, although the actual wave shapes obtained are not rectilinear. It is evident that the frequency of the voltages is dependent only upon the rate at which the saturations occur and it is not surprising that unusual frequencies have been observed.

At the start when there are wide differences between the core conditions of the three transformers, the saturations occur in a more or less hit-or-miss fashion and the resulting neutral voltages are highly irregular. As the initial differences in core conditions begin to be smoothed out, the time of saturation becomes more and more dependent upon how the neutral voltages combine with the supply voltages. For the voltages to reach a sustained condition it is necessary that some sort of stabilizing process be present which will maintain the voltages within a stable zone. This requirement is satisfied by the formation of multiple saturations or the saturation of two or more transformers in parallel and in the same direction. (Direction of saturation as used here has a very definite meaning when referred to either Fig. 1A or Fig. 2A. Two or more saturations are in the same direction when their respective currents flow in the same direction at the neutral; that is, either out or in.) The proper stabilizing multiple saturations occur only for a limited number of neutral-voltage frequencies,—namely, one-half of, equal to, double, and triple the supply-voltage frequency; consequently these are the only frequencies which can become stable and reach the sustained condition.

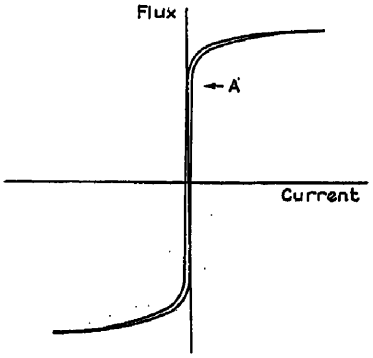

Fig. 4. Hysteresis loop

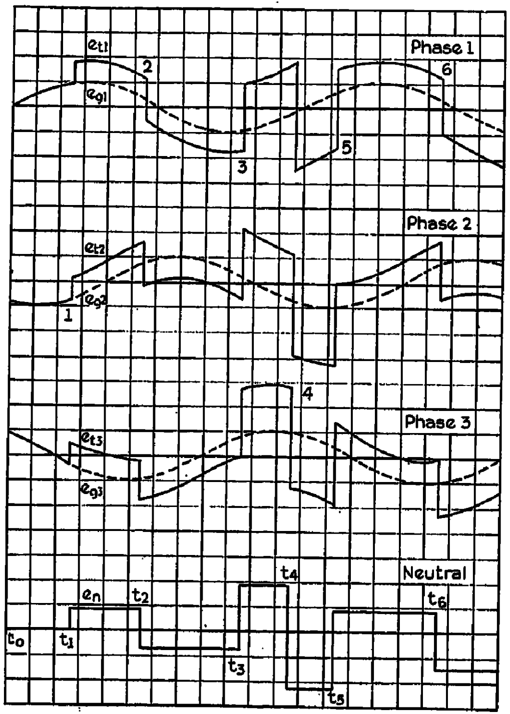

Fig. 5. Hypothetical voltages resulting from an arbitrary succession of saturations ($e_t = e_n + e_g$)

CONCLUSIONS

In accordance with the preceding discussion the abnormal voltages may be said to be self-excited by successive alternate saturations and limited in magnitude and frequency by multiple saturations. The complete theory based upon these two principles explains in an adequate manner the observed characteristics of the phenomena.

Graphical Construction of Hyperbolic Functions

By W. F. Helwig

Assistant Professor of Electrical Engineering
Texas Technological College

TRANSMISSION line calculations requiring the use of complex hyperbolic functions are materially simplified through the construction and use of a chart from which both the complex hyperbolic sine and cosine values may be determined in either polar or complex-number form. The device is a polar rectangular chart combined with a specially constructed scale graduated in values of $\frac{\epsilon^{a}}{2}$ and $\frac{\epsilon^{-a}}{2}$. The chart should be constructed with angles in circular radians and degrees which may be divided into convenient values. In constructing such a chart for practical use it may be convenient to employ heavy lines to denote each interval of 5 deg. and to subdivide these into degrees by fine lines. Ordinary cross-section paper having ten lines per inch is suitable for the rectangular chart.

Theory underlying the construction of the chart is given in the mathematical expressions:

$$\begin{aligned}
\cosh(a + j\,b) &= \frac{1}{2}\left[\epsilon^{(a+jb)} + \epsilon^{-(a+jb)}\right] \\
&= \frac{\epsilon^{a}\,\epsilon^{jb}}{2} + \frac{\epsilon^{-a}\,\epsilon^{-jb}}{2} \\
&= \frac{\epsilon^{a}}{2}(\cos b + j\sin b) \\
&\quad + \frac{\epsilon^{-a}}{2}(\cos b - j\sin b) \\
&= \dot{V}_1 + \dot{V}_2 \qquad \text{(plane vectors)}
\end{aligned}$$

Similarly $\sinh(a + j\,b) = \dot{V}_1 - \dot{V}_2$

PROCEDURE

Referring to the accompanying illustration, $O\,C$ is equal to $\frac{\epsilon^{a}}{2}$ and is laid off at the proper angle b on the circumference of circle S (this is $\pi/4$ or 45 deg. in the example given). Thus $\dot{V}_1$ is laid off in proper direction and magnitude. Next, the protractor, pivoted at the point C to the scale representing vector $\dot{V}_1$, is turned until its scale $\left(\text{graduated to values of } \frac{\epsilon^{-a}}{2}\right)$ lies at the angle $-\,b$ with the horizontal, or at the angle $2\,b$ with vector $\dot{V}_1$ in the clockwise direction. On this scale, at the required value of $-\,a$, the extremity of the resultant vector $\cosh(a + j\,b) = \dot{V}_0 = \dot{V}_1 + \dot{V}_2$ is found. It may then be read directly from the chart either in the form $A + j\,B$ or $C\,\overline{/\theta}$.

Obviously, the complex hyperbolic cosine may be determined from the same setting by taking the point $\frac{\epsilon^{-a}}{2}$ on the opposite end of the graduated scale along the diameter of the protractor. This is equivalent to reversing vector V_2 as required for the determination of the hyperbolic sine value.

sin h(a+jb)
cos h(a+jb)
Scale giving values of ½ E^-a from C, but marked in values of "a". Scale slides along pin "O".
Polar Chart

Polar-rectangular chart which simplifies transmission line calculations

This device is especially convenient in transmission line problems, since it gives both the hyperbolic sine and cosine at one setting, which values may be directly substituted in the equation:

$$\dot{E}_s = E_r\left(\cosh\dot{\theta}\,1 + \frac{Z_0}{\dot{Z}_r}\sinh\dot{\theta}\,1\right)$$

EXAMPLE

To test the operation of such a chart assume that it be desired to determine $\cosh\left(a + \frac{\pi}{4}\right)$ To do this, convert b to degrees and set scale S at the value 45 deg. Then move scale S along the pin at O until the proper value of a is opposite the pin. Next, turn protractor P through an angle equal to $2b$ (90 deg.) along S, and on the edge at a read the desired value.

The accuracy of the device depends, of course, upon the size of the chart and scales used. Experience shows that an accuracy of three significant figures may be obtained from a chart having an outside diameter of 20 inches.

Greater Efficiency for Low-Head Hydro

For heads up to 70 ft. it is predicted that the automatic adjustable-blade feature of the Kaplan propeller-type turbine is capable of producing at least ten per cent more kilowatt-hours.

By George A. Jessop *and* *C. A. Powell*

ECONOMY in first costs has stimulated 20 years of effort to secure a higher speed in hydroelectric units; principally because generator costs go down as the speed increases. Until recently an increase in speed has resulted in a reduction of efficiency—particularly at part loads—to a large extent offsetting the advantages of reduced investment. Improvement in generator efficiency with increased speed has only partially offset these reduced turbine efficiencies. Turbine designers now have succeeded in maintaining the maximum or peak efficiency at a given figure over a very wide range of specific speed, and by means of the Kaplan or automatically-adjustable blade runner have improved the part-load efficiency far above that formerly obtained even with slow-speed Francis turbines.

The relationship between specific speed and maximum efficiency is shown in Fig. 1; the specific speed of a runner is the rev. per min. at which a homologous runner will operate under a one-foot head when it is so reduced in size as to develop one horsepower under a one-foot head. Generally speaking, Francis turbines are used up to a specific speed of 110 and the adjustable and fixed-blade propellers for specific speeds above this figure. Fig. 2 shows a comparison between the peak- and part-load efficiency of turbines with specific speeds ranging from 25 to 150. The turbines with specific speeds of 25, 50, 75 and 105 are Francis turbines. Of the two turbines with a specific speed of 150, one is of the fixed-blade and the other of the adjustable-blade axial-flow type. It is interesting to note how the part-load efficiency drops off rapidly as the specific speed is increased—a defect which can be overcome by the use of the adjustable-blade turbine. The notable feature of this latter type is the fact that its efficiency over the entire range of output is high, exceeding even that of the lowest-speed Francis turbine at low loads.

Generator efficiency varies with the load, as shown in Fig. 3 where it may be noted that the efficiency increases with the size of the unit and also with speed. Because of the more marked effect of the windage losses at the higher speeds the part-load efficiency increases less rapidly than the full-load efficiency. Data similar to those given by Figs. 2 and 3 must be combined to obtain the satisfactory performance of the complete unit.

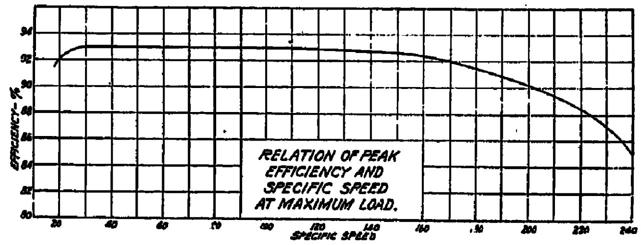

Fig. 1. Relation between specific speed and maximum efficiency

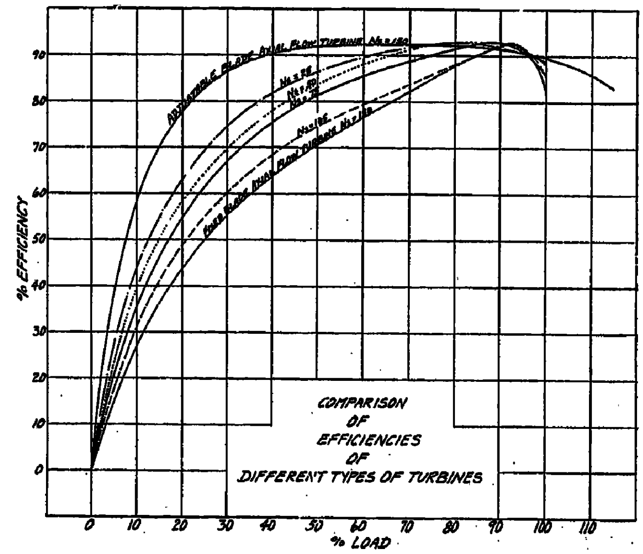

Fig. 2. Turbine load-efficiency curves covering specific speeds ranging from 25 to 150

From "Hydraulic and Electrical Possibilities of High-Speed, Low-Head Developments," presented at th A. I. E. E. Middle Eastern District Meeting, Philadelphia, Oct. 13-15, 1930. (No. 30-165.)

In Fig. 4 is made available a graphical method for determining the allowable relationship between head, horsepower, and speed. The head curves represented by full lines are to be used for Francis turbines, and those represented by dotted lines, for axial flow turbines. At the upper left-hand part of the chart, lines have been drawn indicating approximately the limits of capacity corresponding with the different heads. It is believed that this information will be useful for preliminary engineering work in connection with the designing and estimating of hydroelectric developments and the selection of suitable generator speeds. The limitations of specific speed set by this chart—that is, the combination of horsepower, head, and speed—are the results of many years of experience and at the present state of the art may be regarded as good practise. If plants are designed within these limits and with the proper relationship between the center line of the unit and tailwater, best results in output, economy, and long life are secured.

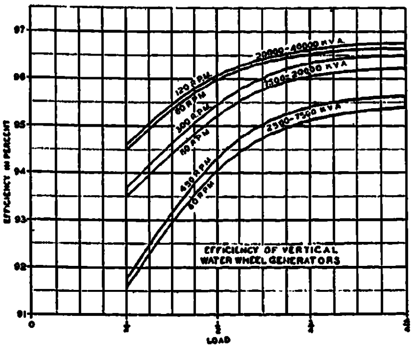

Fig. 3. Generator load-efficiency curves drawn on the basis of normal overspeeds

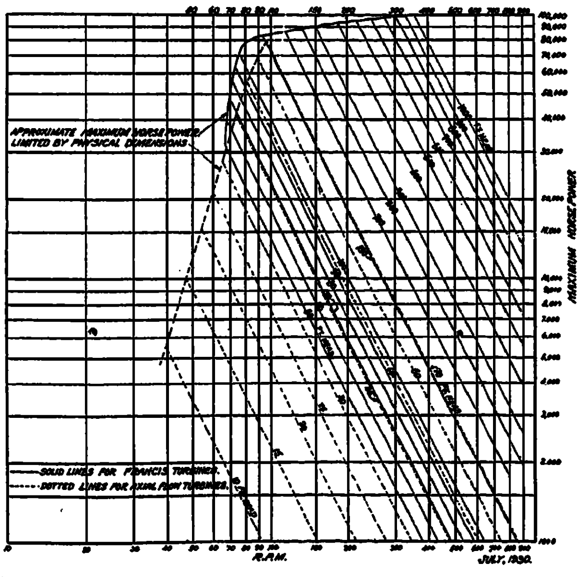

Fig. 4. Chart for graphical determination of allowabl relationship between head, horsepower, and speed

The field of application of the fixed- and adjustable-blade axial-flow turbine lies in relatively low head developments,—approximately 70 ft. or less. One of their great advantages is that they permit considerably higher speeds than the older Francis turbine.

Effects of increased speed on the first cost of the turbine are slight, but there is a definite trend toward reduction. The rev. per min. of a fixed-blade axial-flow turbine may be from 70 to 80 per cent higher than that of a medium-speed Francis turbine, but because the amount of water to be handled is the same in either case the reduction in cost will be approximately only 5 or 10 per cent. The small saving effected is incident to handling the water at somewhat higher velocities. From the generator designers' point of view, there is always an advantage in increasing the speed, because the cost of the generator goes down and the efficiency goes up. (Fig. 5)

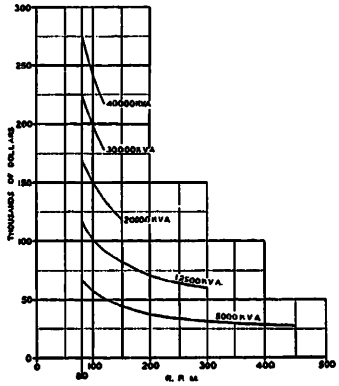

Fig. 5. Generator costs vary with speed and capacity

The cost of an automatically-adjustable turbine is substantially greater than that of a fixed-blade turbine, varying from 20 or 25 per cent for very large sizes to as much as 50 per cent for small sizes. However, this type shows a marked increase in kilowatt-hour output and consequently in earnings; and since the cost of the turbine in most cases is but a small fraction of the whole cost, the total investment is increased only a small percentage.

Excavation and power costs also must be considered in connection with the selection of a turbine. Turbines of high specific speed generally may be set at a lower elevation than those of low specific speed, thus tending to increase excavation cost. This tendency is counterbalanced to some extent by savings in superstructure and it is believed that increased earnings in every case will more than compensate for the greater investment.

As shown in Fig. 6 Kaplan turbine runners resemble a ship's propeller rather than a Francis turbine. Three important Kaplan characteristics are:

1. A vane-free transition space between the discharge area of wicket gates and runner entrance. Water leaving the gates in a whirling inward direction is deflected in this transition space to flow axially through the runner.

2. Wing-shaped runner vanes, so spaced and proportioned that two adjacent vanes form a nozzle or double guidance for part of their radial extent and single guidance for the remainder.

3. Adjustable runner vanes.

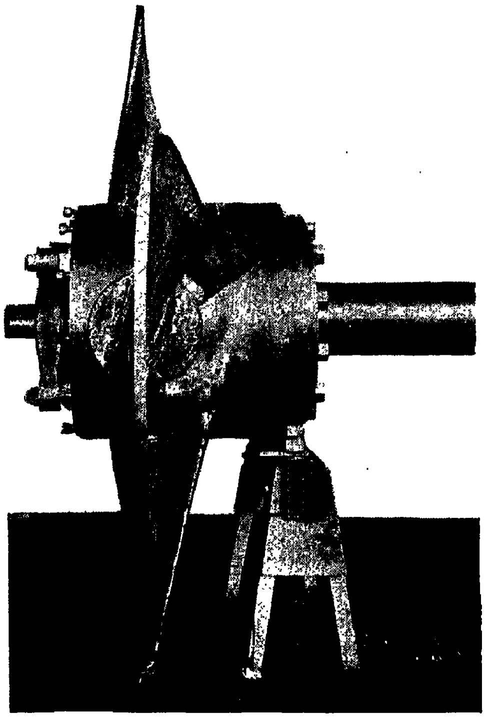

Fig. 6. Axial-flow turbine with adjustable blades open

Professor Kaplan was the first to adjust the runner vanes and the wicket gates simultaneously. This maintains the best conditions of flow throughout the entire range of output and results in high part-load efficiencies, thus securing flat efficiency-load curves. Each position of the runner vanes corresponds to a definite position of the wicket gates, and if the efficiency at all rates of discharge is to be maximum the correct relationship of these positions must be maintained. Since the blade and gate angles and openings always have the correct relationship to each other, the adjustable-blade turbine operates with maximum smoothness and with minimum vibration and pitting. Turbine casings are constructed with the usual wicket-gate casing except that the top plate contains an inverted, curved, cone-like projection which forms the inner surface of the transition-space.

All of the operating connections for moving the vanes are contained inside the single-piece hub casting, (Fig. 7), and are of such form that without any adjustment they will stand up indefinitely under the most severe service requirements. To guarantee freedom from excessive strains and to reduce the possible wear to a minimum, stresses are held within conservative limits. To resist wear, bearings for the runner-blade stems and the links are bushed with bronze, and special provision is made to secure the blades against lateral displacement due to the large centrifugal forces developed. To provide constant lubrication for all moving parts, the hub is filled with a heavy-body oil and each runner-vane trunnion is packed to eliminate oil loss.

To synchronize gate control and runner-vane control, each has its own servo motor and distributing valve. The regulating rod in the hollow turbine shaft is moved axially by a servo motor (Fig. 8) arranged between the flanges of the turbine and generator shafts and rigidly connected to them to revolve with the shaft. The servo motor piston is connected directly to the upper end of the regulating rod which communicates the piston movements to the runner vanes. The servo motor is operated by oil supplied under pressure through two pipes arranged concentrically within the hollow generator shaft. The two pipes terminate in two distributing chambers mounted one above the other on top of the generator. These chambers receive the oil from the governor and collectively form the oil supply head. The governor itself is the usual speed governor which operates the wicket gates either through a vertical gate shaft or through servo motors.

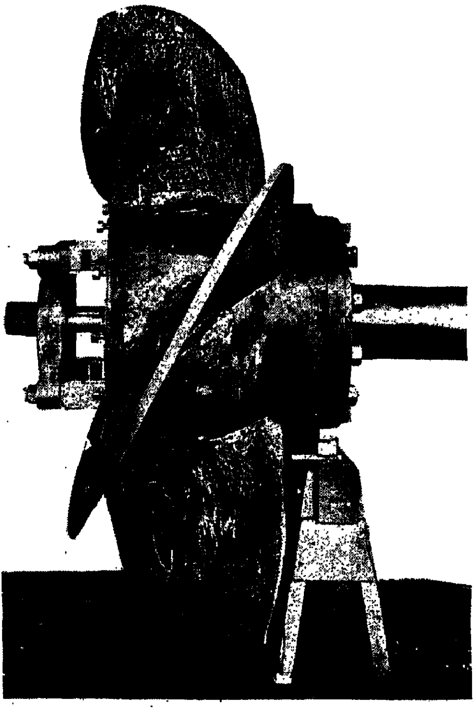

Fig. 7. Axial-flow turbine with adjustable blades closed

The field of application of the umbrella generator is for the large low-head units; and because of its inherent advantages, it is used wherever possible.

To determine the effect of the characteristics of various types of hydroelectric units on yearly plant output, a kilowatt-hour output study is given in Fig. 9. For purposes of illustration, a three-unit development was chosen and a comparison made between three medium-speed Francis units, three fixed-blade axial-flow units and three automatically-adjustable-blade axial-flow units, each rated at 28,500 kw. at extreme full load under a 53-ft. head. The adjustable-blade turbine has a surplus of 15 per cent above the maximum capacity of the other units, and reference to Fig. 2 shows that the adjustable-blade turbine can be selected to have this surplus capacity and still have the part-load efficiency. Even with surplus capacity, the physical dimensions of the adjustable-blade turbine are smaller, and generally speaking, it is possible to operate it at a higher speed than a fixed-blade unit. In Fig. 9 it may be noted that the adjustable unit is operated at 109.1, the fixed-blade unit at 100, and the medium-speed Francis unit at 58 rev. per min. Generator costs for the adjustable units thus will be somewhat less than for the others.

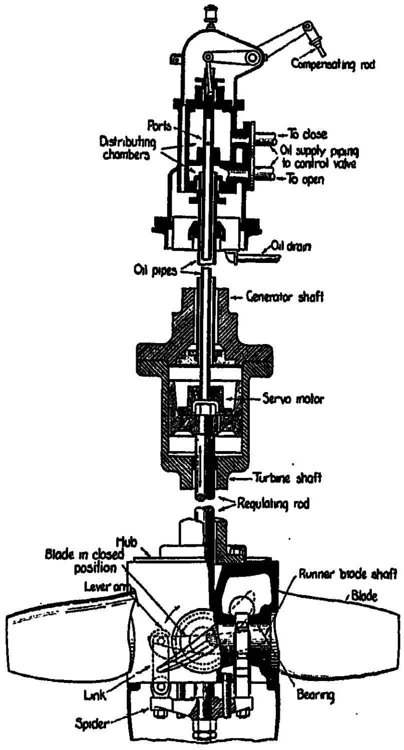

Fig. 8. Assembly and operating scheme of adjustable-blade axial-flow turbine

The kilowatt output was worked up from the head and second-feet available, starting with one unit running, and changing to more units as soon as additional kilowatts can be obtained by so operating. It has been assumed that if desirable from the standpoint of economy in the use of water, each unit can be operated to maximum load and there is no necessity for maintaining a surplus for speed regulation.

It is of particular interest to note that the adjustable units produce 11 per cent more kilowatt-hours than the fixed-blade units and that the Francis and the fixed units have about the same yearly output. If it is necessary to maintain a certain operating reserve, the adjustable units will prove to be even more advantageous than shown, because it will be necessary to operate the Francis and fixed-blade units at even a lower load and consequent lower efficiency for part of the low-flow period. Head and second-foot duration curves are different, of course, for each development and it is necessary to make a special study for each case.

Two types of generators are suitable for use with this turbine; the more general two-bearing design, in which the thrust bearing and one-guide bearing are located above the rotor with the second-guide bearing below the rotor; and the umbrella design in which the single combination thrust-and-guide bearing is located below the rotor. In cost and efficiency there is practically no difference between the two designs, but the umbrella design requires less head room under a crane and is easier to dismantle. Its single bearing runs in a bath of oil, obviating all oil piping, and it lends itself readily to convenient ventilation. If a direct-connected exciter is not used, the upper bracket may be omitted entirely—of advantage in reducing building superstructure.

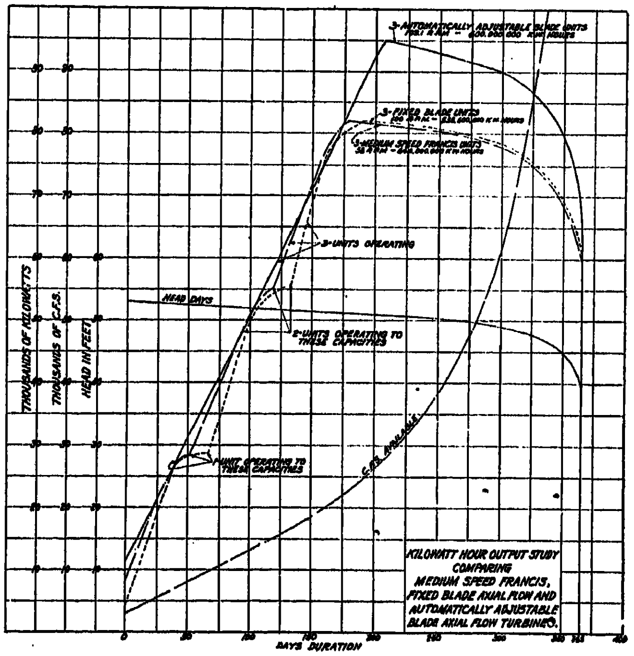

Fig. 9. Output comparison of a three-unit station equipped with three different types of wheels

The field of application of the umbrella generator is for the large low-head units, and because of its inherent advantages, it is used wherever possible.

Detecting Hidden Fissures in Rails

Greater track safety is being accomplished by railroads through the use of a special electrical device which reveals, marks, and classifies dangerous flaws in rails as a test car progresses along the track under test.

By H. C. Drake

Sperry Products, Inc., New York
Associate, A. I. E. E.

"IN THE OLD DAYS" it was not infrequent for flaws in railroad track rails to show up after the wreck. Visual inspections revealed cracks and surface fissures, but hidden fissures—often the most dangerous—remained undetected until the recent perfection of electrical equipment and development of a routine testing technique.

Transverse fissures in rails are fatigue failures of internal origin, whose rate of growth depends largely upon the density of traffic. The typical air-tight fissure has a characteristically bright, silvery appearance produced by the peening action of the fissure faces when the rails are subjected to the impact of heavy wheel loads.

This type of failure was brought to the attention of railway engineers some nineteen years ago when a passenger train was derailed by a rail which broke into seventeen pieces, disclosing a fissure at every fracture. In the years which followed, rail failures due to transverse fissures were reported in ever-increasing numbers. The presence of large transverse fissures in relatively new rails under the best conditions of track maintenance, together with the utter impossibility of seeing or locating such fissures, placed the cause of failure in the class with a cyclone, a lightning stroke, or other "act of God."

In the early part of 1927, internal fissures in rails were successfully detected at the laboratory by the electric method, and after several months of experimental work a fissure-detector car was constructed for the American Railway Engineering Association. The car passed its acceptance test and was placed in testing service on the railroads of the country in November 1928.

For its operation the fissure detector depends upon the fact that electric current flowing through a rail is compelled to pass *around* any fracture, inclusion, or separation in the metal. When a rail is sound the axis of current is substantially straight; but if a fissure is encountered, the current axis at that point is displaced. An inductive pick-up device is mounted directly over the rail head where it cuts the magnetic lines of force surrounding the rail. In the case of a sound rail carrying current, the magnetic flux surrounding the rail is uniform and as the inductive pick-up passes along, no e. m. f. is generated; but when the axis of current is deflected, as at a fissure, the flux density around the rail varies, resulting in a generated potential at the terminals of the pick-up. This output from the pick-up is amplified and led through relays connected to recorder pens, thus giving a record of the impulse received.

In applying the electrical method of fissure detection to inspection of rails in tracking, the following factors materially affect the final design:

1. Many spots are encountered where locomotive drivers have slipped in starting and have gouged out the rail.
2. Worn or flat spots occur frequently, especially opposite rail joints.
3. In certain stretches of track, rail surfaces have acquired a pronounced ripple,—termed corrugated or washboard rail.
4. Frequently the rails are covered with a hard insulating film, the resistance of which may run up to several thousand ohms.
5. The gage of the track varies between certain limits.
6. Rail surfaces may be level or canted.
7. Rail sizes vary from 70 to 130 lb. per yard.

The single-unit type of detector car is 45 ft. long, self-propelled, equipped with extra-heavy frame and axles, and when running to and from work, is capable of a speed of 45 mi. per hour. Just back of the driver's compartment are located the cook's galley and comfortable living quarters for the crew; and back of the living quarters is the compartment containing the power plant of the detector equipment. At the rear of the car is the operating room. The power plant consists of a specially-designed double-commutator, 6,000-ampere, two-volt, d-c. generator direct-connected to a 50-hp. four-cylinder gasoline engine. An exciting generator and an air compressor are driven also by this engine. Current from the two-volt generator is carried by heavy buses to the brush units under either side of the car.

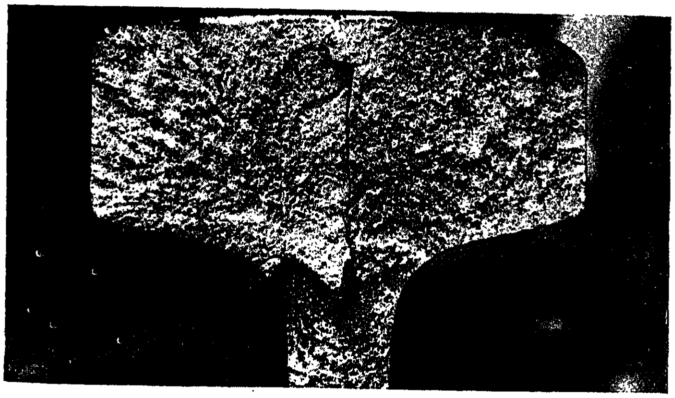
This brush-unit assembly consists of two sets of eight solid phosphor-bronze brushes mounted about three feet apart, rigidly connected by a cast frame, and supplied with individual springs which insure a pressure of 50 lb. per brush. Flanged wheels at the ends of the brush-holder engage the rail when the brushes are down and because of their angular mounting, cling to the gage side regardless of varying track conditions. Brush units are applied to the rail by air-operated pistons electrically controlled from the operator's switchboard. If the driver attempts to back up while they are on the rails, a safety switch connected to the gear shift of the car drive automatically lifts these brushes.

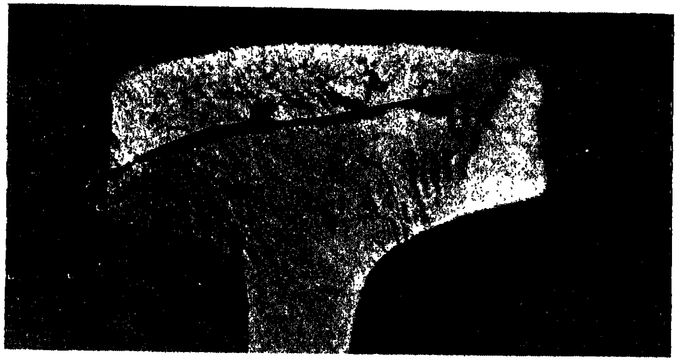
Brush-contact resistance has been found to be greatly reduced by the use of water on the rail; hence provision has been made to carry a sufficient supply of water for this purpose and to apply it automatically to the rail when the brushes are lowered. Mounted

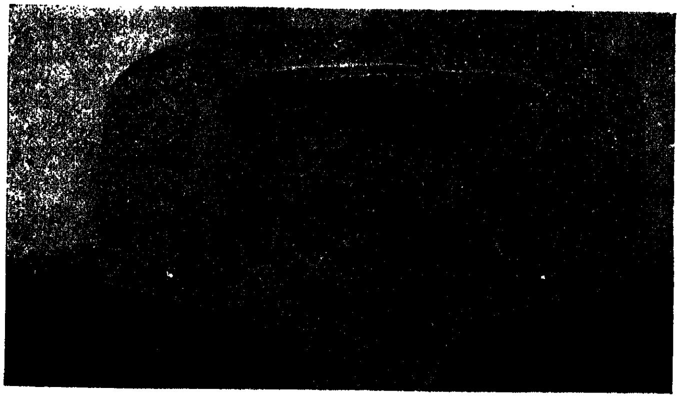
---

Presented at the Winter Convention, New York, Jan. 26-30, 1931. (No. 31-28)

between the brushes is a separate carriage upon which is supported the pick-up unit; this carriage with its eight wheels and swivel mounting holds the pick-up unit at a fixed distance above the rail, riding over burns and flat spots without interruption. At first the driver burns and flat spots gave indications which tended to slow the testing; but that source of trouble was reduced materially by the eight-wheel mounting. Recent improvements in pick-up devices eliminate indications from flat spots and all but the largest of the burns.





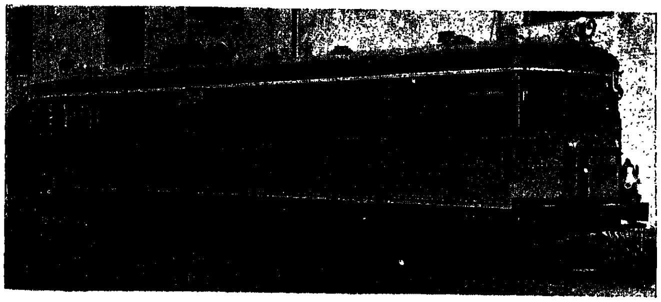


Typical fissures found in railroad track rails; (lower) the internal fissure, (center) a horizontal head fissure, and (upper) a split head. The electrical testing device infallibly locates these under service conditions

The operating room at the rear end of the car contains the recording table and control board as well as amplifying equipment and batteries. The output from the pick-up unit is brought up to a four-tube amplifier which is properly shielded and protected from shock. Three recorder pen relays are connected to the output of the amplifier and adjusted to respond to different values of plate current, thus giving an indication of the size of the defect detected. Other relays are provided to operate paint guns so that the fissure location will be marked automatically by a spot of paint on the rail or tie.

As shown in an accompanying illustration, the record is made up of nine lines, resulting from as many pens, which indicate the relative size of each fissure and the rail in which each is found, the passage of each rail joint, and the passage of each identifying landmark. Joint cut-outs mounted on the brush-holders engage the angle bars and cut out the fissure pens and paint gun at each joint, at the same time operating the joint pens. The landmark pen is operated from the car driver's switchboard. He presses the button whenever a mile post, bridge, signal tower, or other landmark is passed, and the operator at the recording table stamps in the proper designation.

In operation, the car passes along the track at approximately six miles per hour with from 2,000 to 3,000 amperes flowing through each rail, the current value depending upon the weight of rail being tested. The operator seated at the recording table in the rear of the car has before him both the record chart and a clear view of the tested track. When the car passes over a fissure, an indication appears on the record and the defect is marked automatically with a spot of paint. The operator notes the record, sees the paint mark on the rail, stops the car and backs it up to the paint mark for a hand test of the suspected spot. For the hand test a current of 1,500 amperes is induced into the rail by means of air-operated contactors and the unit IR drop is measured with a galvanometer. By means of this test the size of a transverse fissure can be determined within a few per cent.

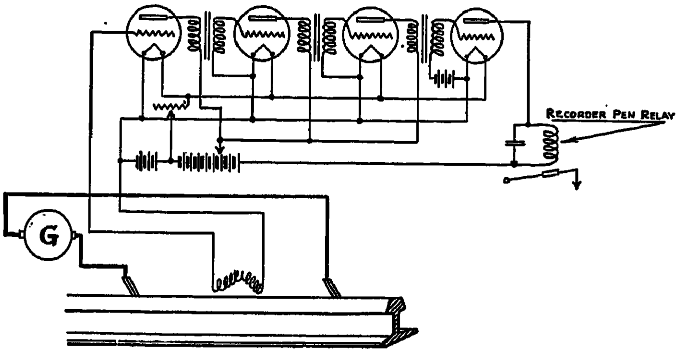


A self-propelled detector car; brush and pick-up units mounted between trucks

The detector car locates not only transverse fissures but split heads, horizontal fissures, compound fissures, pipes, cracked webs, broken bases, and other defects. When a defect is located by the car the first question asked by the railroad representation is, "will it be safe to leave the rail in track until there is a lull in the day's traffic, or must the next train be tied up while the rail is replaced?" The answer to this question lies in the result of the hand test. When the hand test shows no transverse crack the rail is marked for removal at the next opportune time; but if a large transverse fissure is indicated, the railroad takes no chance but removes the rail at once.

Although the testing speed of the car is six miles per hour, there are many elements which enter in to limit the total mileage tested per day:

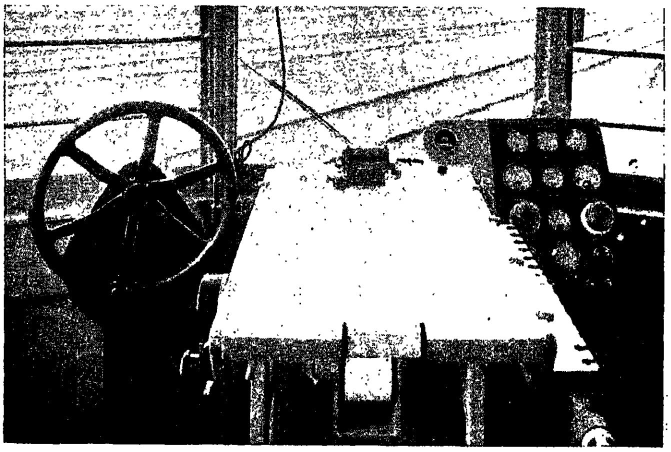
1. Traffic delays due to clearing for trains frequently consume considerable time, but are unavoidable.
2. When a fissure is located the railroad representatives always makes a record of the manufacturer, the year rolled, ingot letter, and heat number of the rail. If the rail has been in track for several years or has been oiled by the track oiler, it is often difficult to locate and decipher the heat numbers and it is not at all uncommon on some roads to have from five to fifteen minutes wasted in obtaining the rail data.
3. A repeat run over a suspected rail takes thirty seconds, and from two to three minutes are necessary for a hand test.



A main bush and pick-up unit; flaws in the rail disturb smoothness of current flow between brush sets, resulting in electromagnetic disturbances which are pick d up by the central device and recorded in the car

Testing procedure on the ten cars now in service is practically identical, but railroads differ somewhat in methods of conducting the test. A survey of the various methods employed indicates that the following procedure results in a minimum loss of time.

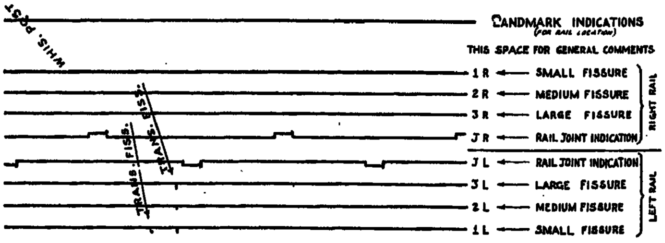
The railroad has one man on the car and one on a hand car which follows the detector car. In addition there is of course a conductor and a flagman. When an indication is recorded the car is stopped, a check run made over the suspected rail, and the car backed up for a hand test. The operator examines the rail and if his visual inspection discloses exterior evidence of a split head, horizontal fissure, or other defect, he gives the word to the railroad man, who makes a red paint mark on the tie at the defective spot and chalks the identification number on the rail. If no visible defect is noted, the hand test is made and the rail is marked as before.



Recording table and control board; the operator can watch the track as well as his instruments

The car then proceeds with the testing while the man on the handcar stops to record all of the data, together with the location of the rail, and then continues on after the test car. In this way the maximum time lost by the major equipment and crew is the two or three minutes required for hand testing.

Two years have passed since the first detector car was placed in service and during that time many interesting fissure facts have been accumulated. A single rail has been found to contain as many as 24 transverse fissures. Fissures have been found in rails 28 years old, and in rails five months old. Many consecutive miles of track have been found to be free of fissures while other short stretches have had from 20 or 30 fissures per mile.



A typical record made by the detector car equipment

While these isolated cases are of interest, the most important point is that the transverse fissures are now being located and removed from track before they can cause damage, whereas prior to two years ago their presence was not even known until they had grown to the surface, or broken the rail.

The Engineer's Duty to Himself and to the Public

The engineer is the one person best qualified to know the vital facts underlying any great project and to interpret their true significance. Upon him, therefore, rests the responsibility of enlightening the general lay public as to the difference between engineering facts and political expediency, particularly where public monies are involved.

By William S. Lee

President, A. I. E. E.

TO DETERMINE the public duty of the engineering profession it is necessary first to understand the engineer's relation to the public. It is an ideal of the Institute that the engineer shall endeavor to assist the public to a fair and correct general understanding of its engineering needs; to ascertain the general knowledge of engineering; and to discourage the appearance of untrue, unfair, or exaggerated statements on engineering subjects in legislation, the press, or elsewhere—especially if these statements may lead to or be made for the purpose of inducing the public to participate in unworthy or unsound enterprises.

When a project of any magnitude is contemplated it is customary to employ engineers familiar with that particular line of work and to submit the problem as a whole to them. After a thorough study of conditions these engineers plan the best layout or design for the project, organize the necessary man power, purchase materials and equipment and ultimately build the project, often organizing the entire operating forces required for its functioning. Thus the engineer is the one person best qualified to know all pertinent details of his project; to evaluate them properly and correctly.

Unfortunately for the public at large, unbiased and fundamental engineering information on major projects seldom is broadcast to the public concerning public or quasi-public projects. In the inevitable financing of any project it is usual that only a few of those involved are well informed. If the project be one in which large numbers of citizens participate in public financing, the engineers' reports seldom if ever penetrate beyond the inner circles, except perhaps in modified form. If the project be one which can be handled with the financial assistance of but a few persons, still only a small group gets a real, direct understanding of the importance of the engineer's position and advice. The result is that great projects are designed, constructed, and put into operation by but few members of the great general public which in the long run pays all the bills.

Consider for a moment those wonderful and enormous projects which you have seen completed by engineering ingenuity in the last two decades. Great organizations and great masses of men and material were mobilized for the purpose by "that army from God knows where."

"No bands were gaily playing,
  When they were going into action;
No crowds were madly cheering
  Their deeds of daring do.
They were owing small allegiance
  To any flag or faction;
Their color was on the sky-line
  And their war-cry put it through."

If the engineer is capable of designing, constructing, and operating these projects, he certainly should be taken into the confidence of the public. His assistance should be invaluable in advising the public as to policy in regard to these developments which play such an important part in the growth and well-being of our country.

It is my wish to emphasize the urgent duty of the engineer not only to convince his brother engineer that his design, construction, and operation are right, but to advise the public to the end that it may be adequately and accurately informed; that it may see the fallacies of half-baked political theories, and may avoid developments that would be prejudicial to the public interest. The American Institute of Electrical Engineers always has emphatically insisted that in all his relations the engineer should be guided by the highest principles of honor. It holds that it is the duty of the engineer to satisfy himself to the best of his ability that the enterprises with which he becomes identified are of legitimate character.

We in America are confronted today with a situation that is fraught with danger, because of the fact that the public may, through partial or insufficient knowledge, reach erroneous conclusions and undertake developments (legislative or otherwise) that would result in our government entering business in competition with its citizens and thus embark upon a course disastrous to the best interests both of those directly affected and of the taxpayers of the country in general. That is why I am urging the engineer, who is trained to consider only facts and absolutely true and complete conditions, to

---

An address delivered before the opening session of the A. I. E. E. winter convention, New York, Jan. 26, 1931.

use his efforts in giving the public the correct picture. An engineer's experience has led him to realize that nothing ever is as good as it appears on first blush and that nothing ever is quite as bad as it first looks. It is the engineer's lot to study a problem with an unbiased mind; to analyze thoroughly and honestly each particular phase of every situation in order to give his client the proper advice. The present national situation is a challenge to the best ability and professional ethics of the engineer—*each engineer*.

President Hoover is fundamentally opposed to governmental industrial ownership and operation. He set this forth very clearly in his concluding remarks in 1924 when, as Secretary of Commerce, he said:

> We are asked to embrace new social ideas, increase our cost of service, decrease our national efficiency, and thus destroy the fundamentals upon which our nation has become great. This is not progressive, for it is not progress. It is destruction.

Ex-president Coolidge in "Calvin Coolidge Says" on January 6, 1931, said in part as follows:

> For wage earners to benefit in time of general depression it would be necessary to assume that government ownership would prevent fluctuations in the business in which it engages. If it is assumed that payment of wages will go on without work, that is not employment, but relief. Then no one should work.
>
> The government has never shown much aptitude for real business. The Congress will not permit it to be conducted by a competent executive, but constantly intervenes. The most free, progressive, and satisfactory method ever devised for the equitable distribution of property is to permit the people to care for themselves by conducting their own business. They have more wisdom than any government.

There are many problems confronting the people of America with regard to public utilities, and especially those utilities that have to do with the generation and distribution of electricity. It is through the engineers I believe that a true and proper study of these problems should and will be made. If the varying tide of sentiment for political or public ownership in this country is based upon correct economic and business principles, the theory should be developed and proved, rather than hurried into existence by retaliatory legislation, an over-persuasive press, or communities that are rightly or wrongly disgruntled.

I cannot refrain from emphasizing the vital necessity of exercising the utmost caution and care in the consideration of these problems. Public ownership in this country and in others, as it has been developed up to this time, by no means has proved that it deserves the support of the people at large; in some instances there have been apparent momenetary advantages, but, in the long run, experience has demonstrated the futility of the arguments of those who favor political or public ownership.

For instance, it has been argued that through the exercise of government financing electric power plants and distribution systems could be constructed with cheaper money. However, it is a well-known fact that construction projects under government supervision generally cost at least twice as much as contruction projects under private ownership, thus eliminating any advantage from this source.

Again, under political or public ownership and operation those properties concerned usually do not pay taxes and the revenue that might be derived from them is of necessity transferred to other sources of taxation. This is a matter of such great public concern that in some states a well-defined movement is under way looking toward the taxing of municipally owned utility enterprises.

In this great country today we are polluted with too much political engineering, political banking, political railroading, and other similar infections too numerous to mention. I think, one of the most dangerous situations that today confronts the engineering fraternity and the public is the mad rush of certain sections to go into political, state, or municipal ownership.

It is the engineer's duty to the public, in these days when there are so many public or quasi-public operations, to make available his judgment and advice so that the people at large may have the advantage of it in arriving at intelligent conclusions in these matters.

It is necessary in this discussion to consider some concrete case: Take the much discussed Muscle Shoals development; why was it built? Does anyone know? Certainly not as a war measure for its actual construction began after the war was over. The nitrate plant located there had constructed a steam plant of a size capable of operating it. This steam plant was within two or three weeks of completion when the Armistice was declared. Why did the government *the next year* begin the construction of Muscle Shoals? I knew and you knew then just as well as we know fifteen years later that it was an unsound venture.

About 1921 the United States government, through its chief of engineers, notified the various power companies and possible power consumers of the South to investigate Muscle Shoals and see if they would be interested in securing power from it through some mutual arrangement. I made a very complete and detailed investigation of this plant, its costs, amounts of power, and other vital points and in a signed report dated May 18, 1921, covering all these matters (a copy of which was sent to the United States Chief of Engineers) my conclusions were given as follows:

> 1. The amount of power estimated by the designing engineer on this work is not correct, nor can it be developed there for practical use. Power cannot be sold as primary power on the basis of average monthly stream flow. Four months' secondary power has no value at present; therefore, the amount of revenu will be materially less than estimated.
>
> 2. Present use of power in the Southern district does not develop more than 50 per cent load factor. The navigation problems incident to this development are such that this plant will have to be run at approximately 100-per cent load factor in low-water season or waste the water.

3. Total cost of this development will be $56,500,000. The additional cost over the present expenditures will be approximately $40,500,000. The plant when completed is not worth $30,000,000.

4. Transmission of power to the systems of the Southern Power Company and the Georgia Railway & Power Company cannot be done in competition with power from other sources.

5. Power transmission to the systems of the Alabama Power Company or the Tennessee Power Company on the same basis as proposed by the designing engineer would cost these companies twice what they can develop their own plants and produce it for.

6. There is no present use or need for this development.

7. The permanent work that has been done should be left as it is, the construction plant salvaged, and the completion of this plant not undertaken until there is developed some use of the power which will require from 80-per cent to 100-per cent load factor.

8. Except for a small amount of power that could be sold to the companies operating near this plant, it would stand idle for years, with no use for the power.

9. The loss in discontinuing this work and waiting until some use for power can be developed will be small as compared to the loss of investing a large amount of money in the plant and letting it stand idle for years.

10. There is no way at the present time that the United States government can get anything approaching a reasonable return on this development if completed.

11. None of the power companies could afford to purchase power under conditions proposed by the designing engineer, and six of the eight could not afford to purchase at any price, because they can develop or procure their power from other sources at a less price than it will cost to transmit the power from Muscle Shoals to their territory.

My reason for discussing Muscle Shoals is the fact that it involves two great principles of the deepest significance to the whole country, industrially and politically:

First, should the government go into business? The more people that work for the government the nearer we approach socialism. I cannot believe that this country is ready to go into socialism; hence why should we be pursuing this policy? The greatest factor in the development of America has been American initiative—and certainly when the government goes out and competes with its citizens in business the great American initiative will be destroyed. Why should a few members of our government persuade the people to set up competition with its citizens when the citizens actually comprise the government? Why should an organization created by the people be endeavoring to destroy the people?

Second, if business is in politics every detail will be the subject of terrific political harangue and investigation.

A review of some of the estimates of cost for Muscle Shoals is startlingly revealing. The development was estimated in April 1920 to cost $23,800,000—say 25 million. Within less than a year this estimate was changed to 50 million; now, the plant has been partially completed and the cost is approximately 47 million and about half of the generating and hydraulic equipment for the powerhouse remains to be completed. A private corporation would have built the same plant for less than half that cost.

For any hydroelectric plant to be successful, be it government or private, it must be able to compete by selling power at a cost equal to or less than that produced elsewhere. Muscle Shoals has less than 100,000 hp. in primary power. In fact, for many weeks during the past year this was less than 65,000 hp. Now, if this plant already has cost approximately 47 million dollars and is still incomplete, it is futile to think of its competing on any kind of a business basis against other sources of power. No doubt many will say that there is a considerable block of secondary power; this is true, but to utilize the secondary power a steam plant must be built, with resultant interest, depreciation, taxes, and part-operating expenses to be provided for. After provision is made for these charges incident to keeping such a steam plant in condition for service, the additional cost of fuel and part-operating expenses with a modern steam plant will be so low that secondary power from Muscle Shoals will not be attractive.

Would any private corporation enter into such a venture? An estimate of approximately 50 million dollars and plant not complete, almost fifteen years since the project began, no contracts made!

There is no doubt that Muscle Shoals has been a colossal political and governmental blunder, but I fear that the next decade will see even greater blunders if some of the projects which are under way now, or projected, are constructed. If Muscle Shoals, begun nearly fifteen years ago, is today earning nothing and has no policy, what will occur at Hoover Dam? There is a tremendous development started, and nobody knows where it is going. An enormous project already started from the funds of the taxpayers, but without tangible evidence of any definite policy or effective contracts. It is time that these matters be discussed honestly and more frankly by the engineering fraternity with the public to obviate the continuance of these terriffic blunders.

Right in the Greater New York area is the greatest aggregation of engineers in the world, and yet serious consideration is being given by the state government to the building of the Long Sault plant on the St. Lawrence River. Every engineer knows that the government costs of constructing that plant will be two or more times what private costs would be. Further, we know that it is impossible to transmit the power from the St. Lawrence River and make it available to the City of New York in competition with modern local steam plants. It looks as if the public is being ballyhooed for another Muscle Shoals, only on even a more gigantic scale.

Engineers have contributed largely to the remarkable progress that has taken place in the electrical field during the past four decades. The progress in this field has been responsible in a very large measure for the wonderful development of industry in America during that period. We engineers are proud and grateful that we have been able to have a hand in the remarkable progress which America has made during these years; and we should be deeply concerned that no obstacle be allowed to slow down or handicap the economic development which means so much to the American people, from the well-to-do down to the humblest working man.

Hence I protest against this dangerous tendency of the day, and I say to each and every one of you engineers, it is your duty, and mine, both to ourselves and to the public, to use our best efforts to see that the public is correctly and properly advised, for when so advised their conclusions will be sound. For,—

'Tis a coward that quits to misfortune,
'Tis a knave that changes each day;
'Tis a fool who wins half the battle,
And then throws all his chances away.
There is little in life but labor,
And tomorrow may find that a dream,
Success is the bride of Endeavor,
And Luck but a meteor's gleam.
The time to succeed is when others,
Discouraged, show traces of tire;
The battle is fought on the home stretch,
And won twixt the flag and the wire.

◆ ◆ ◆

Control Groups Simplify Operation

Unit arrangement, grouping closely around each hydroelectric generating unit all of its associated electric switching and control equipment, accomplishes important economies as well as providing improved operating flexibility and ease of expansion. Radical departures in practise have been combined with others of more usual characteristics to achieve an attractive combination.

Member, A. I. E. E.

ELECTRICAL features constituting the control of the Ohio Falls hydroelectric station of the Louisville Gas & Electric Company represent a distinct advance in the art of utilizing well established principles combined in a unique fashion. Thus an initial installation cost lower than usual has been achieved as well as basic provision for extensions which can be made in a most economical fashion from time to time. The design of the station is particularly unique in the fact that each generating unit is complete in itself; water-wheel, generator, exciter, governor, electrical control, and oil circuit breakers are individual to each generating unit, and all related unit auxiliaries are fed entirely from that unit, with but few exceptions. The four points that are retained in common and which reflect the more usual design are (1) forebay, (2) high-voltage buses, and (3) centralized coordinating control for the station.

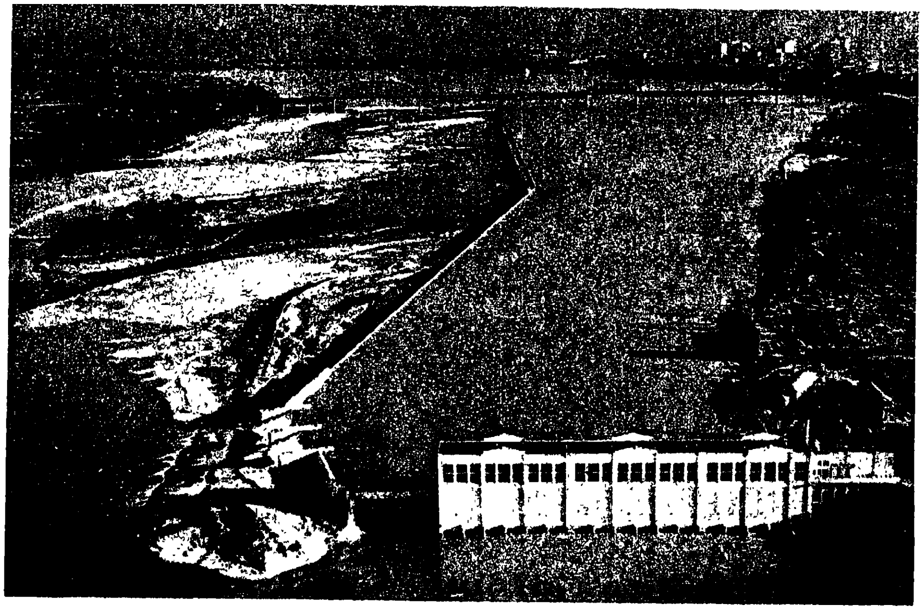
Each of these features may of course be recognized as embodying well established principles, but the prominent characteristic of the Ohio Falls station lies in the fact that in it are utilized simultaneously, all of these combined to the best advantage. The design is characteristic of simplicity, practically all conduit and wiring as usually encountered having been completely eliminated.

One of the basic ideas was an electrical control unit corresponding to the hydraulic control unit, situated near each generating unit. This feature has been accomplished by grouping all of the electrical control features and placing them inside a cubicle located just adjacent to the governor. But while this concentration of electric and hydraulic control is particularly desirable as far as installation is concerned, it did not seem to solve the problem of economical operation. Therefore a centralized supervisory control was incorporated, with a single multi-conductor telephone cable between it and each generator control unit. This arrangement happily accomplished centralized supervision and control of all units, at the same time reducing to a minimum the number of wire connections between the central control point and the controlled cubicle.

Because of the lower inspection and maintenance expense, operating as well as fixed costs are reduced. Substitution of the miniature switchboard and low-voltage, multi-conductor, lead-covered control cable for the usual large central control board and 19/22 control cable and iron conduit is principally responsible for this improvement. Further saving was realized in

---

From "The Ohio Falls Hydroelectric Station at Louisville, Ky." (No. 30-188) presented at the A. I. E. E. Southern District meeting, Louisville, Ky., Nov. 19-22, 1930.



Ohio Falls hydroelectric plant of the Louisville (Ky.) Gas & Electric Company; City of Louisville in the background. This project was built in cooperation with the U. S. Government in connection with its navigation and flood-control development of the Ohio River

obviating the cost of building, heating, and maintaining a control room of the usual proportions and location.

As new 4-, 13.2-, 66-, or 132-kv. feeders and related switching equipment may be required, they can be installed in the yard adjacent to the plant and unit-type switchboards, either singly or in groups, may be placed near the equipment to be controlled. To provide supervision for the new equipment the miniature switchboard can be extended four inches at a time to accommodate low-voltage multi-conductor cable installed as needed between the miniature board and the unit switchboard at the apparatus; and since the original plant layout need not be disturbed, this may be done at a minimum cost. Another important benefit realized in this station is that such extensions and additions do not involve the danger of work around operating equipment; the hydro station will not be cluttered with construction tools and debris; and station operation will not be jeopardized by work being done on control wiring and conduits located near active equipment, as was customary under the old order of things.

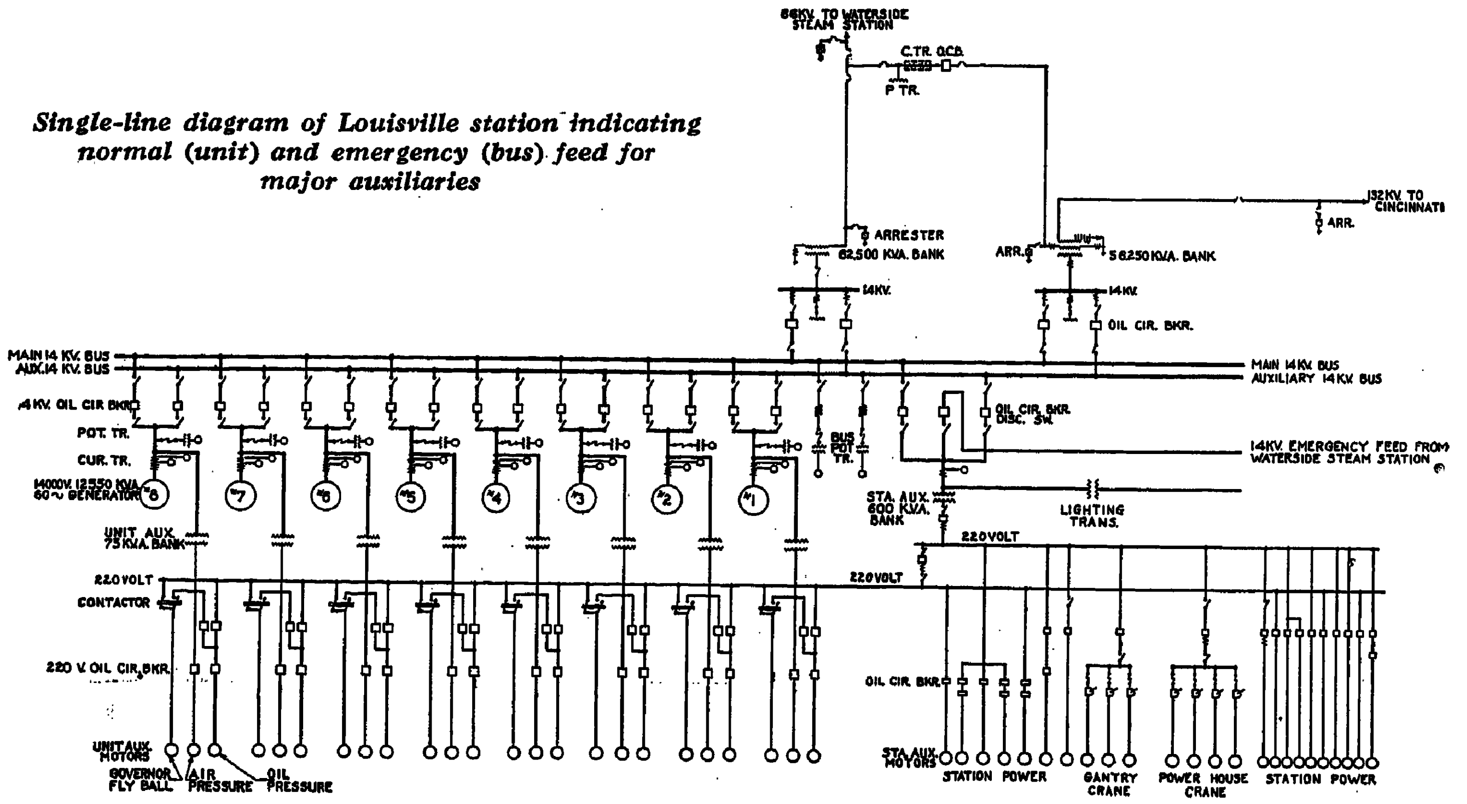
Three years of successful operation of the original plant, with successful installation and operation of later important additions, have demonstrated conclusively the entire justification of the departure from conventional layouts. It has been proved that the miniature switchboard accomplishes in a successful manner the centralized control and supervision of equipments widely separated physically. This has been done with minimum space and cost and in such a way that future requirements may be met in an economical manner as they develop and with no capital outlay in advance of the actual operating requirements.

Water supply for the Louisville plant comes through the Ohio River from a 91,000-sq. mi. area extending well into New York, Pennsylvania, Virginia, and Maryland. Conditions are such that the natural flow of the river varies from about 792,000 sec.-ft. at the time of maximum flood to 5,000 sec.-ft. or less during summer drought; whereas the present total water capacity of the plant is 32,000 sec.-ft. The 8,680-ft. dam, which was built in connection with the U. S. government's Ohio River canalization plan, is the longest and highest dam on the Ohio River. Together with the natural fall of some 28 ft. in the river bed at Louisville, a maximum operating head of 37 ft. is provided.

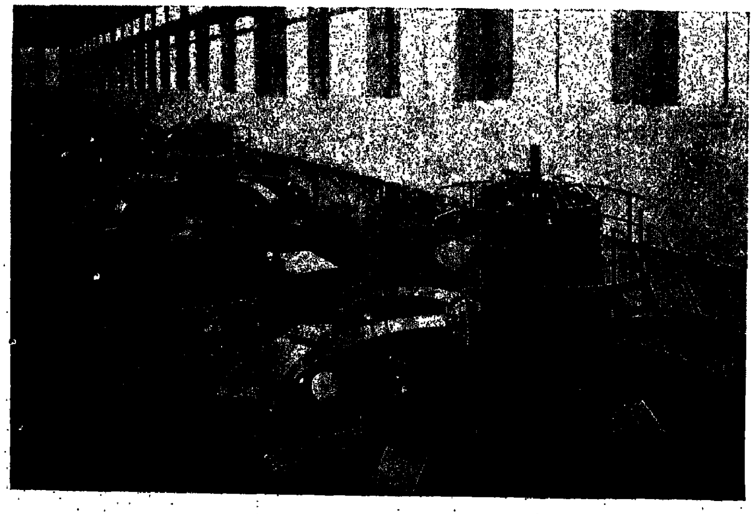
The water-level variation had much to do with the design of the station; to save in superstructure, the generator room floor is depressed 16 ft. below the entrance level which is 4 ft. above maximum high water, and water-wheels are placed near the low-water level. At present eight 13,500-hp. units (at 37-ft. head), are installed and provision is made for two additional units. Because of their ability to operate under heads varying from the maximum of 37 ft. down to 8 ft. five-blade propeller-type, axial-flow runners, designed to produce 13,500 hp. at 37 ft. net effective head at a speed of 100 rev. per min., were selected.

The 15-ft., 20-ton, cast-steel runner is connected to the rotor of the generator by 61 ft. of 23-in. shaft, the 125-ton combined weight of the assembly being suspended from a spring-type thrust bearing. Because of the long shaft four guide bearings, three of babbitt and one of lignum vitae, are used. Electrically driven fly-ball governors operated automatically provide positive control to servo motors and guide-vane latches, the latter being mounted directly on the cover plate to eliminate strains on the shift ring.

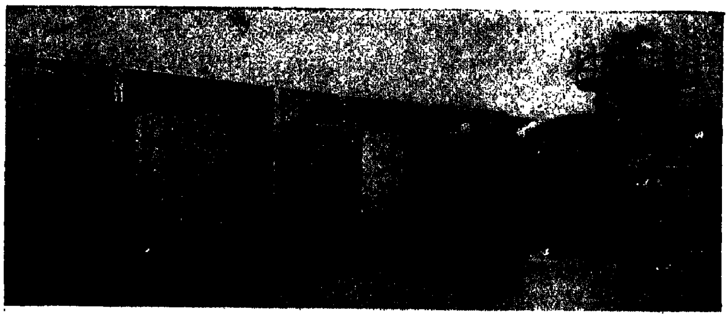
Single-line diagram of Louisville station indicating normal (unit) and emergency (bus) feed for major auxiliaries



Each generator is rated at 12,550 kv-a., 14 kv. at 100 rev. per min. and equipped with direct-connected exciters mounted on the thrust-bearing housing. From the armature winding twelve leads are brought out to a terminal board to permit differential protection, and also for the purpose of changing the operating characteristics as desired. Normally for full-load operation the windings are connected two-circuit Y but for light loads they may be connected one-circuit delta. Improved efficiency of the delta connection as compared with the Y connection is computed to vary from 2.1 per cent at 10 per cent of full load to 0.5 per cent at 75 per cent of full load, 0.9 power factor. Above 75 per cent of full load the Y connection is used and normal efficiencies are obtained. Generator ventilation and cooling is accomplished through a totally enclosed system and all leakage air is made up through air filters to remove dust and dirt. The continuing clean condition of armature and field coils resulting from this ventilation system has kept the efficiency of the units at the original value.

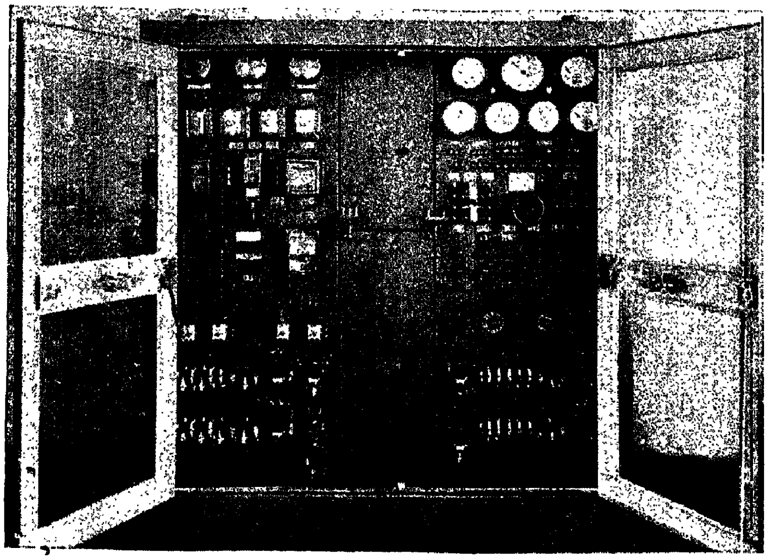


Generator room of the Louisville plant showing the present eight 12,550-kv-a. generating units, each with its immediately associated switching and control equipment. Buses run the length of the power house in the sheet-steel enclosure along the upstream wall, back of the generators



One of the unit groups; (from the right) generator, hydraulic governor, supervised control and regulating cubicle, and two oil circuit breakers

Manual and automatic control of the generators, outgoing lines, and station service banks is performed by means of standard panels and control equipment located in close proximity to the equipment controlled. For

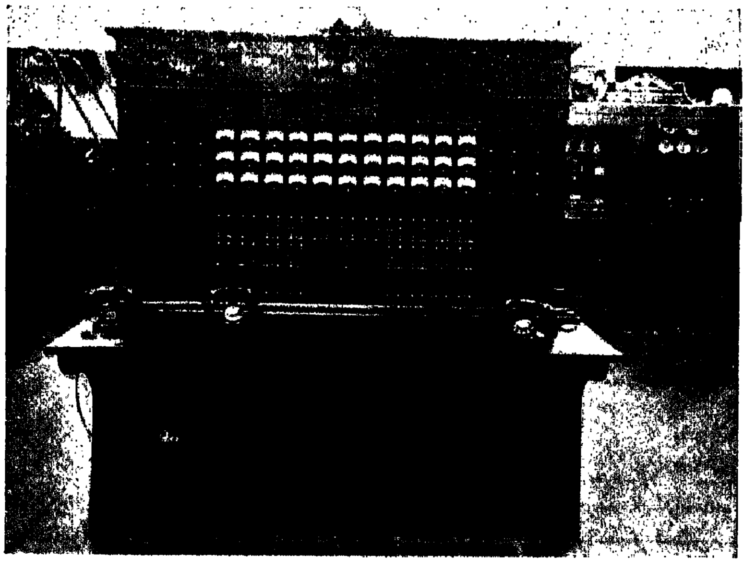


Interior (front) of a generator cubicle which contains instruments for both manual and automatic control of its generating unit. Pull-button switches on doors and floor-attendant signal lights on top of cabinet may be noted also

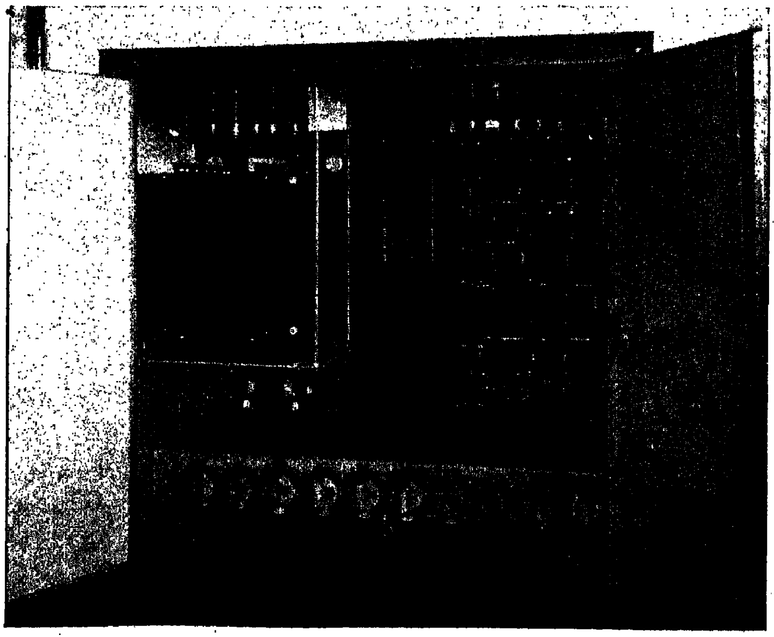
protection of th control equipment these switchboards with associated relays, contactors, etc., are mounted in sheet steel housings. Both control and meter circuits are brought to the switchboards by means of Greenfield cable through multi-circuit train-type couplers. These couplers facilitate maintenance and greatly expedite quick and complete isolation of the board.

Each hydroelectric generating unit is designed as a complete station within itself with its individual auxiliaries automatically and independently operated. Realizing that auxiliary failures mean jeopardized service, several additional features were included to insure dependable operation. The scheme of unit auxiliary equipment also is carried out as regards electrical equipment, in that all of the auxiliaries with the exception of compressed air for the brakes and the d-c. control voltage are fed directly from each generating unit.

During the starting period, the governor fly-ball and oil-pressure-pump motors are fed from a 230-volt station auxiliary bus. As the generator comes up to speed and 85 per cent of normal voltage is reached the governor fly-ball motor is transferred automatically to the unit feed. The governor oil-pressure motor is transferred manually from the station feed to the unit feed. The generator cooling-water pump motor is fed directly from the unit transformer bank at all times; as previously mentioned, excitation for the generator is from direct-connected exciters.



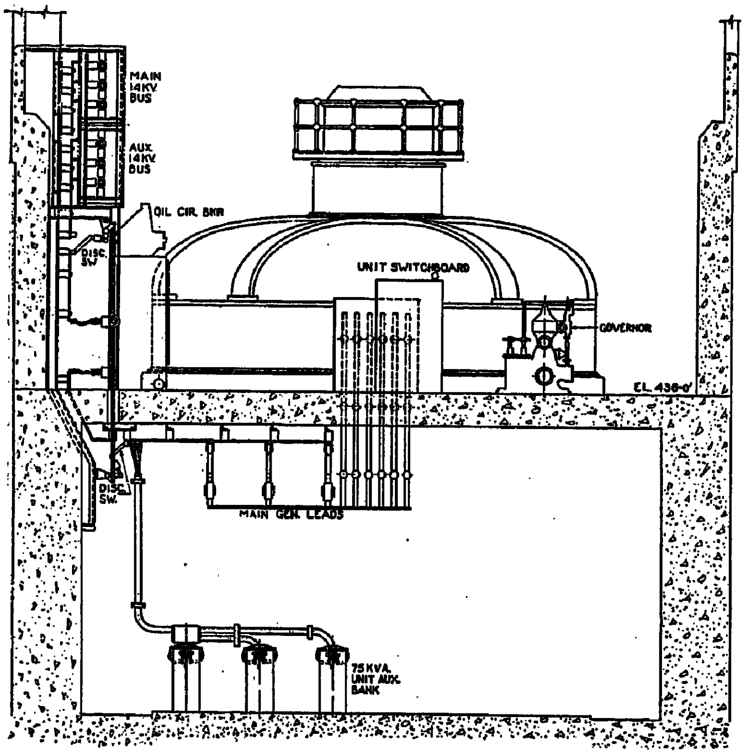
Central supervisory board with its four-inch panels



Rear of generator cubicle; train-type multi-circuit couplers expedite maintenanc

The miniature switchboard used to provide centralized control of the operations of the station is centrally located on the generator floor between units Nos. 4 and 5. The control equipment consists of a two-position control key for each circuit breaker or other device controlled, together with the usual red, green, and white signal lamps. In addition to the supervisory control keys the miniature board contains voltmeters, reactive volt-ampere meters, wattmeters, switches for raising and lowering load, and switches for regulating voltage. Control and meter circuits are taken from the supervisory panels by means of low-voltage telephone wires to a terminal box beneath the generator room floor. From that terminal box to an auxiliary terminal box near the unit switchboards lead-covered 16-pair telephone cable in rigid conduit is used, there being one such cable between the supervisory panels and each generator, transformer bank, and station auxiliary switchboard unit. Insulating, potential, and current transformers protect the small instruments on the supervisory board.

In the operation of the control equipment the operator at the supervisory panel selects by turning his bus selector key the bus to which the machine is to be synchronized giving the starting signal to the floor attendant by turning the "start and stop" control key to the "start" position; he also selects whether automatic or self-synchronizing is to be used in each particular instance. The floor attendant then checks to see that the gate limit stop is set for full-speed no-load value of head, and closes a pull-button control switch on the door of the generator cubicle to give the actual starting impulse to the unit. The usual assembly of protective and interlock devices prevents improper sequence in the operation and serves to shut down all related equipment when something goes wrong.

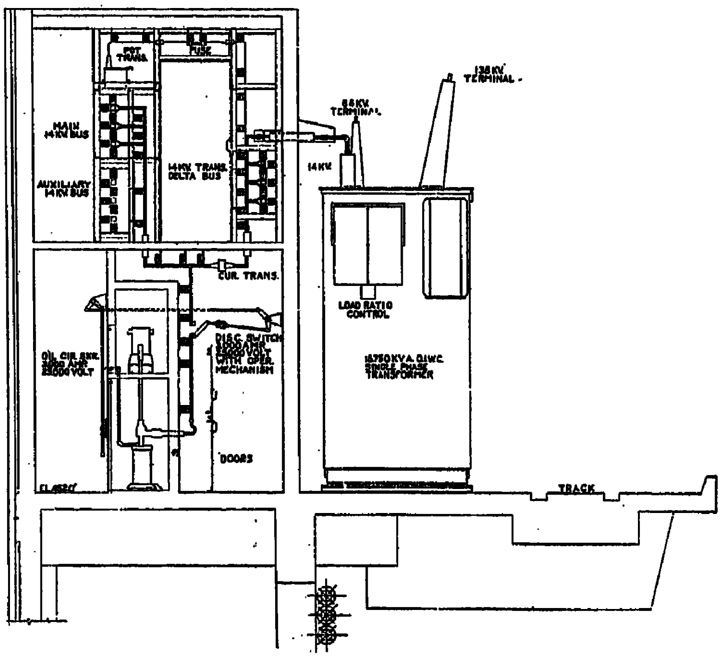


Generator leads are simplified with the unit grouping; main and auxiliary buses extend the length of the station

Operation of the Ohio Falls station depends entirely upon the flow of the river. Low water and small volume or the rapid and excessive rise of tailwater under flood conditions because of restrictions in the channel downstream, result in a curtailment of power output. The average yearly complete shutdown due to high water is 45 days. To meet navigation requirements the forebay pool is maintained as nearly constant as possible at El. 420, thus necessitating plant operation at the highest point of efficiency during low-water periods, at which time the plant operation is the governing factor of the pool stage. To meet emergencies for short periods all available equipment can be put into service within two minutes. Of course during periods when the flow exceeds the discharge capacity of the station, efficiencies are disregarded, and pool stages are controlled by a combination of manipulation of dams and plant operation.

Appreciable savings both in time and in labor costs in operating this plant have been realized as a result of the use of automatic control equipment. Only one switchboard operator is required on a shift, and where five floor men per shift would have been required for the eight generating units under other conditions, in this station only three are required.

Maintenance costs on the station have been even lower than were at first expected, which has given rise to the belief that the use of automatic equipment has resulted in less rather than in more maintenance. Experience shows that with the equipment once properly adjusted, the routine tests and inspection have been the smallest maintenance item. These tests are conducted weekly and require only the part time of one maintenance electrician.



Main transformer connections also are simplified

The miniature switchboard is expected to permit further economies and may even be removed to a future nearby steam station in which case one operator can control both stations.

Magnetic Circuit Units Adopted by I. E. C.

Standardized designations already adopted will obviate confusion if generally ratified; further international standardization of electromagnetic nomenclature is urged.

By Arthur E. Kennelly

Professor Emeritus of Electrical Engineering
Harvard University, Cambridge, Mass.
Fellow A. I. E. E.

AT a plenary meeting of the International Electrotechnical Commission (I. E. C.) held in Scandinavia in the summer of 1930 was conducted a series of international committee meetings on the subject of electric and magnetic units. Agenda for that series of meetings had been prepared and distributed internationally many months in advance. In America a subcommittee on magnetic units of the U. S. national committee of the I. E. C. had held a number of meetings in New York, had prepared duly approved agenda for Scandinavia, and had distributed the same among the other national committees abroad.

Ever since the electrical congress at Paris adopted the C. G. S. magnetic units *maxwell* and *gauss* in 1900, there has been a growing confusion in international electrotechnical literature as to the proper use of the unit *gauss*. Some writers used the *gauss* as the unit for magnetizing force $\mathcal{H}$, others used it for magnetic flux density $\mathcal{B}$, and still others used the *gauss* for both $\mathcal{H}$ and $\mathcal{B}$ indiscriminately. This vagueness and lack of uniformity was not confined to the literature of any single country; it was found in that of all or nearly all countries and the confusion may be said to have become universal. There was, however, universal agreement upon the internationally accepted equation

$$\mathcal{B} = \mu \mathcal{H} \qquad (1)$$

where $\mathcal{B}$ is the flux density in a magnetizable medium, $\mathcal{H}$ the magnetizing force, and μ the permeability of the medium. In the case of a vacuum, or free space—*i. e.*, non-magnetic material—the same equation becomes

$$\mathcal{B} = \mu_0 \mathcal{H} \quad \text{gausses} \qquad (2)$$

where μ_0 is the permeability of free space, which admittedly is equal numerically to unity in the C. G. S. magnetic system.

In equation (2), if space permeability μ_0 is a mere number unity, then both $\mathcal{B}$ and $\mathcal{H}$ are expressible in *gausses*; but if μ_0 has physical dimensions and is not a mere unit number, then $\mathcal{B}$ is expressible in *gausses* but $\mathcal{H}$ is different, and is expressible in some other unit.

The I. E. C. Scandinavian meeting decided unanimously in favor of the electrotechnical convention that μ and μ_0 are physical quantities and not mere numerics, and that $\mathcal{B}$ only should be expressed in *gausses*. For the expression of $\mathcal{H}$, a new unit name was adopted; namely, the *oersted*. In fact, Oersted was the Danish physicist who discovered at Copenhagen in 1820 the experimental fact, previously unsuspected, that a wire carrying an electric current exercises a deflecting magneto-mechanical torque or couple upon the poles of a suspended magnetic needle.

After reviewing the I. E. C. decisions on magnetic units as made at Oslo, recommendations for future consideration and discussion are made as follows:

(1) The I. E. C. decisions at Oslo to be ratified and generally adopted, thus eliminating confusion among magnetic units in the future.

(2) Another C. G. S. magnetic unit for reluctance might advantageously be adopted in the future. In America the *oersted* was used very generally as the unit of magnetic reluctance, but this had never been adopted internationally and the assignment of the *oersted* to magnetizing force $\mathcal{H}$ leaves a gap in the series of units expressing magnetic Ohm's law.

(3) A series of magnetic units in the practical or *volt-ampere-ohm* system might advantageously be considered in the future, commencing with the *pramaxwell* adopted at Oslo; but that before attempting any further international action on practical magnetic units, certain preliminary questions as to rationalization and also the particular system to be adopted, should first be studied, formulated, and internationally settled. This necessarily will take time.

From "Magnetic-Circuit Units as Adopted by the International Electrotechnical Commission" (No. 31-7) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

Electric Welding Advances in Modern Building Construction

CONSIDERING the new field arc-welded fourteen-story office building of the Edison Electric Illuminating Company (Boston) and a nineteen-story all-welded structure in Dallas, Texas, a few of the data on the Boston job as given by Frank P. McKibben in the *G. E. Review* (Dec. 1930) may be of something more than passing interest.

A combination of shop riveting and field welding effected the best use of facilities available. Steel erection was begun April 9, 1930, followed by the welding beginning on April 28, completion of erection June 26, and completion of welding June 27. Four welding machines were used and seven welders chosen by competitive tests of their work. Of a total of 1,314 tons of structural steel in the structure, 1,050 tons were electrically welded with 2,080 lb. (net) of electrode in 1,205½ man-hours of labor and 6,120 kw-hr. of electric energy. Filet per ton of steel welded amounted to 57.63 in. with 50.2 in. deposited per welding man-hour. Filet deposited per eight-hour day amounted to 402 in.; per pound of wire melted, 29.09 in.; and per kw-hr., 9.9 in. Electric energy required per ton of building steel amounted to 4.66 kw-hr.; per ton of welded steel, 5.83 kw-hr.

Inspection service included, (1) qualification and periodic tests of welders, (2) ascertaining the use of proper electrodes and current values, and (3) in verifying completed welds as to quality and as to size, length, and location in accordance with plans. A complete daily log was kept.

The Oil-Blast Circuit Breaker

A further development of the explosion-chamber principle avoids the mixing of arc and oil in the main gap, utilizing the high oil pressure together with smooth and controlled flow of oil from the chamber to sweep away the arc, replacing it with a stream of clean oil. With this design tests show that a voltage of 44 kv. per inch across the working gap actually is reached.

By D. C. Prince *and* *W. F. Skeats*
Fellow A. I. E. E. Associate A. I. E. E.
Both of the General Electric Company, Schenectady

FOR MORE than thirty-five years the oil circuit breaker has been used as an interrupter for a-c. circuits and it still is the most practical, economical, and effective device so far developed for that purpose. In recent years much study has been given to the determination of the fundamental characteristics of the arc in oil as encountered in oil circuit breakers. One of the first important facts brought to light by these studies was that an unconfined arc in oil is extremely erratic in length, duration, and amount of gas formed. Even the maximum arc lengths vary in different sizes of breakers at the same currents and voltages, and in the same breaker are different with various opening speeds. These maximum values for various conditions and voltages have been determined from actual tests and are used as the design basis in plain-break breakers.

An excellent analysis of oil circuit breaker phenomena explaining the qualitative factors governing deionization rates in arcs, is to be found in the A. I. E. E. TRANSACTIONS, Vol. 49, 1930, pp. 421-446 ("Extinction of a Long A-C. Arc," by J. Slepian, and "The Use of Oil in Arc Rupture," by B. P. Baker and H. M. Wilcox.) The principle of confining the arc and maintaining a supply of oil in its immediate vicinity has been confirmed, although the means suggested differ considerably in operation from the method employed in the explosion chamber. The importance of low dissipation of energy in the arc in keeping down the mechanical stresses accompanying an interruption has been set forth, and a new structure has been developed for the purpose of accelerating the deionization of a mixed gas-and-oil arc path, so as to raise its dielectric strength during the short interval while the restoration of voltage across the breaker contacts is taking place. The deionization processes suggested, however, operate vigorously throughout the current cycle, requiring for an arc of given length, high voltage and energy dissipation and causing, therefore, a rapid evolution of gas. This is unavoidable where effective deionization at the current zero must be secured in a fairly homogeneous arc path. But the arc path at the time of rupture need not be homogeneous and it is the purpose of this paper to describe a process operating along entirely different lines.

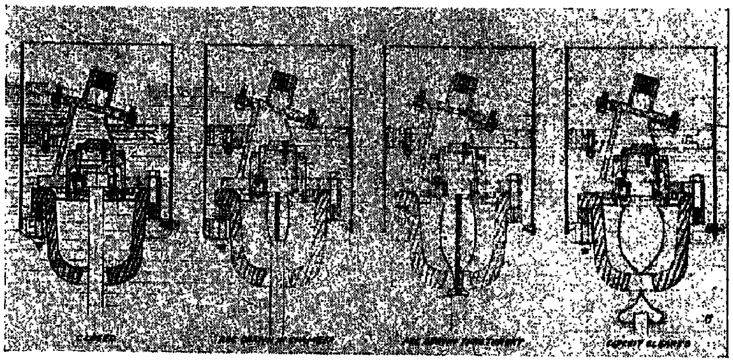

Fig. 1. Four successive stages in the operation of an ordinary explosion chamber

For existing circuit breakers the arc path at the time of rupture has an effective dielectric strength of from about 2.5 kv. per in. in plain-break circuit breakers up to 10.0 kv. for the deion-grid breaker, and as high as 15.0 kv. for standard explosion-chamber circuit breakers. Clean oil has a dielectric strength of over

---

From "The Oil-Blast Circuit Breaker" (No. 31-5) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

200.0 kv. per in., with a strength under impulse over 600.0 kv. per in. The introduction of any considerable amount of solid oil into the gap at the current zero therefore holds possibilities of great improvement over other methods of interruption.

Under the worst conditions line voltage may be impressed across a 15-kv. breaker in 10 microseconds. The rate of voltage rise is then $\sqrt{2} \times 1.5 \times 10^9$ volts per sec. Assuming the oil to have the dielectric strength it presents to impulse voltages, or about $\sqrt{2} \times 6 \times 10^9$ volts per in., fresh dielectric must be introduced at the rate of 200 ft. per sec. This velocity corresponds to a pressure of 255 lb. per sq. in., which is not an unusual explosion-chamber pressure.

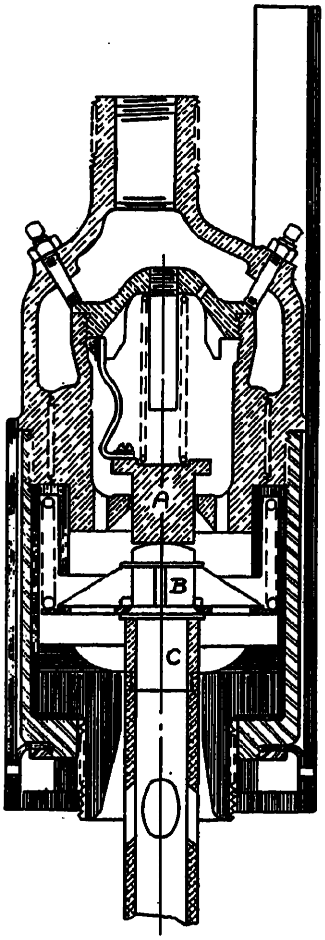

Fig. 2. Explosion chamber specially designed to utilize more effectively the kinetic energy of escaping oil to cut the arc

A high-voltage transformer will have a recovery rate corresponding to $\sqrt{2} \times 5 \times 10^9$ volts per sec. while the rate for a long-distance 220-kv. transmission line will be about $\sqrt{2} \times 0.8 \times 10^9$ volts per sec. even though the full voltage corresponds to 220 kv., line-to-line. It is quite possible to design a circuit breaker so that oil will sweep away the arc at the rate required by the foregoing calculations.

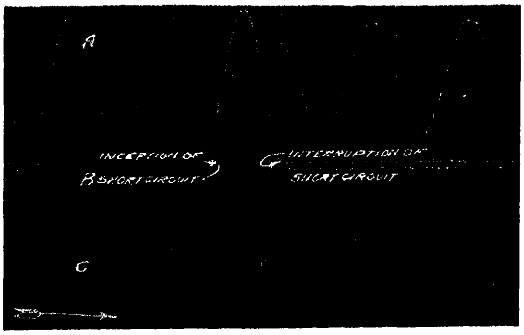

Fig. 3. Oscillogram of interruption of 24,800 amperes at 13.2 kv., 24 cycles, by an oil-blast breaker; (A) voltage across contacts; (B) line current; (C) tank pressure

Effectiveness of the explosion-chamber breaker may be explained in this way. Fig. 1 shows a standard high-speed explosion-chamber circuit breaker in four positions. In the first diagram the breaker is shown in the closed position; in the second, the contacts have separated and a small arc has been drawn which has decomposed sufficient oil to place the remaining oil in the explosion chamber under considerable pressure; in the third diagram, the moving contacts have reached the explosion-chamber throat and oil is being crowded in upon the arc in the throat; in the fourth diagram the

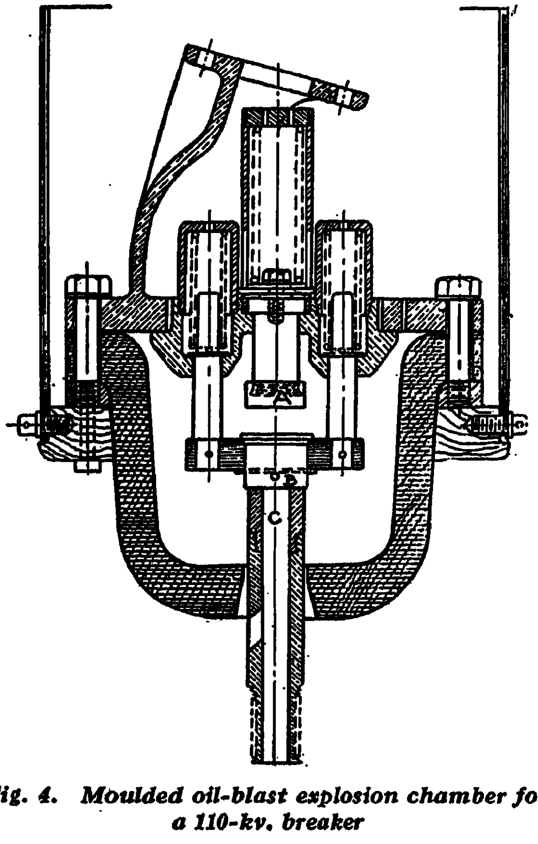

Fig. 4. Moulded oil-blast explosion chamber for a 110-kv. breaker

oil has divided the gas bubble into two parts, interposing a solid wall between them, and thus effectively opening the circuit.

As the gas bubble expands, driving the oil through the throat of the explosion chamber, the pressure varies from hundreds of pounds in the large part of the volume of the explosion chamber to a very low value actually in the throat; that is, the potential energy of pressure has been converted into kinetic energy of velocity. At the same time, since the pressure is low in the throat, the oil can very easily rush into this space so as to cut the arc in two.

TABLE I—TESTS OF 110 KV., 600 AMPERE OIL-BLAST CIRCUIT BREAKER

Feb. 6, 7 & 18, 1930

Voltage	Amperes	Arc duration Cycles	In. per break	Kv. per in.
22 kv.	1530–1880	0.8–2.2	0.8–2.6	4.2–13.7
44 "	3240–5000	0.5–1.5	0.5–1.7	13–44

To make this action even more positive the form of explosion chamber shown in Fig. 2 has been developed. It contains an upper butt contact *A*, a floating contact *B*, and a hollow contact *C*. When the breaker is tripped, the floating and hollow contacts, *B* and *C*, start down, driven by the opening springs, thus drawing a short arc between *A* and *B*. This arc forms gas and places the oil in the explosion chamber under pressure for which there is little relief until the floating contact reaches its stop. The secondary break and arc then occurs between contacts *B* and *C*; however, as the oil glides through the passageway in the contact rod, this arc is carried before it and exists alongside of it without mixing—hence with a minimum loss throughout the current cycle. Then, as soon as the current zero is reached, the arc products are displaced by a smoothly flowing wall of solid oil, the dielectric strength of which has not been impaired by carbonization or entrained ionized gas.

Several beneficial effects are obtained by the use of this modification: In the first place, the necessary arc length at generator voltages is reduced from something slightly in excess of the inside length of the explosion chamber to a little more than one inch per break. With a given contact speed this shorter arc can be established more rapidly—of decided advantage in cutting down the duration of short circuit and the arc-energy dissipation. The importance of reducing the energy from the points of view of (1) keeping down the mechanical stresses and oil deterioration resulting from a given interruption, (2) increasing the interrupting capacity of a structure of given size, and (3) minimizing the demonstration accompanying an interruption—has been previously established. In addition, the shorter arc duration results in less burning and longer life of the contact parts and of the oil. Also, both arcs are quite effectively kept away from insulating material so that burning of insulating parts is reduced. These two latter effects operate to cut down inspection and replacement requirements. Finally, the oil is more effectively directed into the second gap, so that the current range over which the chamber operates effectively is increased.

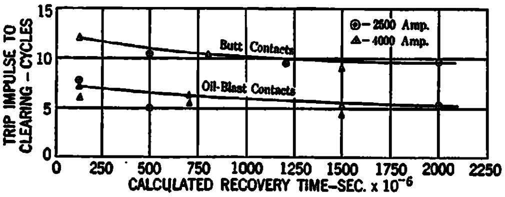

Fig. 5. Results of service tests of a 600-ampere 132-kv. oil-blast breaker

More than 250 tests have been made with currents from 900 to 25,600 amperes at 13.2 kv. and up to 56,400 amperes at lower voltages. Above 5,000 amperes the arc is uniformly extinguished at the first current zero occurring after the secondary contacts have been separated by as much as an inch; and in many cases the arc has been extinguished with a contact separation of but a quarter of an inch. Fig. 3 is a typical oscillogram showing the operation of this circuit breaker.

The need for high speed of interruption is fully as urgent at transmission voltages as at generator voltages. Accordingly, a somewhat larger explosion chamber was modified to correspond to Fig. 2. This arrangement was found to be effective up to 44 kv., as is demonstrated by the data in Table I. By comparison with the performance of the standard explosion-chamber breaker, the data shown in this table indicate consider-

TABLE II—TESTS OF 110-KV. 600-AMPERE OIL-BLAST CIRCUIT BREAKER

March 18 & 19, 1930

Kv.	Amperes	Arc duration Cycles	In. per break	Arc energy	Kv-a. x 1,000	Watts-secs. Kv-a.	Kv. per In. in arc
66	2,020–2,940	1.75–3.00	5.25– 7.50	23–35	171–194	0.118–0.187	4.4– 6.3
88	1,890–2,210	2.25–3.75	5.25–11.00	14–58	166–194	0.084–0.350	4.0– 8.4
110	1,540–1,740	2.25–3.75	5.25– 9.00	11–36	169–191	0.059–0.199	6.1–10.5
132	790–1,570	2.25–6.00	4.50–21.90	18–65	104–207	0.087–0.458	3.0–14.7

Contact burning negligible. No-load speed 7.8 ft. per sec.
Oil deterioration negligible.
No measurable pressure above oil.

able improvement. Whereas with the standard explosion chamber, arc lengths vary from four to eight inches, those in Table I vary from 0.5 to 2.5 in.

At 110 kv., however, it was found more desirable to substitute molded explosion chambers for the steel chambers used at the lower voltages. Detailed arrangement of these chambers is given in Fig. 4. Oscillograms show that with this combination the arc duration is about three cycles, and both arc drop and arc energy are very low. Results of many tests are shown in Table II.

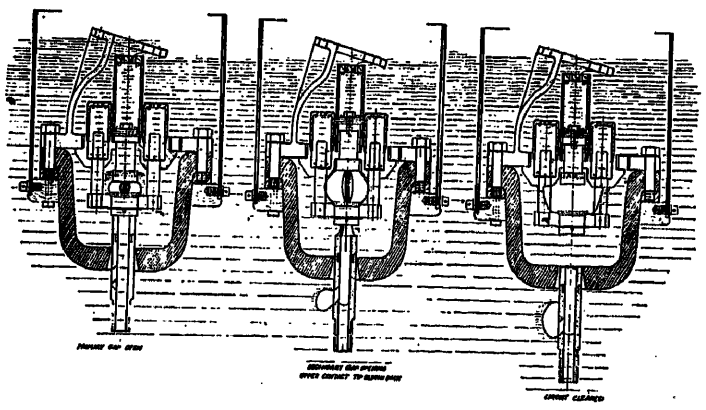
A



B C D

Fig. 6. Distribution of arcs and gas in four steps of operation of an oil-blast breaker

A 132-kv., 600-ampere breaker with the explosion-chamber arrangement just described was installed and tested under short-circuit conditions at the Philo plant of the American Gas and Electric Company. Its actual over-all interrupting time as compared with an ordinary butt-contact explosion-chamber breaker is revealed in Fig. 5. Field data gathered in these tests are presented and discussed in a paper prepared and presented by R. M. Spurck and H. E. Strang, at the winter convention in New York Jan. 26-30, 1931. The gain in the case of the oil-blast contacts is more impressive when it is remembered that in both cases the mechanical time required to separate the contacts is the same.

During the tests it was found that in many cases the circuit has been successfully opened with chamber pressures less than those previously calculated as theoretically necessary. This is explained by a more complete analysis of the oil flow during the arcing period.

Fig. 6 shows a series of drawings representing the locations of arcs, gas, and contacts during an operation of the breaker; Fig. 6A, the contacts in the closed position and in Fig. 6B the upper contacts have parted, establishing the pressure-generating arc. In Fig. 6C the lower contacts have parted and the current is still considerable, giving a fat arc. It is, however, beginning to be carried down the contact tube—which has been freed of oil—and gas is commencing to escape from the vent holes. As the arc dwindles with the cyclic decay in current, the oil moves radially inward along an area many times larger than the bore of the contact tube. At the current zero (Fig. 6D) the velocity of gas moving downward into the tube becomes many times the velocity of the inward-flowing oil. In effect the rate at which solid oil dielectric replaces ionized gas is the velocity with which the gas can go through the bore of the contact rod. The gas may pass through the contact tube at the velocity of sound, 2300 ft. per sec. in oil circuit breaker gas at ordinary temperatures, while at arc temperatures it probably exceeds 10,000 ft. per sec., which accounts for the extraordinary rate at which the space once occupied by the arc recovers its dielectric strength.

The principle of employing oil only instead of mixed oil and gas as the interrupting medium in oil circuit breakers is not limited to the larger types; smaller types applying this principle are under development and tests already made indicate that large decreases in arc length and increases in interrupting capacity will be obtained in all cases.

As relatively newcomers in the oil circuit breaker field, the authors would have been utterly unable to obtain the results which have been yielded by this investigation without the fine cooperation of the General Electric Company. Specifically Messrs. W. K. Rankin and W. E. Paul have contributed many of the ideas on which this paper is based, while G. F. Davis and his testing staff has made possible important checks upon theory, as well as the determination of the performance characteristics of the final designs.

Pittsburgh, host city to the Institute in March, offers many features of interest

Middle Eastern District
Offers Promising Program for Pittsburgh Meeting

IN high technical values as well as in the diversive attractions offered by a membership gathering, the March meeting of the Institute's Middle Eastern District No. 2 will offer material which none can well afford to miss. The William Penn Hotel, Pittsburgh, Pa., will be headquarters, and the many additional possibilities afforded by the Pittsburgh area will be made available to our guests by the plans which the local committees are formulating. The city itself, possessed of rare scenic beauty, has elevations offering an unusual panoramic view of the junction of the Allegheny and Monongahela rivers where they unite to form the Ohio River; its geographic location is such as to make it a major center of distribution; its endowment of natural resources in the surrounding hills, too, make for a great manufacturing center—the "Steel and Electric City." As far as the eye can scan, span after span bridge the rivers, with traffic—train, boat, vehicular and pedestrian—unceasingly present; while the auxiliary municipalities with which the river banks are lined make the constantly stirring action of the area doubly interesting to the mind of the energetic engineer.

The technical program will include papers on such all-important subjects as the interconnections between utilities and industry, a description of the new primary network now being installed in Pittsburgh, a symposium on the latest methods of grounding, relaying and fault-correcting for transmission systems (including another paper by Miss Edith Clarke), the miscellaneous applications of power to industry, and a live discussion of today's communication problems.

Briefly stated, the program is as follows:

Outline of Program

Wednesday, March 11, 1931

9:00 a. m.	Registration
10:00 a. m.	Address of Welcome—President William S. Lee
10:15 a. m.	Technical Session No. 1
2:00 p. m.	Technical Session No. 2
8:15 p. m.	Theater Party

Thursday, March 12, 1931

9:30 a. m.	Technical Session No. 3
12:30 p. m.	Luncheon for Student Branch Counselors and Chairmen
2:00 p. m.	Student Session
2:00 p. m.	Inspection Trips
6:45 p. m.	Banquet and Dance

Friday, March 13, 1931

9:30 a. m.	Technical Session No. 4
12:30 p. m.	Luncheon for Student Branch Counselors
2:00 p. m.	Technical Session No. 5

Entertainment

On Wednesday evening tickets for any of the Pittsburgh theaters may be obtained at the registration desk.

Thursday evening's social events will be the banquet and dance held in the main ballroom of the William Penn Hotel. An excellent program of music has been prepared by Pittsburgh's leading orchestra; favors for the ladies, and other special features will enhance the pleasure of the occasion. Reservations may be made in advance for tables seating ten persons; the tickets will be $4.00 each.

Ladies' Program

For the ladies' entertainment the Ladies Committee has arranged a sightseeing trip and tea on Wednesday afternoon, a luncheon and bridge on Thursday afternoon, and an indoor golf tournament and luncheon Friday morning.

Inspection Trips

The following inspection trips, which will afford an opportunity to see many recent developments of interest to the electrical engineering profession, have been planned for Thursday afternoon, March 12th:

1. The new KDKA broadcasting station at Saxonburg, Pa.
2. The East Pittsburgh Works of the Westinghouse Electric & Manufacturing Company, including the new Central and High-Power Laboratory.
3. The Homestead Works of the Carnegie Steel Company.
4. The Springdale Power Station and Coal Mine of the West Penn Power Company.
5. The James H. Reed Power Station of the Duquesne Light Company.
6. The new 4000 volt primary network of the Duquesne Light Company.
7. The low-tension alternating-current network of the Duquesne Light Company.
8. The Bell Telephone Building, Pittsburgh.

A description of each of these trips with details of transportation, time, etc., will be announced in the program distributed prior to, and during the meeting.

In addition to the above, special inspection trips will also be arranged upon request; *i e.*, to the Lake Lynn Hydro Station of the West Penn Power Company, or to other points of interest in the Pittsburgh district.

Railroad Information

Train reservations may be made at the hotels; further train information will be available at the meeting's information desk. There will be no special railroad rates.

Registration

Each member should register in advance by mail, thus permitting the early preparation of badges and the saving of considerable time and confusion at the registration desk.

Full information regarding the entire program will be mailed in advance to each member in the district; also a registration card, which should be returned promptly.

Committees

The personnel of the General Meeting Committee consists of the following: E. C. Stone, Vice-President, Middle Eastern District, No. 2; J. A. Cadwallader, Secretary, Middle Eastern District, No. 2; C. T. Sinclair, Chairman, General Committee; F. W. Braund, H. E. Dyche, F. C. Hanker, D. H. Kelly, H. C. Paiste and W. R. Work. Those who are making the local arrangements for the meeting are as follows: C. T. Sinclair, Chairman, General Committee; and the following who are chairmen of sub-committees: A. G. Butler, Inspection Trips; J. A. Cadwallader, Finance; Miss Karen Fladoes, Ladies Entertainment; F. C. Hanker, Meetings and Papers; Moreland King, Student Activities; R. L. Kirk, Publicity; J. A. MacGregor, Hotel Registration and Train Transportation; and W. B. Spellmire, Entertainment.

Hotel Reservations

Reservations for hotel accommodations should be made by writing directly to any one of the following hotels; William Penn, Fort Pitt, Pittsburgher, or Roosevelt. All of these are within easy walking distance of headquarters.

By special arrangement delegates may enjoy the privileges of the Keystone Athletic Club by making reservations through J. A. MacGregor, Bell Telephone Company, 19th floor, 416 Seventh Avenue.

The Engineers' Society of Western Pennsylvania, located in the basement of the William Penn Hotel, also have kindly offered the facilities of their club rooms to visiting engineers at the District meeting. These facilities include a very large and comfortable club room well furnished with magazines, card tables, and miscellaneous equipment. Delegates are urged to make full use of the facilities, which will be found a very great added convenience and pleasure during their stay.

In the matter of special hotel rooms desired for committee meetings, reservations should be made through Mr. MacGregor at the address given above.

Further information regarding hotel accommodations and rates will be included in the announcement to be mailed later.

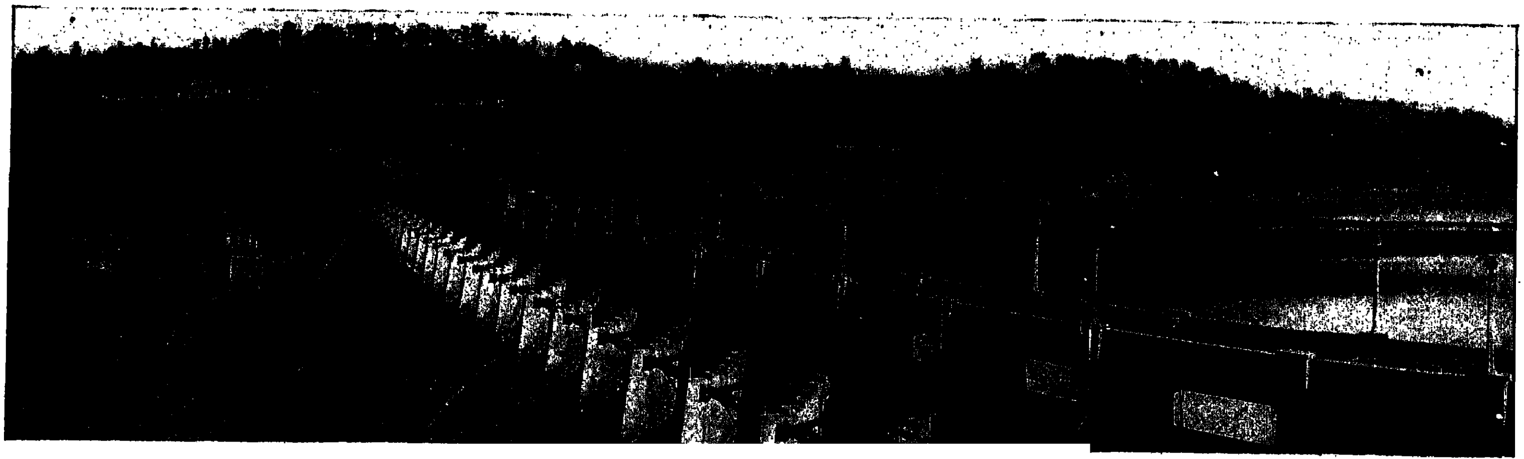
Technical Program

Wednesday, March 11—10:00 a.m.

Opening of Meeting

E. C. Stone, Vice-President, Middl Eastern District No. 2.

Address of Welcome, William S. Lee, President, American Institute of Electrical Engineers.



—Photo by L. F. Beaudry, Pgh.

Lake Lynn hydroelectric development of the West Penn Power Company

Session No. 1—On Cable Arcs and Arcs in Air

Sponsored by the Subcommittee on Distribution of the Power Transmission and Distribution Committee.

Burn-Off Characteristics of Low-Voltage Network Cables, G. Sutherland and D. S. MacCorkle, New York & Queens Electric Light & Power Company.

Arcs in Low-Voltage A-C. Network Cables, J. Slepian and A. P. Strom, Westinghouse Electric & Manufacturing Company.

The Re-ignition of Metallic A-C. Arcs in Air, S. S. Atwood, W. G. Dow, and W. Krousnick, University of Michigan.

Wedn sday, March 11—2:00 p. m.

Session No. 2—On Distribution Networks

Sponsored by the Subcommittee on Distribution of the Power Transmission and Distribution Committee.

Vertical Networks in Metropolitan Office Buildings, A. H. Kehoe, United Electric Light & Power Company, and Bassett Jones, Consulting Engineer.

The Primary Network, R. M. Stanley and C. T. Sinclair, Byllesby Engineering and Management Corporation.

Operating Experience with Philadelphia A-C. Network, H. S. Davis and W. R. Ross, Philadelphia Electric Company.

Prepared discussion—arrangements will be made for interested engineers to present prepared discussions on the problems involved in network distribution systems.

Thursday, March 12—9:30 a. m.

Session No. 3—On Grounding, Relaying and Transmission

Sponsored by the Protective Devices Committee.

Committee Report on Present Day Grounding Practises, C. A. Powel, Chairman.

Reactance of Transmission Lines with Ground Return, J. E. Clem, General Electric Company.

Fundamental Basis of Distance Relaying, W. A. Lewis, Westinghouse Electric & Manufacturing Company.

Power System Voltages and Currents Under Fault Conditions, R. D. Evans and S. H. Wright, Westinghouse Electric & Manufacturing Company.

Simultaneous Faults and Six-Phase Transmission, Edith Clarke, General Electric Company.

Thursday, March 12—2:00 p. m.

Student Session

Address, William S. Lee, President, American Institute of Electrical Engineers.

Summer Employment for Engineering Students, Wm. D. Bruce, University of Pennsylvania, and M. M. Boring, General Electric Company.

Qualifications Looked for in a Cadet Engineer, Lewis Fussell, Jr., Swarthmore, College, and Dr. E. B. Roberts, Westinghouse Electric and Manufacturing Company.

Has the Student Branch any Responsibilities to the Freshman and Sophomore? P. W. Seal, Lehigh University and G. A. Sanow, Case School of Applied Science.

A Review of Student Branch Activities in District No. 2, Professor J. T. Walther, University of Akron.

Friday, March 13—9:30 a. m.

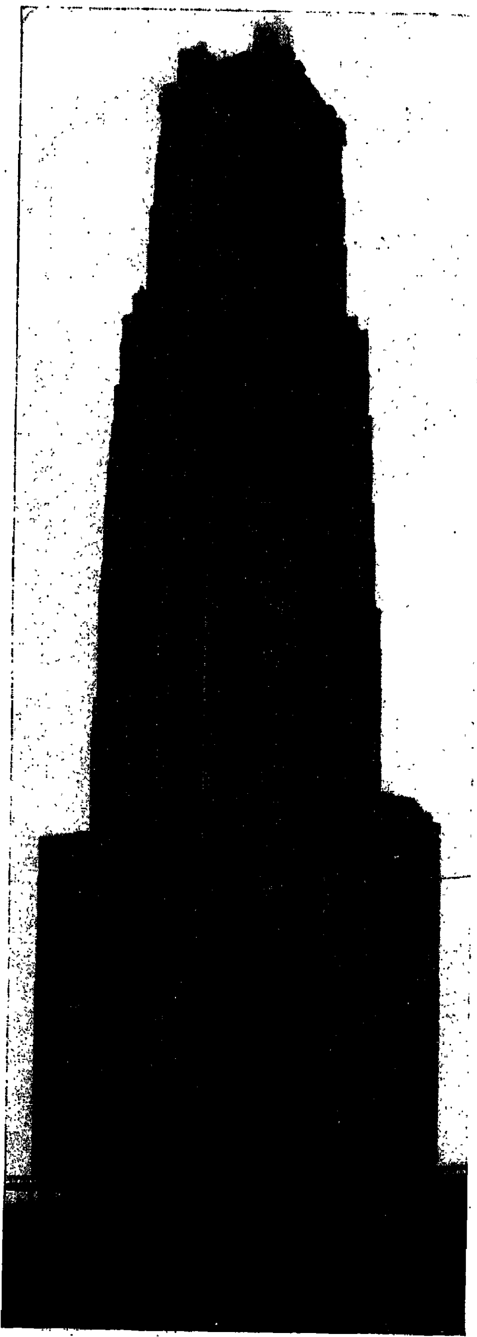
Session No. 4—Selected Subjects

Part I

Conversion and Distribution of General Purpose D-C. Power in Large Industrial Plants, R. D. Abbiss, Carnegie Steel Company, and D. C. West, Westinghouse Electric and Manufacturing Company.

Part II—Symposium on Interconnection between Utilities and Industries.

Interconnection Between the Duquesne Light Company and the Davison Coke & Iron Company, G. E. Dignan, Davison Coke & Iron Company, and R. L. Kirk, Duquesne Light Company.



A vertical campus; the University of Pittsburgh's Cathedral of Learning is nearing completion

Interconnection for Power Between Public Utilities and Large Industrial Users, F. O. Schnure, Bethlehem Steel Company.

Absorption of By-Product Power, A. Hoefle, Toledo Edison Company, and W. T. Woodmancy.

All the papers in this Session will be reprinted by the Association of Iron and Steel Electrical Engineers.

Friday, March 13—2:00 p. m.

Session No. 5—Selected Subjects

Part I—Industrial Power Applications

The Use of Electricity in Large Annealing Furnaces, J. C. Woodson, Westinghouse Electric & Manufacturing Company.

The Use of Electricity in a Modern Dairy Plant, H. C. Brunner, Westinghouse Electric & Manufacturing Company, and A. G. Droux, Rieck McJunkin Company.

Part II—Communications.

Description of KDKA Broadcasting Station, R. L. Davis, Westinghouse Electric & Manufacturing Company.

Power Supply for Telephone Systems, R. L. Young and R. L. Lunsford, American Telephone & Telegraph Company.

Power Supply for Telegraph Systems, E. W. Griffith.

Recent Developments in the Operation of Overseas Telephone Service, F. A. Cowan, American Telephone & Telegraph Company.

Pacific Coast Convention Plans Announced

Taking advantage of the natural beauties and other attractive features of California's famous Lake Tahoe, the San Francisco Section, hosts to the 1931 Coast convention of the Institute have decided to hold that gathering at the mile-high lake resort. Facilities for technical inspection trips are generous and recreational possibilities are claimed to be second to none. Transportation both by rail and automobile is convenient, and excellent provisions are available for the convenience of family groups; hence there is the invitation to "make it your family vacation trip."

Tentative dates set are August 25-29 inclusive, a time chosen to synchronize with school terms.

Committee Appointments

Convention committee chairman as announced include A. W. Copley, general chairman; P. B. Garrett, general vice-chairman; E. F. Maryatt, general secretary; A. G. Jones, entertainment; E. A. Crellin, finance and hotel; A. V. Thompson, Golf; F. R. George, inspection trips; W. C. Heston, publicity; M. S. Barnes, registration; C. E. Fleager, (Eighth District vice-president) reception; D. I. Cone, technical program; Prof. S. G. Palmer, student activities; Paul Lebenbaum, transportation.

Units and Definitions Adopted by International Electrotechnical Commission

INTERNATIONAL agreement on the definitions and names of additional magnetic units was reached by the International Electrotechnical Commission at its meeting in Oslo (Scandinavia) July 1930. This constitutes a further important advance in the standardization of electromagnetic units brought about through the efforts of this commission. The following is an unofficial summary of the actions taken:

The story begins with the preceding plenary I. E. C. meeting in 1927 at Bellagio, when a proposal was presented by the Italian National Committee, to adopt a unit of magnetic flux Φ, in the practical or volt-ampere-ohm system of units, with a certain definite name. For consideration and report the proposal was referred to a special subcommittee of advisory committee No. 1, on nomenclature to be known as the Subcommittee on Magnetic Units, and comprised of one representative from each of seven National Committees (France, Germany, Great Britain, Holland, Italy, U. S. A. and U. S. S. R.).

The members of this subcommittee exchanged much friendly correspondence upon the subject; but their views differed materially and no consensus of opinion could be reached. It was therefore decided to ventilate the question by papers and discussions in the various countries and I. E. C. national committees, with a view to paving the way for international agreement at the 1930 plenary Scandinavian meeting.

The I. E. C. Subcommittee on Magnetic Units agreed to attempt a revision of the C. G. S. units adopted at Paris in 1900, but in order to do so, it was first necessary to reach international agreement on the fundamental definitions of the C. G. S. magnetic units, and especially of magnetic permeability μ, on which question, differences of opinion have appeared in nearly all countries.

It is universally agreed that in a vacuum or in free space, with C. G. S. units, a uniform magnetising force $\mathcal{H}$ produces a uniform flux density $\mathcal{B}$ of the same numerical value; so that *space permeability* μ_0, or the ratio $\mathcal{B}/\mathcal{H}$, in free space, is unity. It has been much debated, however, whether, admitting that $\mathcal{H} = 20$ say, produces also $\mathcal{B} = 20$ in free space, the flux density $\mathcal{B}$ is identically the same physical quantity as $\mathcal{H}$; or whether the $\mathcal{H}$ sets up a quantity $\mathcal{B}$, which, although numerically the same, is physically different. If $\mathcal{H}$ and $\mathcal{B}$ are physically identical, it is not only superfluous but misleading to call them by different names and give them different units. The same unit *gauss* if applied to one would necessarily apply to the other. If, on the contrary, flux density $\mathcal{B}$ differs essentially from magnetising force $\mathcal{H}$; then it becomes necessary to have different units for these quantities, even if agreement cannot be reached as to the absolute dimensions of $\mathcal{B}$ and $\mathcal{H}$ in terms of length, mass, and time.

Decision at Stockholm on the Question of Permeability

At the first meeting of the Subcommittee on Magnetic Units, it was unanimously agreed to accept the hypothesis that for electrotechnical purposes, $\mathcal{B}$ and $\mathcal{H}$ in free space have different physical dimensions; so that their ratio μ_0 the space permeability, is a dimensional quantity and not the mere numeric unity (in the C. G. S. system).

It was also unanimously agreed that the ratio μ/μ_0 of the absolute permeability of a magnetic substance such as steel to the space permeability should be called its *relative permeability*, and should be taken as a pure numeric. Consequently when speaking of steel at a certain magnetising force as having an *absolute permeability* μ, of, say, 1,000, this is a dimensional quantity of the same dimensions as *space permeability* μ_0; but if we speak of its *relative permeability* μ/μ_0 as being 1,000, we refer to a mere numeric.

Formation of I. E. C. Subcommittee on Units and Magnitudes

The Subcommittee on Magnetic Units was enlarged in scope and membership by the I. E. C. committee No. 1 on nomenclature, with the new title, "Subcommittee on Electric and Magnetic Units and Magnitudes," and representatives of four additional national committees were appointed to it. The new subcommittee (E&M U&M) has one representative from each of the following national I. E. C. committees: France, Germany, Great Britain, Holland, Italy, Norway, Poland, Roumania, Spain, U. S. S. R. and U. S. A.

Names Adopted for C. G. S. Magnetic Units

The permeability question having been settled unanimously, the new subcommittee adopted either unanimously or by a large majority the following names for C. G. S. magnetic units:

For magnetomotive force (force magnetomotrice) . . . $\mathcal{F}$ the name *gilbert*
For magnetising force (champ magnetique) . . . . $\mathcal{H}$ the name *oersted*
For magnetic flux (flux magnetique) . . . . Φ the name *maxwell*
For magnetic flux density (induction) . . . . $\mathcal{B}$ the name *gauss*

It was urged on behalf of the Danish National Committee, that although the name oersted had been used in America for the C. G. S. unit of reluctance, yet this had never been adopted internationally; moreover, that Oersted had not interested himself in reluctance; but had actually discovered the magnetic field produced by an electric current. Consequently, it would be more rational to adopt the name *oersted* internationally for the unit of $\mathcal{H}$ than for the unit of R.

The following units in the C. G. S. magnetic system are thus left for the present without names;—reluctance, reluctivity, permeance, and permeability; however, these are units the names of which can be most readily spared by electrotechnicians.

For Use in the Practical System

In conformity with the Italian committee's proposal of 1927, the subcommittee unanimously adopted a practical unit of magnetic flux Φ with the value of 10^8 C. G. S. units, and with the name *pramaxwell*. (The prefix *pra* may be regarded as a contraction of the adjective "practical"—in French, "pratique"). It was also agreed to adopt the prefix *pra* as applicable for deriving practical units from corresponding C. G. S. units.

It was pointed out during the review of the subcommittee's resolutions by the main committee on nomenclature, that the *pramaxwell* as above defined was a definite unit magnitude and unit name concerning which there could be no misunderstanding or confusion; but that otherwise might be the case were attempts made to produce other practical magnetic units from the remaining members of the C. G. S. series. For instance misunderstanding and confusion might arise by using *pragilbert, praoersted, or pragauss.* This is because there are at least three different systems of "practical" units recognized today; namely, (a) the quadrant-eleventh-gram-second system of Maxwell; (b) the meter-kilogram-second system of Giorgi, and (c) the centimeter-gramseven-second system of Dellinger, Bennet, Karapetoff and Mie. Moreover, each of these three systems is sometimes claimed to be "rationalised" in modern technics, by the transfer of the factor 4π from magnetomotive force to reluctance. There might thus be at least two possible values for the "*pragilbert*" and six possible values for the "*pragauss*." Under these conditions so far as concerns the prefix *pra* it seems desirable, at least for the present, to limit the names for practical magnetic units to the *pramaxwell.* Of course the *ampere-turn* is a practical unit of magnetomotive force that has long been available and is free from ambiguity.

UNIT OF FREQUENCY

It was proposed by the German national committee to adopt the *hertz* as the international name of the unit of frequency, with the value of one cycle per second; but it was found impossible to reach agreement on this proposition, which was therefore referred back to the subcommittee for further consideration.

REACTIVE UNITS RELATING TO A-C. CIRCUITS AND SYSTEMS

The name *var* was adopted on a proposal of the Roumanian national committee, for the practical unit of reactive power in an a-c. circuit or system. This name *var* may be regarded as a contraction of the term "volt-ampere-reactif" or "reactive volt-ampere." The ordinary right-angle triangle, representing a-c. power, may thus be regarded as having *watts* for its base, *vars* for its perpendicular, and *volt-amperes* for its hypotenuse.

From the *var* the *kilovar* of 1,000 *vars* is derived in the regular way, expressible in the contracted form of *kvar.* Similarly, the product of the *var* and the hour gives rise to the *varhour,* expressible in the contraction *varh,* and likewise the *kilovar-hour* in the form *kvarh.*

It was proposed to adopt the term "hormanance" derived from a Greek verb meaning "excitation" as designating reactive power; but the motion was lost, and the matter was left for further study. It was then agreed to adopt provisionally the term "reactive power" itself. Thus, the a-c. power triangle would have *active power* as its base, *reactive power* as its perpendicular, and apparent power as its hypotenuse.

DEFINITION OF POWER FACTOR IN A SINUSOIDAL A-C. SYSTEM

In accordance with a proposal of the Roumanian national committee it was agreed to define the power factor of a sinusoidal a-c. system in the steady stat by the numerical value of the expression: $P/\sqrt{P^2 + P_r^2}$, either as a perunitage or a percentage; where P is the total active power of the system in *watts,* and P_r is the total reactive power of the system in *vars.*

DEFINITION OF POWER FACTOR IN A SINGLE-PHASE NON-SINUSOIDAL CIRCUIT

For the case of the general non-sinusoidal a-c. circuit it was agreed to adopt provisionally as the definition of the power factor, the numerical value of the expression: $P/(V\,I)$ where P is the active power in watts, and $V\,I$ is the apparent power, expressed as the product of the volts V and the amperes I.

Certain other subjects connected with reactive components in a general non-sinusoidal a-c. system were assigned for future discussion in the subcommittee, and also certain ambiguities in the use of existing electric and magnetic units. The hope was expressed that the appearance of premature and ill-considered new units in electrotechnical literature may be prevented by the work of the I. E. C. subcommittee on E&M U&M, to which the national committees may refer such questions advantageously for international consideration.

The resolutions of the Subcommittee on Electric and Magnetic Units and Magnitudes were reviewed and unanimously adopted by the main advisory committee No. 1 on nomenclature; thence reported to the plenary meeting of the I. E. C. in Oslo, July 9, 1930, where they were unanimously adopted.

NOTE: In connection with the adoption of the name *oersted* for the C. G. S. magnetic unit of magnetising force $\mathcal{H}$, as above outlined, it may be of interest to note that on June 27th, the opening day in Copenhagen, an official visit was made to the Oersted Statue in a park of that city. In the statue, Oersted is represented as observing the deflecting action of a voltaic-battery current upon a magnetic needle. With appropriate ceremonies, President Feldmann deposited at the base of the statue a suitably inscribed floral wreath.

(Signed) A. E. KENNELLY, Chairman,
Subcommittee on
Magnetic Units of the
UNITED STATES NATIONAL
COMMITTEE, I. E. C.

1929 Census of Manufactures for Electrical Apparatus Shows 39% Increase

Announcement is made by the Bureau of the Census, Washington, D. C., December 31, 1930 that, according to preliminary tabulation of data collected in the Census of Manufactures taken in 1930, the total value of electrical machinery, apparatus, and supplies manufactured during 1929 in the United States amounted to $2,323,597,927, an increase of 39.3 per cent as compared with $1,668,104,965 for 1927, the last preceding census year.

The total for 1929 consisted of: Insulated wire and cable, $296,858,831; motors, exclusive of fan motors, $185,233,201; batteries, battery parts, and supplies, $145,207,574; industrial, commercial and domestic apparatus and appliances, $100,698,743; incandescent lamps, $85,319,515; switchboards, circuit breakers, and switches $79,424,219; transformers, induction voltage regulators, and current-limiting reactors, $78,114,532; generating apparatus and parts, $68,131,815; ignition apparatus for internal-combustion engines, $54,426,944; conduits and fittings, $46,915,073; wiring devices, $43,120,093; control apparatus, $42,541,032; measuring instruments, relays, and instrument transformers, $38,328,070; electrotherapeutic and electromedical apparatus, $19,957,011; fuses and fuse blocks, $13,420,285; electric fans, $11,560,642; miscellaneous electrical equipment, $936,059,847.

Of the total, $2,217,634,994 was contributed by those engaged primarily in the manufacture of electrical machinery, apparatus, and supplies, and the remaining $105,962,933 represented the value of such commodities made as secondary products by establishments engaged primarily in other lines of manufacture.

This industry embraces establishments engaged primarily in the manufacture of machinery, apparatus, and supplies for employment directly in the generation, storage, transmission, or utilization of electric energy. It does not cover establishments whose principal products are electric-lighting fixtures, electric signs, or motor-driven tools, mechanical refrigerators, washing machines, or other machines and appliances constructed with built-in motors, ignition apparatus, or other electrical equipment, unless the electrical equipment is made by the manufacturers of the machines or appliances and its value constitutes at least one-half of the total value of the machines or appliances.

Table I, below, gives summary statistics for the industry, for 1929 and 1927; Table II shows the values of the several broad classes or groups of products manufactured in 1929 and 1927. The figures for 1929 are preliminary and subject to revision.

TABLE I—SUMMARY FOR THE INDUSTRY: 1929 AND 1927

	1929	1927	Per cent of increase or decrease (−)
Number of establishments	1,798	1,177	1.2
Wage earners (average for the year)[1]	329,361	241,566	36.3
Wages[2]	$455,294,638	$336,238,750	35.4
Cost of materials, containers for products, fuel, and purchased electric current[2]	$921,190,963	$645,761,699	42.7
Products, total value[2]	$2,286,273,042	$1,637,307,035	39.6
Electrical machinery, apparatus, and supplies	$2,217,634,994	$1,551,816,138	42.9
Other products, and receipts for repairing	$68,638,048	$85,490,897	−19.7
Value added by manufacture[3]	$1,365,082,079	$991,545,336	37.7

[1] Not including salaried employees. The average number of wage earners is based on the numbers reported for the several months of the year. Because of the fact that manufacturers report the numbers employed on or about the 15th day of each month, as shown by the pay rolls, usually taking no account of the possibility that some or all of the wage earners may have been on part time or for some other reason may not actually have worked the entire month, this average somewhat exceeds the number that would have been required for the work performed if all had been continuously employed throughout the year. Thus in some cases the number reported for a given month exceeds the average for that month.

[2] Manufacturers' profits cannot be calculated from the census figures because no data are collected for certain expense items, such as interest on investment, rent, depreciation, taxes, insurance, and advertising.

[3] Value of products less cost of materials, containers for products, fuel, and purchased electric current.

TABLE II—ELECTRICAL APPARATUS, AND SUPPLIES PRODUCTION, BY CLASS AND VALUE: 1929 AND 1927

Class	1929	1927
Electrical machinery, apparatus, and supplies, all industries:		
Aggregate value	$2,328,597,927	$1,668,104,965
Made in the "Electrical machinery, apparatus and supplies" industry	$2,217,634,994	$1,551,816,138
Made as secondary products in other industries	105,962,933	116,288,827
Batteries, battery parts, and supplies	$145,207,574	*$146,693,521
Conduits and fittings	46,915,078	42,132,936
Control apparatus	42,451,032	*30,783,452
Fans, electric (including motors)	11,560,642	10,755,001
Electrotherapeutic and electromedical (including dental) apparatus	19,957,011	16,149,405
Fuses	10,784,689	8,811,050
Fuse blocks	2,635,596	2,080,192
Generating apparatus and parts	68,131,815	*104,246,026
Ignition apparatus for internal-combustion engines	54,426,944	35,123,296
Industrial, commercial, and domestic apparatus and appliances:		
Industrial and commercial	23,808,290	12,761,010
Domestic (household)	76,890,453	77,519,218
Instruments—measuring, relays, and instrument transformers	38,328,070	34,133,212
Lamps, incandescent-filament (not including sockets and other fittings)	85,319,515	87,933,244
Motors, except fan motors (not including starters or controllers)	185,233,201	*111,819,855
Switchboards, circuit breakers, and switches	79,424,219	71,924,341
Transformers, induction voltage regulators, and current-limiting reactors (except radio and measuring-instrument transformers)	78,114,532	*66,266,216
Insulated wire and cable	296,858,831	210,047,947
Wiring devices	43,120,093	32,703,331
Miscellaneous	936,059,847	578,350,676

*Revised.

Winter Convention To Be Reported Upon

As this issue of ELECTRICAL ENGINEERING goes to press, the major technical meeting of the Institute, the winter convention, is assembling in the Engineering Societies Building at 33 West 39th Street, New York. Early registrations presage a heavy attendance and indicate a wide general interest in the fifty papers to be presented at ten technical sessions.

In the March issue ELECTRICAL ENGINEERING will present a news story covering the principal features of the gathering. If discussors of papers presented cooperate sufficiently promptly, there also will appear in that issue a resume of important discussions; otherwise they will appear in a subsequent issue.

Another Welding Essay Prize Contest Announced

For the purpose of increasing "the knowledge of the adaptability of arc welding to industry more especially of the adaptability of welding in the redesign of present machinery cast-iron or riveted steel structures to welded steel structures" the Lincoln Electric Company of Lincoln, Ohio, has announced its second arc welding prize competition. A total of $17,500 in prizes is offered, divided as follows:

First-Prize Paper	$7,500
Second-Prize Paper	3,500
Third-Prize Paper	1,500
Fourth-Prize Paper	750
Fifth-Prize Paper	500
Sixth-Prize Paper	250
Seventh to Forty-First Prize Papers	100

According to the announcement any person or group of two or more persons in any country of the world may submit a paper in this competition. However, mandatory requirements listed by the Lincoln Company include: (1) Only one paper from any competitor or group; (2) debarment of all Lincoln Company employees; (3) actual participation by each contributor in the work that forms the subject matter of his paper; (4) that descriptions be practical and readily understandable; (5) the machine or structure described must actually have been designed; (6) subject and illustrative matter must be in the English language; and (7) manuscripts must be mailed prior to October 1, 1931, arriving in Cleveland on or before October 31, 1931.

It is stated also that the subject matter of a paper submitted in the prize contest must come under one of the two following headings:

"(A) A description of a useful machine, structure, or building previously made in some other way that has been redesigned in whole or in part, so that arc welding is applied to its manufacture.

(B) A description of a machine, structure, or building not previously made that has been designed in whole or in part to the use of arc welding and a description showing how a useful result is obtained which was impractical by means of other methods of manufacture. It is not necessary that the machine as redesigned should have been manufactured at the time of writing the paper."

Details and further information are available from the Lincoln Electric Company, P. O. Box 683, Cleveland, Ohio.

American-Scandinavian Fellowships Due for Consideration

In April, 1931, the American-Scandinavian Foundation will award to students of American birth a number of traveling fellowships for study in Scandinavian countries during the academic year 1931-1932, each fellowship to carry with it a salary of $1,000.

Graduate students and younger instructors and professors in American colleges are especially urged to become candidates; and it is preferred that all applications first be considered by their suitable college or university authorities.

Chairman of the final jury of award is Professor William Hovgaard of M. I. T. and as the meeting of the jury takes place in April, it is of importance that all nominations be well in hand by March 1st.

Send for details to Neilson Abeel, Secretary to the Foundation, 25 West Forty-Fifth Street, New York, N. Y. He will gladly supply application blanks and full information as to course of further procedure.

◆

Lehigh University Announces Fellowships

Up to April 1st, C. R. Richards, president of Lehigh University will receive applications for fellowships in Lehigh's Institute of Research, as follows:

One: Henry Marison Byllesby Research Fellowship in any branch of science or technology dealing with technical problems of interest to the public utilities.

One: James Ward Packard Research Fellowship in electrical or mechanical engineering,

One: C. Kemble Baldwin Research Fellowship in any branch of science having a direct bearing on aeronautical engineering.

Two or more: Institute of Research Fellowships.

Stipends for these several fellowships will be $750 for the Byllesby, Baldwin, and Packard and $600 for the Institute of Research Fellowship, for each ten-month period, with freedom from tuition fees.

Applicants are requested to present full statement of training and experience; also a transcript of academic record, list of references, and a recent photograph.

◆

Yale Again Offers The Sterling Fellowships

Fellowships established by a gift of one million dollars from the trustees of the estate of the late John W. Sterling are offered again by Yale University, open to its own graduates and graduates of other approved universities and colleges in the United States and foreign countries, be they men or women professors or, instructors on leave of absence who wish to pursue studies and investigations under the direction of the faculty of the Graduate School at Yale or in affiliation with that body.

Stipends of the Fellowships range from $1,000 to $2,500 and more, dependent upon previous experience of the recipient and the character of the proposed investigation.

Applications must be submitted by March 1, 1931, addressed to Edgar S. Furniss, Dean of the Graduate School of Yale University, New Haven, Connecticut, upon blanks which may be obtained from him.

◆

Columbia University Offers E. E. Scholarships

Each year the governing bodies of Columbia University have placed at the disposal of the Institute a scholarship in Electrical Engineering in the School of Mines, Engineering, and Chemistry of Columbia University, for each class. The scholarship pays $350 toward the annual tuition fees which vary from $340 to $360, according to the details of the course selected. Reappointment of a student to the scholarship for the completion of his course is conditioned upon the maintenance of good standing in his work.

Applicants must meet the regular admission requirements, and all letters of application addressed to F. L. Hutchinson, the National Secretary, A. I. E. E., 33 West 39th St., New York, N. Y., should give age of candidate, place of birth, education, references, photograph, and reference to any other activities, such as athletics or working one's way through college. The last day for filing applications for the year 1931-32 will be June 1, 1931.

The course at the Columbia School of Mines, Engineering, and Chemistry is a three-year course on a graduate basis. Candidates must have had a general education, including considerable work in mathematics, physics, and chemistry. Three years of preparatory work with special attention to the three preparatory subjects mentioned in a good college or scientific school should be sufficient. A college graduate with a B. S. degree in engineering can generally qualify to advantage. The candidate is admitted on the basis of his previous collegiate record without undergoing special examination. Other qualifications being equal, members of Student Branches of the A. I. E. E. will be given preference.

The purpose of this advanced course is to produce a high type of engineer, trained in the humanities as well as in the fundamentals of his profession. It is hoped that Enrolled Students and others qualified will show a keen interest in this scholarship.

◆

Subway Noise Given Technical Attention

In the January issue of Electrical Engineering appeared a few of the facts on "Noise Measurement" as recently placed before the Middle Eastern District Meeting at Philadelphia, by John C. Steinberg, telephone quality engineer for the Bell Telephone Laboratories.

Offering encouragement to Mr. Steinberg's efforts there has now been appointed by the Board of Transportation of the City of New York, a group of acoustical engineers to make technical study of noises resulting from elevated and subway traffic, and to return a report upon applications possible to limit or eliminate these noises.

G. T. Stanton, acoustic consulting superintendent of Electrical Research Products, Inc., and an Associate of the Institute, has been given charge of these investigations and is carrying on tests to discover the exact causes of these noises and just where their volume is greatest. A test trip to the Battery reported in the daily press seemed to demonstrate that without a doubt the acceleration of motors is directly responsible for the greatest amount of noise emanating from any single source. Except in instances where one train was passing another, the highest level of noise was *inside* of the cars and not outside upon the tracks as most riders would suppose, the bulk of the noise appearing to be attributable to the grinding of gears, motors, and wheels beneath the car floor. With no ready escape in this region, the noises reverberate within the car causing a greatly increased volume of sound.

St. Lawrence Commission Wants Immediate Action

The immediate creation of a public "Power Authority" for the International Section of the St. Lawrence River development has been recommended to Governor Roosevelt and the New York Legislature by the Saint Lawrence Power Development Commission of which Robert M. Haig is chairman.

An engineering report has been made covering the project, and to quote the commission, "it has been found entirely practicable to construct the necessary project . . . utilizing existing transmission and distribution systems . . . under contract with operating companies to assure them fair remuneration for their services and assure to the consumer the advantages of low-cost power . . . Terms of such contract to be worked out upon basis of actual cost for generating, transmitting and distributing power.

"It is estimated that by 1937 the total generation of power in New York State will exceed 20,000,000,000 kw-hr. as compared with 13,000,000,000 kw-hr. in 1929."

Departing from many plans previously offered by Canadian and American engineering groups, the Commission recommends a one-dam, two-step development at Messena Point, New York—farther down stream than priorly considered, which it contends will "reduce construction costs, construction time, produce more power with the flooding of a minimum acreage and make for the elimination of the more serious hazard of building power house and spillway on what is now dry land."

By the New York press, the whole situation appears to be looked upon as largely a political development.

◆

The Midwest Power Conference Meets at Chicago in February

In view of the existing economic conditions and the relation between business economics and the power industry, what promises to be the most significant conference on power machinery for years will be held in Chicago February 10-14, inclusive, when nationally recognized authorities on power will address the Fifth Midwest Power Engineering Conference, and the Fourth National Fuels Meeting of the American Society of Mechanical Engineers at the Stevens Hotel.

Simultaneously, the Midwest Engineering Exposition will present at the Coliseum a "cross-section" of the newest developments in power machinery and appliances: G. E. Pfisterer, who is managing director of the exposition, reports that a realization of the absolute necessity of revaluating the many factors in power economics to meet both present and future conditions has created an unusually keen interest in this forthcoming event, which will not only present important possibilities to the experienced engineers but will also offer to young engineers the opportunity in a common meeting place for an interchange of views, the forming of contracts, and assimilation of the latest developments in the field of engineering.

Upward of 200 leading manufacturers of power machinery and appliances have engaged display space and all arrows seem to point to a full occupancy of the 85,000 square feet available at the Coliseum. Unusual exhibits of heating, ventilating and refrigerating machinery, demonstrating the gains which have been made in these various branches and further development along new lines, seems assured. The refrigerating industry, especially, is in a state of flux and the newer methods and appliances which will be displayed at this exhibition should be of intense interest.

Another important field will be that of generation, utilization and distribution of power, covering as it does the entire range of the power industry. Engineers will be able to study their specific problems, as many of the demonstrations will be by actual operation.

◆

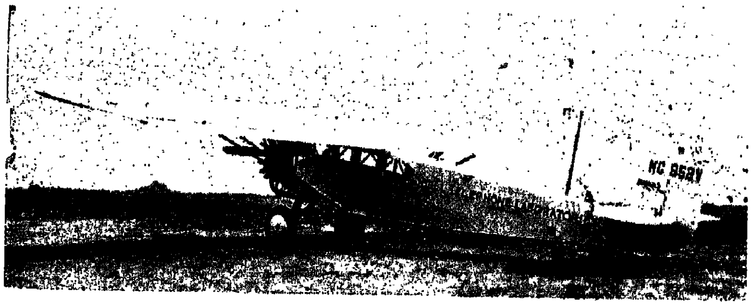
Shall Advertising Menace Radio Programs?

That the real usefulness and benefit of radio program possibility is being materially hampered if not actually jeopardized by a superabundance of the commercial advertising element was stressed by Doctor Lee de Forest, retiring president of the Institute of Radio Engineers in his farewell address on the evening of January 6th. Doctor de Forest is quoted as having asserted that the present "state of affairs is an unhealthy one and gives alarming symptoms for the future . . . that advertising from the local stations has become so uncontrolled that one wonders at the patience of a suffering public."

Just what may be done to reduce or eliminate this so-called "cancerous growth" remains for the future to discover; it would appear that much of the sales talk and cheap mediocrity of advertising program selections now being broadcast might well be dispensed with and result in very real benefit to public listeners.

◆ ◆ ◆

Aircraft Radio Development Continues



FAIRCHILD 71-A monoplane acquired recently by the Bell Telephone Laboratories, New York, for further practical experimentation in two-way radio communication between planes and between planes and ground stations. Long- and short-wave equipment is installed, powered by a small dynamotor in conjunction with a storage battery.

That police officers patrolling a city from the air may actually be in closer touch with headquarters than the patrolman on the street was demonstrated in a recent practical experiment. Officials in this plane, officials in the laboratories' Ford plane, and officials in the New York police commissioner's office were participants in two-way and three-way communication between the planes and between the planes and ground, while the two planes were aloft over two widely separated parts of the city.

Some of the possibilities immediately suggesting themselves include the pursuit of criminals operating in high-powered automobiles, the untangling of highway traffic jams, and cooperation with fire departments in large water-front or industrial fires.

New Recommendations for Electricity on Shipboard

A 1930 edition of "Recommended practise for Electrical Installations on Shipboard" has just become available. The pamphlet, which was originally known as "Marine Rules" has been developed under the auspices of the A. I. E. E. committee on application to marine work and in its new edition includes extensive revision of the 1927 issue, with considerable of new material on such points as motor-operated, water-tight doors, electric brakes, radio compasses, etc. It is known as Section 45 in the Institute's Standards series, and is on sale at a price of $1.50 per copy with a 50 per cent discount to Institute members.

◆

A $5,000 X-Ray Screw Driver

According to recent press reports from Stanford University (California) the versatile X-ray has been harnessed to the lowly task of driving screws.

It is said that P. A. Ross, the inventor, physics professor at Stanford, uses his machine as demonstrable support for the theory that X-rays behave like bullets rather than like waves, as is popularly believed. His equipment consists principally of an X-ray spectrometer. Indications are that the new device will not, however, at once displace the ordinary household tool, for it admittedly requires a lot of screw-driving to warrant a $5,000 implement. But it is stimulating, to allow free rein to the imagination in considering some of the many possibilities of little-known forces.

◆

East River Tube Projected for New York

It is reported that the War Department at Washington already has approved proposed construction of $50,000,000 twin vehicular tunnels under the East River, New York, the city being committed to the project by an appropriation of $350,000 for borings, engineering studies, and estimates. Actual report by the city's Board of Transportation has not yet been forthcoming, and John H. Delaney, chairman is quoted as having stated that "recommendations would probably be made within the next three months."

The tubes would connect Borden Avenue, Queens, with East 37th and 38th Streets, Manhattan, and would form the eastern third of a vehicular channel proposed for fast middle-Manhattan crosstown traffic, ultimately to cross Manhattan underground to the Hudson River and thence to Weehawken, N. J., via another bore. Preliminary investigations have been completed, and the issue awaited now seems to be an economic one to prove or disprove its feasibility.

◆

Nearly 14 Million Miles Phone Wire in New York City Area

New York City is served by 9,400,000 mi. of telephone wire, about 495,000 mi. of which was installed during 1930, according to a review for the year issued today by J. S. McCulloh, president of the New York Telephone Company. Manhattan alone has a total of 3,734,000 mi. of wire, of which 254,000 were added during the year.

More than 98 per cent. of all telephone wire mileage is now enclosed in storm-proof cable, the report shows. Twenty new central offices, including nine in New York City, installed in 1930 bring the total in service in the company's territory to 494. The wire mileage interconnecting the telephones served by the company was increased in 1930 by 948,000 to a present total of 13,750,000 mi.

Vestal Copyright Bill Recommended

Edwin J. Prindle, chairman of the Pentent Committee, has recommended that the American Engineering Council endorse the Vestal Copyright Bill, H. R. 12549. This House bill provides (1) for automatic copyright, (2) that the author may divide such copyright into separate ways in which it is capable of utilization, (3) that all authors, be they American or foreign, will have automatic copyright in all countries which are members of the International Copyright Union, (4) that the term of copyright will be for the life of the author and fifty years after his death, and (5) that prints and labels for articles of manufacture are included in said copyright.

Japanese Professor Arrives for Study of Electronics

Masaharu Hoshiai, assistant professor of electrical engineering at Tokyo Imperial University is now in New York, having been sent to America for a year's stay by the Denki-Gakkwai—the Institute of Electrical Engineers of Japan—under a grant from the Iwadare Fund for the encouragement of electrical science. Professor Hoshiai is the first person selected under this endowment.

Professor Hoshiai was graduated from the electrical engineering course of the Imperial University in 1922 and has since devoted his time to the study and teaching of electrical science at that University. The purpose of his visit is to extend his knowledge of applied electronics. Mail can be addressed to him in care of W. H. Capen, International Standard Electric Corporation, 67 Broad Street, New York City.

◆

Civil Engineers Elect Francis Lee Stuart

The opening session of its Wednesday morning meeting, January 21, saw the installation of Francis Lee Stuart, consulting engineer for the City of New York, as President of the American Society of Civil Engineers. As chief engineer of the Baltimore & Ohio Railroad from 1910 to 1915 and subsequently its consulting engineer, Mr. Stuart is of course well known in all railway and transportation circles. He has served also as chairman of the budget committee of the U. S. Railroad Administration in 1919 and in 1920 acted as consulting engineer to the Hydro-Electric Power Commission of Ontario (Canada).

In assuming his new office Mr. Stuart's message was directed toward the present critical situation facing business and industry and stressed the vital importance of the engineer's duty toward ultimate adjustment of financial, managerial, and economic complications through a better understanding of cause and effect.

Research and investigational activities of government bureaus in their importance to the engineering profession consumes the balance of Wednesday. In attendance at that meeting were George K. Burgess, director of the Bureau of Standards; J. D. Sears, administrative geologist of the United States Geological Survey; Major-General Lytle Brown, chief of U. S. Engineers, S. H. McCrory, and others of eminence.

The place of the civil engineer in the planning of cities, the prequalifications of highway contractors, and the use of natural gas for the generation of steam power, afforded no little food for debate. Thursday offered a full day for the discussion of these and several other interesting themes.

Friday closed the convention with excursions to New Jersey to inspect the recently constructed terminal of the Lackawanna Railroad, facilities of the

Newark airport and important highway and bridge construction now going forward under the direction of the New Jersey Highway Commission.

Social functions of the meeting included a dinner dance at the Roosevelt Hotel Wednesday evening, when Honorary Membership in the Society was conferred upon John R. Freeman, nationally known hydraulic engineer; and a smoker Thursday evening at which Doctor Roy Chapman Andrews told of his recent expedition to Central America. Approximately two thousand engineers from more remote sections of the country as well as those in proximity to the East attended and benefitted by the fellowship of the meeting.

Television Again Demonstrated

Previous application of this marvel of science has been so restricted to test and experiment that the "running public" have quite "counted themselves out" as a matter of course. Now things seem to be getting along and on January 7th, a "television tea" was given by Bell Telephone Laboratories and the American Telephone and Telegraph Company, jointly, when one group of woman guests gathered at one location were called separately to the telephone to greet "in person" the several members of a group at the other location. Many of these guests were members of the Woman's Engineering Club, and the tea proved highly instructive as well as diversive.

In this same field the use of television is being debated as an adjunct to police forces, to supplement police radio broadcasting already in action. Pictures of fugitives from justice would appear across the television screen in station houses or police patrol cars and the police would be given an actual visual knowledge of the person or persons to be apprehended. Chicago already is pioneering in this tryout as to the feasibility of police television and the authorities there after witnessing a demonstration through the *Chicago Daily News* experimental television station have recommended the adoption of visual radio in direction against and detection of crime. Mr. Wade, president of the Western Television Corporation of Chicago, by whom the demonstration was made, explained that the police department could have its own television transmitting station with television receivers in each outlying station house and that the police cruising cars now equipped with shortwave receivers could have also television receivers.

N. Y. Electrical Association Elects New Officers

Clarence L. Law, Associate A. I. E. E., general commercial manager of the New York Edison Company, and assistant to the vice-president of the Yonkers Electric Light and Power Company, was elected yesterday to the presidency of the Electrical Association of New York at its annual meeting at its headquarters, 100 East Forty-fifth Street.

Mr. Law succeeds Earl Whitehorne, assistant vice-president of the McGraw-Hill Publishing Company. Others elected at the association's meeting were Theodore H. Joseph, first vice-president; A. Lincoln Bush, second vice-president; H. H. Barnes, jr., third vice-president; Frank A. Pattison, fourth vice-president; L. L. Strauss, treasurer; Edward Ingraham, secretary, and J. A. Corcoran, assistant secretary.

◆

San Antonio Now has High-Pressure Plant

What is said to be the highest-pressure steam-electric generating unit now in commercial operation recently was placed in operation by the San Antonio Public Service Company in its Conception Road station. There the company has rebuilt what is generally known as Station B, by adding an 8,000-kv-a. unit to the 12,500-kw. unit of the original layout.

The rebuilt plant now consists of a 20,000-kw. compound unit designed for a maximum of 1,400 lb. pressure with a temperature of 825 deg. fahr. at the throttle. The combined units operate in parallel connection to the busbars and the old unit now constitutes the low-pressure stage of the whole, with an operating pressure of 175 lb., 550 deg.

Another interesting feature of the rebuilt is that the new high-pressure boiler is installed in the already existing boiler room, with the roof raised to accommodate the new equipment; the air heater and economizer are located outside of the building.

Another advantage, especially in this locality, lies in the fact that although the unit is designed primarily for oil firing, a natural gas fuel may be used if desired. With the installation of turning gears, the adjacent larger units will now be used for standby purposes or to handle peak loads. The company's engineers are most enthusiastic over these gears and are endorsing their further application on other standby units of the system.

American Engineering Council

A. E. C. will Participate in Washington Celebration

By special invitation from the George Washington Bicentennial Commission, and a set of resolutions approved and adopted at its last board meeting, the American Engineering Council will participate in plans for the national celebration of the 200th anniversary of the birth of George Washington, America's first engineer president.

By these resolutions, a copy of which was transmitted to S. Bloom, director of the commission, and incorporated in the official proceedings of the meeting, the Council pledges its earnest cooperation with the commission in such ways as may open to further the completeness of plans for suitable observance of this memorial date.

◆

Engineers Aid Hoover's Employment Committee

As the outgrowth of a conference of representatives of architects, contractors, engineers, and the steel, cement, and lumber industries called by Col. Arthur Woods, chairman of President Hoover's emergency committee for employment, there has been formed a public and semi-public works section of that committee. The purpose of that section is to endeavor to ascertain why works projects already authorized and for which appropriations have been made are not going forward, discovering if possible ways and means of expediting them so that the work will be undertaken promptly.

General C. W. Kutz, Corps of Engineers, U. S. A., (retired) is serving as the American Engineering Council's representative in this work, and the American Society of Civil Engineers has requested its local sections to serve as the principal field agencies for collecting necessary information. Emergency bills passed by Congress have removed some inhibitions of existing law or regulations in so far as the federal work is concerned and there are other bills pending which, if passed, will remove other impediments.

The President's emergency committee also desires to collect through the American Engineering Council information regarding any efforts made by employers to stabilize employment during the present emergency and any permanent plans adopted. Sections of the Institute and the American Society of Mechanical Engineers were requested in December to undertake this task. Results of their surveys give much of the desired information regarding employment conditions in the various industrial centers and the efforts of local organizations to bring about improvements.

A pamphlet entitled "Outline of Industrial Policies and Practises in Time of Reduced Operation and Employment" has been prepared for the emergency committee, and copies may be secured by addressing the committee, Department of Commerce Building, Washington, D. C.

A. E. C. Officers Elected at Annual Meeting; Business Stabilization Plans are Discussed

C. E. GRUNSKY, re-elected president of the American Engineering Council, presided at its annual meeting held at the Mayflower Hotel in Washington, D. C., Jan. 16-17, 1931. Other officers elected for the coming year included O. H. Koch of Dallas, Texas, and D. Robert Yarnell of Philadelphia, as vice-presidents; H. E. Howe of Washington, treasurer (re-elected); and Lawrence W. Wallace of Washington, executive secretary (re-elected). The other two vice-presidents, who continue for another year, are, Lewis Buckley Stillwell of New York and Gardner S. Williams of Ann Arbor, Mich.

Actions of importance to the nation, of interest to the engineering profession as a whole, and of particular interest to many individuals among the 59,000 professional engineers which it represents, were taken by the Council. These are outlined in the following paragraphs.

BUSINESS STABILIZATION

Seven principal points of attack on the problem of accomplishing business stabilization were recommended in a report prepared by a committee headed by Ralph E. Flanders of Springfield, Vt., vice-president of the American Society of Mechanical Engineers. The report recommended in part:

> (1) Maintaining or increasing the consumption of goods and services; (2) balancing plant, machinery and processes against production demands; (3) balancing distribution agencies against consumer requirements; (4) balancing manpower against production and distribution demands; (5) controlling money and credit to satisfy the needs of government, business, and the individual; (6) encouraging research activity to increase human well-being through development and progress in industry and business; balancing public works against public need.

The Council authorized its administrative board, and through it the executive committee, to take such steps as may be desirable to bring about such measures as the report recommends.

Further appropriations by the federal government to relieve the present depression were disapproved, and the proposal of a federal bond of 1,000 million dollars to construct public works was specifically opposed by the assembly, the legislative organ of the Council. Acting upon the recommendations of a committee headed by L. B. Stillwell of New York, the assembly opposed plans advocated by various organizations and individuals looking to the issuance by the federal government of large amounts of bonds for emergency construction work, on the grounds that:

> The organization and facilities of the several departments of the government, which under the law must direct this work, would not be able to expend with reasonable efficiency and within a period of two years any large amount in addition to the appropriations already made. Sums already made available by the federal, state, and municipal governments by the railroads, public utilities, and other corporations, are so large in the aggregate as to make the effect of an additional billion dollars which might be appropriated relatively of secondary or minor importance.

RECOMMENDATIONS ON FEDERAL PROJECTS

Establishment of a federal department of public works was urged by Major Gardner S. Williams, in his report as chairman of the committee on government reorganization. Major Williams stated the belief that the measure would not meet with as much opposition this time as previously experienced; and that it was becoming generally recognized that if such a department had been in existence for the past ten years or more a great deal of the present confusion in connection with the emergency construction of public works would have been avoided.

Opposition to all Muscle Shoals bills that contemplate government ownership or operation, or that set aside the intent and purpose of the Federal Water Power Act was reaffirmed by the Council.

A special committee appointed to study the McNary-Parker bills, which provide for the establishment and development of American transport services overseas, to encourage construction of American airships and other aircraft in the United States by American capital for use in foreign commerce and for other purposes, recommended that the Council support these bills in principle and allow the committee time for further study. The Council approved the recommendation.

The Council voted to use its influence to secure the appropriations necessary to the restoration of the locks in the Norfolk-Florida Canal.

Acting upon a carefully prepared recommendation of the Washington Society of Engineers, the Assembly voted:

> (1) That the Council strongly endorse the principle of the federal government paying all the necessary expenses of transporting civilian engineer employees, their dependents, and household effects, incurred by a change of station under competent orders. And since the executive committee of the interdepartmental board on simplified office procedure, office of the chief coordinator, now has under consideration a proposed act to provide for change-of-station allowances—
>
> (2) that a proper representative of the Council confer with the committee for the purpose of acquainting the committee with the Council's very keen interest in the matter, and with its desire to correct any inequities prevailing and to work with the committee to the end that any legislation it finally proposes will conform to the expressed desires of the Council.
>
> (3) That the Washington Society of Engineers be asked to continue its special committee so that the Council may call upon it from time to time for information and advice as the work proceeds.

PRESIDENT GRUNSKY'S SUGGESTIONS

A special committee appointed to study the president's speech at the opening of this session of the Council, found three important suggestions in the president's address which should receive careful consideration. The first suggestion, concerning the minimum height of bridges over navigable waters, was referred to the Council's committee on bridges.

The committee recommended that L. W. Wallace, executive secretary of the Council, be requested to take up with the Society of Naval Architects the matter of the maximum size of merchant ships in relation to docks and canals, and if possible secure their advice and opinion.

The third suggestion, concerning the important question of the conservation of natural water resources, was referred to the Council's committee on water resources.

ACTION ON CONGRESSIONAL BILLS

The Assembly, at the recommendation of the Committee on Public Affairs, considered a number of bills now pending in Congress, and voted on the attitude of the Council in regard to them. The Assembly voted actively to oppose S.5209, S.4819, and S.4938,—three bills on the subject of road legislation. The Council will support H. R. 13576, another road bill, and bills S.4791 and S.5021 concerning federal building programs.

The subject of a new naval towing tank in Washington was considered by the Council, and the following resolution passed:

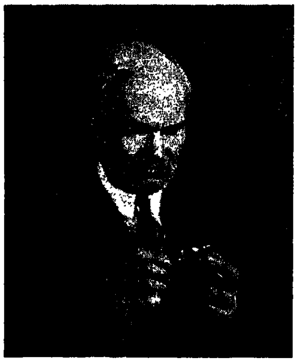
> *Whereas*, the present naval towing tank in Washington, D. C., is inadequate for modern experimentation and not equal in size and other facilities to those maintained by the most modern and progressive nations, and
>
> *Whereas*, the Navy Department is requesting an appropriation for the construction of a new naval towing tank along the Potomac in the vicinity of Cabin John Bridge, and
>
> *Whereas*, the American Engineering Council has supported similar projects for the benefit of scientific research in other departments, as for example, the National Hydraulic Laboratory at the Bureau of Standards, and
>
> *Whereas*, such an experimental model basin as proposed by the Navy would contribute incalculable values in keeping the United States in the forefront of naval construction and design,
>
> *Be it resolved*, that the public affairs committee recommends that the American Engineering Council endorse this project and appoint a special committee to confer with the naval authorities and members of Congress and offer to these agencies any practical assistance in securing the enactment of legislation looking to the creation of a new model basin towing tank.

The Assembly acted favorably upon the application of the Colorado Engineering Council, Denver, for membership in the American Engineering Council, and welcomed their representative, R. C. Gowdy, chief engineer of the Colorado and Southern Railway Company. Appointment of a representative on a joint committee to study prequalifications for contractors was authorized, but the Assembly declined to express its opinion at this time as to the advisability of such prequalifications.

Representatives of the American Institute of Electrical Engineers in attendance were A. W. Berresford, C. O. Bickelhaupt, F. J. Chesterman, M. M. Fowler, F. L. Hutchinson, W. S. Lee, William McClellan, L. F. Morehouse, I. E. Moultrop, Farley Osgood, W. S. Rodman, R. F. Schuchardt, Charles F. Scott, C. E. Skinner, Harold B. Smith and L. B. Stillwell.

Personal

LEE DE FOREST, retiring president of the Institute of Radio Engineers, and Fellow of the A. I. E. E., was born at Council Bluffs, Iowa. In 1896 he was graduated from Sheffield Scientific School of Yale University with the degree of B. S.; in 1899 he received his Ph. D., and in 1926 D. Sc., both from Yale. He has been identified with radio since the year 1901; in 1906 he patented the audion or three-element vacuum tube, and in the years that followed became an active worker in its various applications. Doctor de Forest has been the recipient of many honors, among them the Gold Medal of the St. Louis Exposition in 1904 for work on wireless telegraphy, the Gold Medal of the San Francisco Exposition in 1915 for his work in radiotelephony; the cross of the Legion of Honor from France; the Elliott Cresson Medal from the Franklin Institute; the Medal of Honor from the Institute of Radio Engineers, and the John Scott Medal from the City of Philadelphia.



LEE DE FOREST

Doctor de Forest assumed the presidency of the I. R. E. January 1930.

◆

RAY H. MANSON, a member of the Board of Direction of the Institute of Radio Engineers (1928), and a member of the A. I. E. E. since 1902, has been chosen president of the radio engineers, taking office at the recent January meeting.

He was born at Bath, Maine, was graduated from the University of Maine in 1898, and received his degree of E. E. from that institution in 1921. From 1899 to 1900 he was employed in the telephone manufacturing department and the electrical laboratory of the Western Electric Company in Chicago; the next four years were spent in the engineering and sales departments of the Kellogg Switchboard and Supply Company, Chicago. Then for a long period—until 1916—he was connected with the Dean Electric Company and its successor, the Garford Manufacturing Company of Elyria, Ohio, where for the last four years his service was as chief engineer. Since that date he has been busy with the Stromberg Carlson Telephone Company, Rochester, and is now its chief engineer and one of its vice-presidents.

During his affiliation with the manufacturing business, he has taken out over fifty patents on inventions in telephone, phonograph, and radio fields. He has been active also in radio standardization work in the radio division of the National Electric Light Association and is now chairman of its technical committee; for several years, he has been serving also as chairman of the electro-acoustic subcommittee of the I. R. E.

RAY H. MANSON

◆

ROBERT LEE WILSON, Fellow A. I. E. E and assistant to the president of the Westinghouse Electric and Manufacturing Company has resigned from that position. Mr. Wilson's resignation became effective December 31, 1930. While he will devote himself mainly to his private affairs, he will be retained by the Westinghouse Company on call in a consultative capacity, according to the statement made by F. A. Merrick, president of the company, in accepting the resignation.

In 37 years of service with Westinghouse Mr. Wilson rose from apprentice to draftsman, to inspector, road engineer, district engineer, superintendent of construction, superintendent of railway construction, assistant general superintendent, works manager, and then assistant to the president.

Born in Shelbyville, Ill., January 29, 1871, he was the son of Dr. William G. and Frances Anna (Lee) Wilson, who had moved to Illinois from Hartford county, Maryland. Mr. Wilson received his preliminary education in the public schools of Shelbyville, attended the University of Iowa for one year and Rose Polytechnic Institute, Terre Haute, Ind. for three years, graduating from the latter institution with the degree of bachelor of science in mechanical engineering in 1892. He took one year of post graduate work in electrical engineering at Johns Hopkins and started work for Westinghouse in 1894. He married Fanny Hampton Jeffers Kennard of Pittsburgh in 1900.

From 1903 to 1905, while he was district engineer with headquarters in New York, Mr. Wilson superintended the original electrification of the elevated and subway lines. While he was superintendent of railway construction from 1906 to 1909, he handled the biggest job ever undertaken by Westinghouse, the construction and installation of equipment for the electrification of the New York, New Haven and Hartford railway and the St. Clair tunnel of the Grand Trunk railroad. Much reconstruction work was necessary on these contracts; they were the first two important a-c. railroad electrification projects in the United States.

Mr. Wilson was one of the first industrial leaders to advocate elective representation in works councils and the amicable adjustment of disputes by joint conference committees representing management and employes. Recognition of his fairness and his service in employment and welfare work has come from all divisions of the Westinghouse organization. He was elected a member of the board of directors of the Westinghouse Veteran Employes' Association and has also been very active in other shop organizations.

◆

T. S. Perkins, formerly manager of supply engineering and consulting engineer for Westinghouse Electric & Manufacturing Company, has with the first of the year become its general manager of distribution engineering and will represent S. M. Kintner, assistant vice-president, in his work with several departments. Already Mr. Perkins has done much creditable work in his solution of complicated problems in the supply engineering department and standardization of production and design. R. W. Owens becomes general manager of industrial engineering and will represent Mr. Kintner in another group of the Westinghouse departments; most of his work has been in connection with motor engineering and he now falls into the field of the supervision of industrial motors, control, small motors and industrial heating engineering. At the Sharon works, W. M. McConahey has been appointed consulting engineer with headquarters in the transformer department, H. V. Putnam to succeed him as manager of the transformer engineering department. Other important changes effective January 1, 1931, are the appointment of M. S. Hancock as assistant manager of of the industrial motor engineering department and R. E. Marbury as assistant manager of the supply engineering department.

◆

W. S. Conlon has been named as successor to J. C. Williams, city engineer for Stamford, Connecticut. His varying work in the past as executive engineer, consulting engineer, designing and construction engineer, superintendent of construction and assistant engineer and assistant superintendent of construction of buildings, docks, sewage systems, water supply, etc., should make Mr. Conlon particularly well fitted for this new public works undertaking, especially as most of the past operations have been with engineering surveys and investigations in studies and reports for public utilities, railroads, etc., such as the New York subway and elevated service, the New England Power system in Vermont, New Hampshire, Rhode Island, Connecticut and Massachusetts, and other similarly representative organizations.

◆

H. O. Stephens, I. H. Sclater and A. B. Hendricks, Jr., have been appointed assistant engineers of the power transformer department of the General Electric Company, Pittsfield, Massachusetts, of which F. F. Brand is managing engineer. Mr. Stephens will be in charge of the design of oil-immersed transformers over 7,000-kv-a., air-blast transformers, reactors, and starting auto-transformers; Mr. Sclater will have charge of transformers from 501- to 7,000-kv-a., oil-immersed current and potential transformers, radio power, and other transformers; while the design of all developmental and high-voltage testing apparatus will come under the direct charge of Mr. Henricks.

◆

G. H. Cole on January 1 was transferred from the executive division of the American Rolling Mill Company, Middletown, Ohio, to become associate director of its research division. Extensive experience in the engineering and research work as well as his earlier service in the executive division of ARMCO will aid Mr. Cole greatly no doubt in his new field of service.

◆

Roy Page, who is vice-president and general manager of the Nebraska Power Company, Omaha, Nebraska, where he has always been active in civic affairs, was elected to the board of directors of the United States National Bank at its recent annual meeting. The United States National Bank is associated with the Northwestern Bancorporation.

◆

Louis Mackler, formerly electrical engineer with L. T. M. Ralston, Inc., New York City, has been appointed consulting engineer to the P. F. O'Keefe Advertising Agency, Inc. which has offices in Boston and New York. Mr. Mackler will remain in New York.

Obituary

Edward G. Connette, president of the United Gas & Electric Corp., and an expert in field utilities, died at Lockport, New York, December 30, 1930. Mr. Connette was a native of Austin, Indiana.

In his active career he started as telegraph operator in the mechanical and engineering departments of steam railroads where he shortly became assistant superintendent. In 1889 he took charge of street railway operations in Nashville, Tenn, and as superintendent equipped them with electric apparatus including the first double-reduction type of motors. After one year he was made general manager, at the same time serving as general manager and chief engineer of the Cumberland Electric Light & Power Company, Nashville, Tenn. His next service was as vice-president and general manager of the Syracuse Rapid Transit Railway Company, from which in 1905 he transferred to general managership of Worcester Consolidated Street Railway and subsidiary companies. This in 1909 led to his choice as transportation engineer for the public service commission's First District; there, besides being in full charge of the transit bureau, he supervised equipment of the inspection bureau (including power houses, transmission lines, cars, etc.) the accident bureau and appraisal bureau. Recently he had been associated with the J. G. White Management Company of New York City; he had served also as vice-president of the Wilkes-Barre Company, president of the United Gas and Electric Corporation, the Harrisburg Light Corporation Company, the Elmira Railway and Light Company and the Lockport Light and Gas Company, which latter he was visiting at the time of his death. For five years he was vice-president of the Syracuse Rapid Transit Railway Company, and for two years vice-president of the International Railway Company at Buffalo, New York, and afterward its president. He had served also as director and member of the executive committee of his company and vice-president, director and member of the executive committee of the International Traction Company. His club connections included the Municipal Engineers, the Buffalo Club, the Old Ellicott Club, the Wanakah Club, and the Country Club of Buffalo.

◆

Eugene A. Hart, a popular and active member of the Institute's Los Angeles Section, and manager of the transmission department of the General Electric Supply Corporation, Los Angeles, died at his home in that city December 11 after an extended illness of several months.

He was born at High Point, Missouri, April 1881 and after completing high school took special courses in electrical engineering. In 1896 he started an apprenticeship with the Los Angeles Electric Company which kept him busy until 1904; then he removed to Chicago to pursue his electrical bent in the meter department of the Commonwealth Electric Company. His general duties from 1904 to 1913 were in connection with small combination gas and electric plants of the Jefferson City (Mo.) Light Heat and Power Company; when he resigned he had advanced to the office of assistant manager. He then spent 3 years in electrical contracting, after which he became assistant manager of the Missouri Public Utilities Company at Poplar Bluff. This led to a managership of the company's operations in what was known as the Lead Belt Group, at Flat River, Mo., where he built the distribution systems and transmission lines for seven towns.

In 1917, he was transferred to become manager of its southeast Missouri group (13 towns) with headquarters at Cape Girardean, Mo., work involving a combination of water, gas, electric, and street railway properties, rebuilding all departments including 160 miles of power lines. The Los Angeles Gas and Electric Company induced him to enter its distribution department in 1924. From 1925 to 1927 he was sales engineer in charge of the transmission department of the Los Angeles district of the Pacific States electric Company, predecessor of the General Electric Supply Corporation.

◆

Samuel Winthrop Dean, Associate of the Institute, died January 8, 1931, in the Massachusetts General Hospital, Boston, after a long illness.

Mr. Dean was born August 29, 1897, at Cambridge, Mass. During the war he served as Ensign in the U. S. Naval Reserve Force. After graduation with A. B. degree from Harvard University in 1919, he was employed with the Radio Corporation of America until 1925, working on transmitting and receiving radiotelegraph problems. From 1925 until his illness he was with the development and research department of the American Telephone and Telegraph Company engaged in development of long-wave receiving systems for transatlantic radiotelephony. During this period Mr. Dean spent some time in England and Scotland. He was the author of several technical papers and was granted several patents.

◆

G. Stanley Covey, assistant service foreman of The Washington Water Power Company, Spokane, Washington, and an Associate of the Institute, died in December 1930. He was born in March 1878 at Jordan Falls, Shelburne County, Nova Scotia, and after attending both high school and private school took a special course in steam engineering. Later he spent three years in the operating department of the Pacific Electric Railway Company, Los Angeles, and one year as an engineer for the Southern California Edison Company at San Bernardino. He had been with the Washington Water Power ever since 1904, where his first services was principally on the operation of motors.

◆

Huibert Doyer, a Member for Life of the Institute and for many years a resident of Clos Myriel Chaillyvillage, Lausanne, Switzerland, recently died suddenly at his home. Mr. Doyer was born in Utrecht in 1862, and was a charter member of the Institute. He was graduated from the Holland Polytechnical School in Mechanical Engineering in 1885 and for sometime thereafter worked in the physical laboratory of that institution, in an ambition to promote so far as possible the electrical industry in Holland. He became internationally prominent, and now leaves behind him a host of friends, both in the profession and in civil life.

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the addresses as they now appear on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the Secretary at 33 West 39th St., New York, N. Y.

All members are urged to notify Institute Headquarters promptly of any changes in mailing or business address, thus relieving the member of needless annoyance and assuming prompt delivery of Institute mail, the accuracy of our mailing records, and the elimination of unnecessary expense for postage and clerical work:

Bradford, A. O., Central Mex. Lt. & Pr. Co., San Luis Potosi, S. L. P., Mex.

Cromwell, P. C., Arthur Anderson & Co., 1814 Harris Trust Bldg., Chicago, Ill.

Davis, R. H., Westinghouse E. & M. Co., East Pittsburgh, Pa.

Dawson, Leonard L., 98 Looker Ave., Springfield, N. J.

Gale, R. E., 706 N. 19th St., Boise, Idaho

Herrera, R., Utah Pr. & Lt. Co., c/o Mr. Bennion, Salt Lake City, Utah

Kigar, D. F., 1403 Minnie St., Port Huron, Mich.

Lieb, Adolph W., N. Y. Edison Co., 393 7th Ave., New York, N. Y.

Mahnke, E. Chris, 1400 E. 53rd St., Chicago, Ill.

Prehn, Victor N., 940 Broad St., Newark, N. J.

Sherwood, W. E., Kew Gardens, 2700 Que St. N. W., Washington, D. C.

Sliney, David, 11 Orchard St., Cranford, N. J.

Vav Wyck, P. V. R., Summit, N. J.

Vreeland, F. P., 110 E. 176th St., New York, N. Y.

Williams, Clifton S., Research Lab., Westinghouse E. & M. Co., East Pittsburgh, Pa.

Local Meetings

New York Power Group to Meet Next in Newark

The Power Group of the Institute's New York Section will hold its next meeting in the Public Service Auditorium, 80 Park Place, Newark, New Jersey, the evening of Tuesday, February 17th, at 7:30 o'clock, with R. E. Powers of the Westinghouse Electric & Manufacturing Company as the speaker.

Mr. Powers takes for his subject "High-Speed Relaying and Switching," and will devote his time principally to showing how the margin of stability can be increased by increasing the speed of fault removal, as well as by speeding up the action of relays and circuit breakers. A general discussion in which all present should freely participate will follow Mr. Power's talk.

The nomination of Power Group officers for 1931-32 also will be considered at this meeting.

◆

Color in the Work World

On the evening of Tuesday, February 10th, the New York Section jointly with the A. S. M. E., the New York Electrical Society, and the Museum of Science and Industry, will hold a meeting on "Color in the Work World."

Chiefly, this will be a demonstration lecture by Doctor M. Luckiesh, director of the lighting research laboratory of the General Electric Company. Doctor Luckiesh, who has been making an exhaustive study of color and its effects upon the various processes of industry and occupational surroundings, is ably prepared to present his conclusions in a particularly interesting manner.

The meeting will be held in the auditorium of the Engineering Societies Building, 33 West 39th Street, New York, at 8:15 o'clock; because of the popular nature of the topic of the evening, admission will be by ticket only, but reservation forms will accompany the regular meeting notices sent out to the membership.

Future Section Meetings

Cleveland

February 19, 1931—Recent Progress in Communication Technology. Speaker from the Bell Telephone Laboratories, Inc., to be announced later.

March 19, 1931—Industrial Applications of Vacuum Tubes and Photo-Electric Cells, by E. L. Manning, General Electric Research Laboratories, Schenectady, N. Y.

Detroit-Ann Arbor

February 17, 1931—Detroit Toll Board, by E. C. Balch, Michigan Bell Telephone Co. Meeting at Michigan Bell Telephone Auditorium.

March 17, 1931—The Sound of a Shadow, by J. B. Taylor, General Electric Co.

Niagara Frontier

February 16, 1931—Air Circuit Breakers, by Mr. Gunion, I. T. E. Co.

March 20, 1931—Subject and speaker to be announced later.

Seattle

February 17, 1931—Operating Problems of Trunk Line Electrification, by J. Hawe, Electrical Engineer, Great Northern Railway.

March 17, 1931—Annual joint meeting of the Founders' Societies with program in charge of the American Society of Civil Engineers.

Sharon

February 3, 1931—Audible Light, by John B. Taylor, General Electric Co.

Spokane

March 27, 1931—Program by local members as follows: Service and Services, by G. S. Covey; Standard Meter Equipment, by J. G. Finley; Relay Application to Feeder Protection, by C. F. Norberg.

Past Section Meetings

Akron

Power Transformer Design and Tap Changing Under Load, by L. C. Nichols, Allis-Chalmers Mfg. Co. Film—"The Story of Bakelite Resinoid" presented. December 11. Attendance 70.

Baltimore

Recent Engineering Projects by the Bureau of Mechanical Service, by Warren Viessman, Mechanical-Electrical Engineer, City of Baltimore. Illustrated with views of the city's engineering developments in street lighting, airport illumination, power conduits owned by the city, city incineration, and power installations in various city buildings.

Water Works Pumpage—The Vernon Pumping Station, by Leon Small, Superintendent Engineering Division, City of Baltimore. Joint meeting with the A. S. M. E., A. S. C. E., and Baltimore Engineers Club. December 12. Attendance 58.

Boston

Recent International Understandings in Electrical Engineering and Radio, by Dr. A. E. Kennelly, Harvard University. December 9. Attendance 75.

Columbus

Chain Broadcasting and Teletype Operation, by J. T. Jenkins, American Tel. & Tel. Co. Accompanied by demonstrations of some apparatus used in teletype work. December 5. Attendance 65.

The Threshold of a New Era in Lighting, by T. P. Brown, Edison Lamp Works. Illustrated. January 9. Attendance 25.

Connecticut

High-Pressure Steam, by I. E. Moultrop, Edison Electric Illuminating Co. of Boston, and Vice-President District No. 1, A. I. E. E.;

Operating Results of the Mercury Turbine, by T. H. Soren, Hartford Electric Light Co. Meeting held at Hartford Electric Light Co., preceded by dinner at the City Club. December 15. Attendance 95.

Dallas

Meeting held under the auspices of the Student Branch at Southern Methodist University, at which the following papers were presented by Students:

Demonstration of Short-Wave Broadcasting, by D. J. Tucker;

Thermocouples, by R. L. Allen, Jr.;

Experiments with the Transformer, by Carlos Burnet. November 17. Attendance 75.

Annual Dance. December 15. Attendance 140.

Denver

The All-American Canal and the Problems of the Salton Basin, by M. M. McIntire, Imperial Irrigation District, Imperial, Calif. Illustrated with lantern slides. Dinner preceded the meeting. December 12. Attendance 32.

Detroit-Ann Arbor

Patents and Inventions, by George N. Willitts, General Motors Corporation, and Secretary Michigan Patent Law Association. Mr. Willitts pointed out the difficulties in the present patent procedure and outlined the reform in this system which the Michigan Patent Law Association has gone on record as favoring. Joint meeting with the Detroit Engineering Society. December 12. Attendance 125.

Fort Wayne

Transient Phenomena in Small Electromagnets, by H. H. Clayton, General Electric Co. Illustrated with slides.

Luminous Tubes and Transformers, by C. W. Kronmiller, General Electric Co. Considerable discussion followed. December 18. Attendance 70.

Houston

Banquet at which the members of the Section were guests of the International

Creosoting and Construction Co. Moving pictures were shown of modern methods used in the wood preserving industry. E. E. Boehne and Mr. Myers, both of the above company, explained various treatments and answered questions. December 16. Attendance 55.

Ithaca

Twentieth Century Developments in Our Knowledge of Matter and Energy, by Professor F. K. Richtmyer, Cornell University. December 12. Attendance 200.

Kansas City

Some Construction Details in an Industrial Power Plant, by C. O. Boynton, Standard Oil Co.;

Some Mechanical Engineering Problems in a Modern Oil Refinery, by W. L. Mathews, Standard Oil Co.;

Economic Design of Intercity Communication Facilities, by J. F. Burwick, Southwestern Bell Telephone Co.;

Intercity Communication Plant Construction, by J. H. Schweitzer, Southwestern Bell Telephone Co. Joint meeting with the University of Kansas Branches of A. I. E. E. and A. S. M. E. Buffet luncheon served at the close of the meeting. December 4. Attendance 180.

Lehigh Valley

Power Supply for Single-Phase Railroad Electrification, by R. T. Earle, Westinghouse Electric & Mfg. Co. C. L. Doud, Reading Railroad Co., outlined their activities in electrification in Philadelphia, and on some of their main trunk lines. Harvey Pierce, Stewart, James & Cook Co., who spent considerable time in Russia developing the coal fields, made a few remarks. Film—'Dynamic America," presented by E. M. Johnson, Westinghouse Electric & Mfg. Co. Meeting held at Pottsville. November 14. Attendance 73.

Recent Developments in the Art of Communication, by R. B. Parker, American Telephone & Telegraph Co. Illustrated with slides and an actual demonstration of the teletype. Film—"Transatlantic Radio Telephone Service." Joint meeting with the Student Branch at Lehigh University. December 5. Attendance 225.

Los Angeles

Sound Rays as Extremals, by Professor H. Bateman, California Institute of Technology. Discussion followed. December 15. Attendance 22.

Louisville

The Romance of Electric Cooking, by K. L. Aleshire, Westinghouse Electric & Mfg. Co. Electric ranges, electric refrigerators, and other appliances were demonstrated. Refreshments served. December 15. Attendance 40.

Madison

The Application of Automatic Control to Motor-Driven Machinery, by P. B. Harwood, Cutler-Hammer, Inc. Illustrated with slides. Refreshments served. November 19. Attendance 22.

Memphis

Lightning and Lightning Arresters, by H. T. Montgomery, General Electric Co. A motion picture was shown illustrating the construction of power transformers at the General Electric Works. December 9. Attendance 35.

Minnesota

Amusing Incidents of My Trip to Europe, by Milton Firestone, Attorney of St. Paul. Dinner preceded the meeting. December 17. Attendance 32.

Niagara Frontier

Armor-Clad Switchgear, by H. V. Nye, Allis-Chalmers Mfg. Co., illustrated. R. L. Melton, The Carborundum Company, gave a talk on the manufacture of abrasives, preceding the showing of the four reel film "The Jewels of Industry." An informal dinner in honor of the speakers was held at the Hotel Niagara. December 19. Attendance 85.

Oklahoma City

Protection of Power Transmission Equipment from Lightning, by Professor C. T. Almquist, University of Oklahoma.

Protection of Telephone Equipment from Lightning, by R. L. Jones, Southwestern Bell Telephone Co. General discussion of both talks followed. December 29. Attendance 59.

Philadelphia

Innovations in Remote Metering, by Alan S. Fitzgerald, Radio-Victor Corp. December 8. Attendance 150.

Problems in the Design of Large Turbo Alternators, by S. H. Mortensen, Allis-Chalmers Mfg. Co. Illustrated with slides which not only showed the steps in the manufacture of the various parts, but compared the European design with American practise. January 5. Attendance 105.

Pittsburgh

Proper Voltage and Lighting Service, by G. S. Merrill, General Electric Co.;

Artificial Sunlight, by M. Luckiesh, General Electric Co. Film—"Dynamic America" presented. Joint meeting with the Engineers' Society of Western Pennsylvania. December 9. Attendance 282.

Pittsfield

Telegraphy—A New Art with an Old Name, by J. H. Bell, Bell Telephone Laboratories, Inc. Illustrated with slides and curves. Dinner preceded the meeting. December 16. Attendance 175.

Rochester

Illumination, by Alvin L. Powell, General Electric Company. Illustrated with colored slides of modern uses of lighting. December 11. Attendance 186.

St. Louis

Some Recent Research Developments, by E. L. Manning, General Electric Co. C. B. Fall, Chairman, spoke of the legislation now under consideration for the licensing of engineers in Missouri, and appointed a committee to represent the interests of the Section. December 19. Attendance 95.

San Antonio

Film and descriptive talk on Fort Worth to Cisco Underground Toll Cable, by B. O. Timberlake, Southwestern Bell Telephone Co.;

Film and descriptive talk on Step by Step Machine Switching, by L. R. Norton, Southwestern Bell Telephone Co. Film—"Voices Across the Seas." December 15. Attendance 76.

Schenectady

Automotive Design, by John J Caton, Chrysler Motor Corporation. Discussion followed. November 21. Attendance 200.

Electricity—Past, Present, and Future, by C. M. Ripley, General Electric Co. Film—"Tipping the Chute—a Caron Obelisk." December 5. Attendance 250.

Seattle

A Resumé of Recent Developments in Predetermination of System Performance, by Dean H. V. Carpenter, State College of Washington. Discussion followed. December 23. Attendance 40.

Sharon

Split-Second Phenomena in Electrical Engineering, by Dr. Joseph Slepian, Westinghouse Electric & Mfg. Co., assisted by Dr. Phillips Thomas of the same company. Illustrated with slides and demonstrations, including a 250-kv. lightning generator, insulator strings, and auto valve arrester. Film showing equipment and operation of the Wildwood Mine of the Butler Consolidated Coal Company was supplemented by a description by Mr. Vance, Chief Engineer of that company. January 6. Attendance 140.

Springfield

The Marvels of Sound Transmission, by Sergius P. Grace, Assistant Vice-president, Bell Telephone Laboratories, Inc. Joint meeting with the Engineering Society of Western Massachusetts and the Springfield Chamber of Commerce. Dinner in honor of the speaker was given at the Colony Club. December 12-13. Attendance 9,000.

Toledo

Zig-Zag Transformers, by Alois Hoefle, Toledo Edison Co., illustrated with sketches and diagrams.

Economic Advantages of Electric Heat for Heat-Treating Processes, by Wirt S. Scott, Westinghouse Elec. & Mfg. Co., illustrated with lantern slides. December 19. Attendance 80.

Toronto

Changing Views of the Nature of Matter, by Dr. Saul Dushman, General Electric Co. Joint meeting with the Toronto Chemical Association. December 12. Attendance 300.

Hydrogen Cooling of Electrical Machinery, by C. J. Fechheimer, Westinghouse Electric & Mfg. Co., illustrated with slides. General discussion followed. January 9. Attendance 102.

Urban

Research Laboratory in a Large Manufacturing Company, by H. D. Sanborn, General Electric Co. Illustrated with lantern slides showing some of the wide variety of subjects undertaken in a research laboratory. December 19. Attendance 75.

Utah

Automatic Block Signals, by B. W. Molis, Denver & Rio Grande Western Railroad Co. Mr. Molis gave a description of the common forms of train control and signal arrangements, and had some apparatus for demonstration. Informal dinner preceded the meeting. December 8. Attendance 41.

Vancouver

Manufacture and Application of Vacuum Tubes, by G. W. Sweney, Neon Products of Western Canada Ltd. Lantern slides and films were shown illustrating the manufacture, installation, and application of neon tubes. November 17. Attendance 57.

Photoelectric Cells—Their Construction, Selection and Application, by Frank Sawford, Consulting Mechanical and Electrical Engineer. Charts were displayed and smoke-density metering equipment designed and patented by Mr. Sawford was set up for demonstration purposes. December 8. Attendance 53.

An Outline of Modern Automatic Telephone Practise, by R. S. Bowland, Independent Sales & Engineering Co. Illustrated with slides, and a demonstration, consisting of two telephones with their dials, switching equipment, and battery, was set up and operated. January 5. Attendance 52.

Washington

The Electrification of the Pennsylvania Railroad, by H. C. Griffith, Pennsylvania Railroad Co. Illustrated with slides showing various types of locomotives, overhead construction, and equipment used in construction work. Dinner in honor of the speaker preceded the meeting. December 9. Attendance 162.

Worcester

The Marvels of Sound Transmission, by Sergius P. Grace, Assistant Vice-president, Bell Telephone Laboratories, Inc. Meeting held under the auspices of the Worcester Engineering Society. December 17-18. Attendance 3500.

Insulated Wires and Cables for Power Circuits, by E. W. Davis, Simplex Wire & Cable Co. January 7. Attendance 35.

Past Branch Meetings

University of Akron

A History of Telephony, by Harold Schroeder, Branch Secretary. December 19. Attendance 18.

Alabama Polytechnic Institute

Steam Electric Power Plant, by L. O. Swint, Student;

Levee Construction Along the Mississippi River, by Charles Perry, Student;

Dirigible Construction, by E. C. Austin, Student. October 2. Attendance 36.

The Process of Manufacturing One Piece Wheel and Axle for Railroad Cars, by K. R. Clark, Student;

Testing Wattmeters, by J. M. Johnson, Student. October 9. Attendance 25.

Redevelopment of Hydroelectric Plants, by T. N. Pyke, Student;

Electricity's Part in Copper Mining, by G. A. Beavers, Student;

Experience Working with an Engineering Party, by H. L. Beck, Student. October 23. Attendance 16.

Smoker and entertainment. October 30. Attendance 76.

Molding Cast Iron Pipe by the Centrifugal Method, by S. E. Garrett, Student. November 6. Attendance 15.

R. A. Mann, representative of the Branch, outlined the activities of the District meeting held in Louisville. G. A. Beavers gave an account of the Eta Kappa Nu meeting held in Ames, Iowa. December 4. Attendance 17.

Election of officers as follows: R. A. Mann, Chairman; C. L. Perry, Vice-Chairman; L. B. Crouch, Secretary-Treasurer; K. R. Clark, Reporter. December 11. Attendance 12.

University of Alabama

Copper-Weld Wire, by W. B. McClure, Student;

Lightning Investigation on 110 Kv. Line, by Harold B. Hendrix, Branch Secretary. Walter H. Croft, Chairman, gave a report of his trip to the District meeting held in Louisville. December 8. Attendance 16.

University of Arizona

A Trip Through the East, by A. W. Fraps, Student. October 24. Attendance 10.

Industrial Use of Vacuum Tubes, by C. J. Sabin, Student. October 31. Attendance 8.

Television, by H. P. McGovern, Student. C. J. Sabin appointed Chairman of Electrical Show. November 7. Attendance 8.

A Brief Review of the Development of Power Plants, by Max Pooler, Tucson Gas, Electric Light and Power Company. Banquet meeting. November 19. Attendance 25.

Talkies, by J. C. Hall, Student. November 21. Attendance 9.

Business meeting. December 5. Attendance 10.

Circuit Breakers, by W. T. Brinton, Student;

Vacuum Tube Circuit Breaker, by Professor J. C. Clark, Counselor. December 12. Attendance 10.

Thermodynamic Regulator, by R. Manzo, Student. December 19. Attendance 10.

University of Arkansas

Film—"The Single Ridge." November 19. Attendance 22.

Grid-Glow Tube and Photoelectric Cell, by Wylie Head, Branch Secretary. Demonstrated. December 3. Attendance 23.

Armour Institute of Technology

Smoker. December 10. Attendance 87.

Industrial Electric Heating, by L. J. Ericsson, General Electric Co. Illustrated with motion pictures. December 15. Attendance 40.

Polytechnic Institute of Brooklyn

Substation Maintenance Practise, by Rodney Brabson, Student;

Electrolysis of Subway Cables in Telephone Work, by Leon K. Danner, Student;

High-Frequency Currents and Short Radio Waves as Valuable Adjuncts to the Medical Sciences, by Ivan Block, Student. There were two prizes; first won by Ivan Block, and second by Leon K. Danner. December 12. Attendance 33.

Carnegie Institute of Technology

Commercial Problems that an Electrical Engineer is Required to Face in the Steel Industry, by William Skinkle, United States Steel Corporation, and Director of the Engineers' Society of Western Pennsylvania. Illustrated with slides. November 13. Attendance 30.

Electrical Engineering in an Electric Public Utility, by R. L. Kirk, Duquesne Light Co. December 9. Attendance 85.

Catholic University of America

The Fundamentals of Radio, by Professor T. J. MacKavanagh, Counselor. December 16. Attendance 30.

University of Cincinnati

Public Utilities and the Public, by E. D. Gilman, Director, Public Utilities of the City of Cincinnati. December 10. Attendance 26.

Colorado Agricultural College

The Public Relations with Public Utilities, by Mr. Jamison, Public Service Co. of Colorado. December 8. Attendance 16.

University of Denver

Aviation Lighting, by F. L. Woodward, Student. November 8. Attendance 18.

Film—"Beyond the Microscope." December 12. Attendance 40.

University of Detroit

The Principles of X-Rays, by C. J. Haller, General Electric X-Ray Corporation. November 24. Attendance 40.

University of Florida

A history of the A. I. E. E. and its activities was given by Professor W. S. Rodman, University of Virginia, and Vice-President District No. 4, A. I. E. E. Professor Rodman also gave an address, Some Aspects of the Scientific Work of Thomas Jefferson, through the University of Florida radio station, WRUF. December 17. Attendance 63.

Arc Welding, by F. J. Nelson, Student. Discussion of Branch affairs. January 12. Attendance 20.

University of Iowa

Films—"The Wizardry of Wireless," and "Liquid Air." December 17. Attendance 40.

The Part of Electricity in Open-Cut Copper Mining, by Mr. Hammond, Student;

The Oscillograph, by Mr. Jenkins, Student. January 7. Attendance 41.

University of Kansas

The Design and Testing of Motion Picture Screens for Sound Picture Work, by Lester Perry, Student;

The Applications of Photoelectric Cells, by Louis Farber, Student. A three-reel film on transmission cable insulation was shown. December 18. Attendance 55.

Lehigh University

Recent Developments in the Art of Communication, by R. D. Porter, American Tel. & Tel. Co. Joint meeting with the Lehigh Valley Section. December 5. Attendance 250.

University of Maine

Election of officers as follows: Monroe E. Moon, President; S. L. Scheffer, Vice-president; L. O. Spencer, Secretary; H. G. Marshall, Treasurer. September 25. Attendance 15.

Talks by D. B. Henderson and L. O. Spencer, Students, on their summer experiences. Professor W. E. Barrows, Jr., Counselor, outlined the N. E. L. A. convention, and described the progress and future possibilities in the field of illumination engineering. October 30. Attendance 20.

Smoker and entertainment. Demonstrations of high-frequency phenomena and Tesla effects. November 20. Attendance 250.

Railway Electrification, by S. L. Scheffer, Student. Professor W. E. Barrows, Jr., Counselor, gave a demonstration of some new illumination equipment received from the General Electric Co. December 11. Attendance 16.

Marquette University

Films—"Blasting the Water Highways of America," and "Hydroelectric Power Production in the New South." December 4. Attendance 22.

Massachusetts Institute of Technology

The Opportunities for the Graduate who Enters Electrical Manufacturing, by C. E. Eveleth, Vice-President, General Electric Co. Dinner preceded the meeting. January 7. Attendance 300.

Michigan College of Mining and Technology

Substations and Their Uses, by E. E. Chilberg, General Electric Co.;

Transformers, by I. E. Devlin, General Electric Co. Illustrated with educational films. December 9. Attendance 31.

University of Michigan

Materials in the Magnetic Circuits of Communication Apparatus, by Dr. Remmers, Western Electric Co. Illustrated with slides showing the characteristics, manufacturing processes, and uses of many magnetic materials. An explanation of the various branches of the Bell System was given by J. T. Schaefer, Michigan Bell Telephone Co. R. A. Price, Western Electric Co., made a few remarks. December 17. Attendance 55.

School of Engineering of Milwaukee

The Story of Electrical Inspection, by Wm. Haig, Head of Electrical Inspection Department of the City of Milwaukee, assisted by Mr. Crickie. December 3. Attendance 41.

Mississippi A. & M. College

J. M. Leigh, Chairman, gave an outline of the various activities at the District Meeting held in Louisville. December 5. Attendance 31.

University of Missouri

Rectox Rectifiers, by Mr. Vincill, Student. January 7. Attendance 23.

Montana State College

Vacuum Tubes, by B. L. Snoddy, General Electric Co. December 4. Attendance 126.

Developing Power from Sea Water, taken from the *Electrical World*, presented by A. J. Hill, Student;

Successful Trolley Bus Operation Demands Suitable Overhead, taken from *Railway Journal*, presented by A. T. Keene, Student;

The Breathing Battery, taken from *Radio World*, presented by H. T. Lambdin Student;

Night Football, taken from *Electrical World*, presented by R. MacDonald, Student;

A New Weather Broadcasting Station in Butte, by Henry Nervobig, Student. December 11. Attendance 130.

University of Nebraska

Professor F. W. Norris, Counselor, gave an illustrated talk, describing the action of the telephone typewriter used by the Bell System. December 17. Attendance 14.

Newark College of Engineering

Double-Wound Generators, by F. W. Gay, Public Service Production Co. December 15. Attendance 28.

Electrical Horology, by W. R. Acker, Chairman. Demonstrated. January 5. Attendance 29.

University of New Mexico

The Vacuum Tube, by S. M. Pelatowski, Student;

The Life of C. P. Steinmetz, by R. Harris, Student. December 17. Attendance 9.

North Carolina State College

Some Aspects of the Scientific Work of Thomas Jefferson, by Professor W. S. Rodman, University of Virginia, and Vice-president District No. 4, A. I. E. E. Banquet in honor of new members preceded the meeting. December 10. Attendance 60.

Film—"From Coal to Electricity." D. P. Melton, Student, explained the proposed exhibits for the Engineers Fair. January 6. Attendance 40.

University of North Carolina

The Manufacture of Porcelain Insulators, by E. W. Winkler, Instructor;

Pulverized Fuel, by E. R. Davis, Student. November 20. Attendance 41.

Some Aspects of the Scientific Work of Thomas Jefferson, by Professor W. S. Rodman, University of Virginia, and Vice-president District No. 4, A. I. E. E. December 11. Attendance 80.

Northeastern University

Engineering Ethics, by H. C. Hamilton, Edison Electric Illuminating Co. of Boston. Refreshments were served. December 2. Attendance 49.

University of Notre Dame

Structural Arc Welding, by W. M. Brady, General Electric Co., illustrated with motion pictures and slides.

The Life of Volta, by P. A. Darmody, Student;

The Development of the Incandescent Lamp, by J. B. Strebinger, Student. Patrick Murray, Student, presented the regular engineering news digest. December 9. Attendance 70.

Ohio University

The Photo-Flash Bulb, by William Miller, Student. Film—"Liquid Air." December 15. Attendance 14.

Oklahoma A. & M. College

Two films—"Induction Voltage Regulators," and "The Vacuum Tube Synchronizing Equipment." December 4. Attendance 47.

Relays, by Paul Foster, Student. Illustrated with slides. December 18. Attendance 12.

Oregon State College

Carrier-Current Telephony, by W. R. Deardorff, Pacific Tel. & Tel. Co. W. A. Kleist, of the same company, supplemented Mr. Deardorff's talk. December 9. Attendance 25.

Pratt Institut

Transmission of Pictures by Wire, by Mr. O'Nasch, New York Telephone Co. Illustrated with slides. December 18. Attendance 180.

Princeton University

Magnetic Potentiometers, by R. M. Kime, Student;

The Generation of Steam, by Ernest E. George, Student. December 11. Attendance 10.

Purdue University

The Storage Battery—A Box Full of Problems, by R. J. Kryter, Prest-O-Lite Storage Battery Co. December 9. Attendance 35.

Rensselaer Polytechnic Institute

New General Electric Permanent Magnet Oscillographs, by Claude Hathaway, General Electric Co. December 9. Attendance 130.

University of South Carolina

What is Expected of the College Graduate, by R. E. Brooks, Student;

The Development of Arizona, by W. T. Thomas, Student. December 8. Attendance 40.

Some Aspects of the Scientific Work of Thomas Jefferson, by Professor W. S. Rodman, University of Virginia, and Vice-President District No. 4, A. I. E. E. December 15. Attendance 125.

Election of officers as follows: L. E. Rankin, Chairman; C. H. Bryan, Vice-chairman; W. Dickerson, Secretary-Treasurer. January 5. Attendance 14.

South Dakota School of Mines

Annual Frolic with entertainment and luncheon. December 16. Attendance 116.

University of Southern California

High-Tension Line Construction, by Clayton M. Allen, Bureau of Power & Light. December 10. Attendance 29.

Southern Methodist University

Ultra Short-Wave Transmission, by J. D. Tucker, Student. December 9. Attendance 21.

Stanford University

Address by Dean Dexter S. Kimball of Cornell University. Joint meeting with the A. S. M. E. Branch. December 9. Attendance 50.

Stevens Institute of Technology

Election of officers as follows: George J. Costello, Chairman; Edmund Starzec, Secretary. General discussion of Branch activities. December 11. Attendance 9.

Film—"The Single Ridge." December 19. Attendance 17.

The Life of Michael Faraday, by Paul H. Beier, Student. January 8. Attendance 30.

Swarthmore College

Discussion of plans for the coming A. I. E. E. Student Convention to be held at Swarthmore College. January 7. Attendance 11.

Syracuse University

The Radio Beacon, by Alex Paterson, Student;

Carrier Current in Telephony, by Chester Grant, Student. December 12. Attendance 25.

The Photoelectric Cell, by Oliver Bigsby, Student;

Television, by Stewart Darrow, Student. December 19. Attendance 25.

Sperry Gyroscopic Stabilizers, by Stanley Scerbinski, Student;

Non-Resonating Transformers, by George Cowell, Student. January 9. Attendance 25.

Texas A. & M. College

Electric Refrigeration, by George Cushman, Student;

Gas Refrigeration, by R. L. Allen, Student. November 24. Attendance 50.

Film—"Oil Circuit Breakers." December 8. Attendance 50.

University of Texas

General discussion and plans made for a banquet meeting. September 23. Attendance 20.

Why I Became a Member of the A. I. E. E., by C. A. Glover, Student. Dinner preceded the meeting. September 29. Attendance 80.

Short talks by Professor J. A. Correll, Counselor, and Lyle Burnham, Student. October 15. Attendance 41.

History of Hydroelectric Development at Austin, Texas, by T. E. Cole, Student. December 11. Attendance 17.

University of Vermont

Properties of Perminvar and Permalloy, by Professor R. O. Buchanan. Illustrated. December 16. Attendance 24.

University of Washington

The Applications of the Photoelectric Cell, by J. Mackay, Student. December 4. Attendance 20.

The Rock Island Development, by Mr. DeMuth, Stone & Webster Engg. Corp. November 20. Attendance 74.

Washington University

Economic Aspects of the Generation of Power, by Professor Roy S. Glasgow. December 11. Attendance 21.

Engineering Literature

New Books

In the Societies Library

AMONG the new books received at the Engineering Societies Library, New York, during December are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

Sound Waves and Their Uses. By Alexander Wood. Lond. & Glasgow, Blackie & Son, 1930. 152 pp., illus., diagrs., tables, 9 x 6 in., cloth. 7/6.——These six lectures delivered at the Royal Institution give a remarkably readable, well illustrated account of modern development in acoustics. Methods of signaling in air and water, noises, the analysis of sounds, the ear, and the recording and reproduction of sound are discussed. The book is suited to the general reader without previous training, but references are included for those who wish further information.

Acoustics; a Text on Theory and Applications. By George Walter Stewart and Robert Bruce Lindsay. N. Y., D. Van Nostrand Co., 1930. 358 pp., diagrs., tables, 9 x 6 in., cloth. $5.00.——The increasing use of acoustical apparatus has created a need for better understanding of the theory of acoustics. The present book aims to meet the need by providing a clear exposition of the theory, in which modern applications are kept to the fore. The book is intended to provide the equipment necessary for attacking mathematically the problems that confront the designer of telephone equipment, the architect and other investigators.

A Century of Wood Preserving. Edited by Sir Harold Boulton. London, Philip Allan & Co., 1930. 150 pp., plates, 9 x 6 in., cloth. 8/6.——A collection of papers upon wood preservation, especially by creosoting, which form an account of the development of the art during the hundred years that have passed since John Bethell became interested in the subject. Bethell's patent is given in an appendix, and there is a long list of references on wood preservation.

Diesel Power Plant Handbook (formerly the Oil Engine Power Plant Handbook). 6th edition. By Julius Kuttner. N. Y., Diesel Power, 1930. 280 pp., illus., 11 x 8 in., fabrikoid, $5.00. ——The text of this edition consists of a practical course on the operation and maintenance of Diesel engines, which should meet the ordinary requirements of the engine room. In addition the book contains condensed descriptions of the Diesel engine manufacturers of the United States.

Electric Circuit Analysis. By Michel G. Malti. N. Y., John Wiley & Sons, 1930. 389 pp., diagrs., tables, 9 x 6 in., cloth. $4.50.——In this book the author first discusses complex numbers, vectors and the theory of sine functions. The electric units and their dimensions are then studied, after which the characteristics of an electric circuit are explained. The steady and transient phenomena in an electric circuit are then discussed at length. The book represents the course in circuit analysis given at Cornell University.

Electrical Power Transmission and Interconnection. By C. Dannatt and J. W. Dalgliesh. N. Y., Isaac Pitman & Sons, 1930. 424 pp., diagrs., tables, 9 x 6 in., cloth. $7.50.——The bulk transmission of electrical energy has become a major engineering problem, presenting new and wide issues, upon which much scattered literature exists. To obviate the laborious search for this, the authors have attempted to provide a complete introduction to the electrical aspects of power transmission and interconnection. Overhead and underground lines, corona, network theory, line calculations, power and stability, interference, neutrals, and transient voltage phenomena are among the topics treated.

Electricity and Magnetism. By Charles A. Culver. N. Y., Macmillan Co., 1930. 383 pp., illus., diagrs., tables, 9 x 6 in., cloth. $3.25.——Intended to give students of the liberal arts a reasonably thorough understanding of the fundamental principles of electricity and magnetism and of their commercial applications.

Flights from Chaos. By Harlow Shapley. N. Y., Whittlesey House; McGraw-Hill Book Co., 1930. 168 pp., 9 x 6 in., cloth. $2.50.——Dr. Shapley here presents his conception of order in the apparent chaos of the universe, and develops a general, complete classification of all material systems, from electrons to the galaxy of galaxies, into a series of classes of ever increasing size and mass. The book is based upon a series of lectures and is addressed to the lay reader.

Hydraulics for Engineers and Engineering Students. By Frederick Charles Lea. 5th edition. N. Y., Longmans, Green & Co., 1930. 775 pp., illus., diagrs., tables, 9 x 7 in., fabrikoid. $7.50.——The new edition of this well-known text-book apparently has been entirely reset, and in the process the accumulated appendices have been incorporated in the text. A considerable amount of material upon recent researches and developments and a chapter on dynamic similarity have been added.

The book offers a clear, practical exposition of the fundamentals of hydraulics, with illustrations of their applications to water wheels, pumps and hydraulic machines, and to the measurement of the flow of water.

Manuale Pratico di Telegrafia Sottomarina. By Italo de Guili. Milano, Ulrico Hoepli, 1931. 384 pp., illus., diagrs., tables, 6 x 4 in., cloth. 30 lire.——A textbook on submarine cable practise for students and operators. The construction of lines and apparatus is described in detail. Theory is reduced to the minimum.

Patent Rights for Scientific Discoveries. By C. J. Hamson. Indianapolis, Bobbs-Merrill Co., 1930. 286 pp., 9 x 6 in., fabrikoid. $5.00.——This monograph, which received the Charles C. Linthicum Foundation prize in 1929, discusses the important new legal idea of "scientific property." The author reviews the historical development of the idea and past attempts to protect the rights of discoverers of scientific facts, and discusses the problems that arise in formulating a law to protect discoverers. The draft of a proposed statute is given and the objections to it discussed.

Starkstromtechnik, vol. 2. Edited by E. V. Rziha and J. Seidener. 7th edition. Berlin, Wilhelm Ernst & Sohn, 1931. 1034 pp., illus., diagrs., tables, 7 x 5 in., cloth. 37.-r. m.——Corresponds in form and character to American "handbooks" of electrical engineering. The present (second) volume covers the production and transmission of electric energy, and its use in mining and agriculture, for hoisting and rolling metals and in factories. The new edition has been thoroughly revised by a number of specialists.

A Study of the Induction Motor. By F. T. Chapman. N. Y., John Wiley & Sons, 1930. 289 pp., illus., diagrs., 9 x 6 in., cloth. $5.50.——Dr. Chapman develops the theory of the induction motor and discusses the characteristics of the various types, using only simple algebra and geometry in his argument.

Theorie der Wechselströme. By Alfred Fraenckel. 3rd edition. Berlin, Julius Springer, 1930. 260 pp., illus., diagrs., 10 x 7 in., bound. 21,50 r. m.——A concise text-book for students of electrical engineering, intended to present the knowledge of alternating-current theory needed by the practical engineer, and to train him in the graphic and analytic methods used to investigate the phenomena of a-c. circuits.

Artificial Sunlight; combining radiation for health with light for vision. By M. Luckiesh. N. Y., D. Van Nostrand

ENGINEERING SOCIETIES LIBRARY

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

Co., 1930. 254 pp., illus., diagrs., tables, 9 x 6 in., cloth. $3.75. Dr. Luckiesh discusses the need for artificial sunlight, our methods of producing and controlling it, and the fields in which it may be applied. Much physical and biological information is given upon radiant energy, the advantages of the "sunlight lamp" are explained and compared with those of other sources of ultraviolet rays. Practical methods of dual-purpose lighting are discussed.

BROWN'S DIRECTORY OF AMERICAN GAS COMPANIES AND GAS ENGINEERING AND APPLIANCE CATALOGUE. 1930. N. Y., Robbins Publishing Co., 1930. 284-369 pp., illus., 12 x 9 in., cloth. $15.00.——As in previous editions, we find here the gas statistics of the companies supplying manufactured and natural gas in North America and of the holding and operating companies in the continent. The members of public service commissions are also listed, and the officers and members of gas associations. In addition the volume contains condensed catalogs of manufacturers of gas equipment and supplies. The statistics are revised to date and include those ordinarily wanted.

◆

Selected Items *From*

Engineering Index Service

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 1,800 technical periodicals are given in the following columns.

All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page or make translations of foreign articles at cost.

Arcs

ALTERNATING CURRENT. Supply of Electric Arcs with Alternating Current (Considérations générales sur l'alimentation des arcs a courant alternatif), A. de Stavraky. *Revue d'Electricité et de Mécanique (Paris)*, no. 13, Sept.-Oct. 1930, pp. 10-11, 3 figs. Equipment derived from P. Boucherot's and J. Berthenod's suggestions is reviewed; remedies for instability and for improvement of power factor are suggested; the theoretical study of these apparatus are given in same number of journal.

Brakes

ELECTRIC. New Methods of Approach for Explanation and for Improving Results in Braking of Street Railroad Cars (Neue Wege zur Klaerung der Vorgaenge und zur Verbesserung der Ergebnisse bei der Bremsung von Strassenbahnwagen), R. Boehm. *Verkehrstechnik (Berlin)*, no. 47, Nov. 21, 1930, pp. 625-630, 18 figs. Present electric braking equipment of Nuernberg-Fuerth line and results obtained; relation between maximum and average braking retardation; influence of slipping and sanding, cinematographic-oscillographic method of research; improved braking results.

Cables

ALUMINUM. Aluminum in Armoured Electric Cables (L'aluminium dans les cables electriques armes). *Radioélectricité et QST Francais (Paris)*, vol. 11, no. 81, Dec. 1930, pp. 28-30, 4 figs. Composition, conductor material, insulation resistance, disruptive strength; excessive voltages and currents, laying qualities; comparison between copper and aluminum conductors from economical standpoint, armoring.

LEAD SHEATHING. Flow Characteristics of Some Lead Cable Sheath at Temperatures Above Atmospheric, O. L. Clark and C. Upthegrove. *Fuels and Steam Power (A. S. M. E. Trans.)*, vol. 52, no. 27, Sept.-Dec. 1930, pp. 249-254, 16 figs. Paper previously indexed from Advance Paper, no. 1, for mtg. June 9-12, 1930.

OIL FILLED. 75-Kv., Three-Conductor, Oil-Filled Cable, E. F. Nuezel. *Elec. World*, vol. 96, no. 24, Dec. 13, 1930, pp. 1088-1092, 16 figs. Union Gas & Electric Co. has taken step forward in oil-filled cable field with recent installation at its Columbia station; cable is first installation of 75-kv. three-conductor, shielded conductor type, oil-filled cable in this country; many features in design of cable and its accessory equipment are entirely new and original developments of General Electric Co. to meet particular requirements of installation.

SPLICING COMPOUNDS. Tentative Methods of Testing Cable Splicing and Pothead Compounds. *Am. Soc. Testing Metals.—Tentative Standards*, 1930, pp. 564-570, 2 figs. Methods cover: physical tests; dielectric strength test and coefficient of expansion.

TELEPHONE, SUBMARINE. Two-Band Communication from Helgoland to Cuxhaven and Hamburg (Zweibandsprechen von Helgoland nach Cuxhaven und Hamburg), W. Weinitschke. *Telegraphen und Fernsprech Technik (Berlin)*, vol. 19, no. 10, Oct. 1930, pp. 310-312, 6 figs. Use of 80 km. telephone telegraph cable which had become overloaded with traffic is now used for two band carrier current telephony which has brought solution and satisfactory results; measurements; curves.

Canals

ELECTRIC EQUIPMENT. The Electrical System of the Welland Ship Canal, A. L. Mudge, L. P. Rundle and F. A. Pankhurst. *Elec. News (Toronto)*, vol. 39, no. 22, Nov. 15, 1930, pp. 49-86, 63 figs. Description of power house, step-up transformer station, transmission line, substations, lock distribution system, motors and control equipment, lock operation, signals, bridges, lighting, heating, telephones, standardization, foreign cable crossings and gate lifter.

Car Lighting

Electric Train Lighting on Secondary Railroads (l'eclairage electrique des trains de chemins de fer secondaries), Vincent. *l'Industrie des Voies Ferrées et des Transports Automobiles (Paris)*, vol. 24, no. 286, Oct. 1930, pp. 278-282, 6 figs. Review of relative merits of various equipment and makes with particular regard to systems using battery and generator driven from axle, including Systeme E. V. R., Systeme Brown-Boveri.

Ceramic Kilns

ELECTRIC. Electric Heat for Ceramic Kilns, J. T. Jans. *Ceramic Age*, vol. 16, no. 6, Dec. 1930, pp. 326-327 and 330, 1 fig. Characteristics of high and low temperature kilns. Paper presented before New Jersey Clay Workers Assn., Oct. 1930.

Circuit Breakers

OIL. Oil Circuit Breaker Design. *Elec. Times (Lond.)*, vol. 78, no. 2039, Nov. 20, 1930, pp. 885-887, 5 figs. Phenomena of arc rupturing with special reference to the R type oil circuit breaker of Ferguson, Pailin, Ltd.

SPEED CHARACTERISTICS. Circuit-Breaker Duty Affected by Speed, O. L. Denault. *Elec. World*, vol. 96, no. 20, Nov. 15, 1930, pp. 913-915, 5 figs. When circuit is opened by breaker voltage recovers; circuit characteristics determine rate of voltage recovery; delayed recovery promotes deionization, less arc length, time and energy.

Clocks

ELECTRIC. Clocks and Apparatus with Synchronous Motor, A. Rabinowitsch. *AEG Progress (Berlin)*, vol. 6, no. 12, Dec. 1930, pp. 374-378, 12 figs. Advantages of electric clocks and other control apparatus equipped with synchronous motors.

Coal Mines

ELECTRIC DRIVE. Electric Drives for Main Shaft Ventilators (Die elektrischen Antrieb fuer Hauptschachtluefter), K. Schade. *Elektrizitaet im Bergbau (Munich)*, vol. 5, no. 11, Nov. 15, 1930, pp. 205-216, 25 figs. Determination of required power and details of drive; regulatable drives; wiring diagrams of various combinations and systems; equipment described and illustrated. (To be continued.)

ELECTRIC EQUIPMENT. Power Consumption, Output, and Economy of Electric Haulage Equipment and Coal Cutters in Underground Coal Mining (Energieverbrauch, Leistung und Wirtschaftlichkeit der elektrischen Abbaufoerdereinrichtungen und Schraemmaschinen im untertaegigen Steinkohlenbergbau), E. Meyer. *Elektrizitaet im Bergbau (Munich)*, vol. 5, no. 10, Oct. 10, 1930, pp. 185-203, 16 figs. Results of measurements on equipment of various types are summarized in curves and tables.

Commutators

High Speed Commutators, B. Bonnell. *Elec. Times (Lond.)*, vol. 78, no. 2037, Nov. 6, 1930, pp. 791-792, 4 figs. Suggestions for manufacture of high-speed commutators of "V" ring construction.

Condensers

POWER FACTOR IMPROVEMENT. Electric Power Condensators for Reactive Current Compensation and their Economy in Industrial Installations (Starkstrom-Kondensatoren zur Blindstrom-Kompensation und ihr Wirtschaftlichkeit in Industrieanlagen), H. Cypra. *Elektrizitaet im Bergbau (Munich)*, vol. 5, no. 11, Nov. 15, 1930, pp. 216-219, 6 figs. Condensers are recently favored over rotating equipment because of low internal losses and simple and safe installations; features are described and equipment of AEG illustrated; internal loss curves are given in accordance with reactive load.

Conductors

Propagation of Electricity Through Conducting Wire (Propagation de l'électricité dans un fil conducteur), J. Granier. *Radioélectricité et QST Francais (Paris)*, vol. 11, no. 81, Dec. 1930, pp. 6-9, 1 fig. Theoretical mathematical analysis in which all line characteristics are considered, discussing also various practical cases as for instance, series equation showing potential distribution along line, application to submarine and underground cables, etc.

RESISTANCE. Ohmic Resistance of Copper Conductors at High Frequency (Résistance ohmique des conducteurs en cuivre en haute fréquence), M. Mathieu. *Arts et Métiers (Paris)*, vol. 83, no. 122, Nov. 1930, p. 450, 1 fig. Curve gives values of constants for conductors from 0.1 to 10 mm. at frequencies from 10 to 300,000 kilocycles.

STRENGTH. Stretch of Wire Cables (Die Dehnungsarbeit am Seilen), J. Groebl. *Elektrotechnische Zeit. (Berlin)*, vol. 51, no. 49, Dec. 4, 1930, pp. 1669-1673, 6 figs. Investigation mainly refers to wire cables used in electric transmission lines; notes on torsion as factor of stretch; number of torsions as function of tensile strength; equation of torsion curve in over proportional range; calculation of torsional stretch; normal stretch equation; calculation of fictive elasticity modulus. (To be concluded.)

Conductivity

ELECTRIC. Recent Studies of Supraconductivity (Neue Untersuchungen ueber Supraleitfaehibkeit). *Zeit. fuer die gesamte Kaelte-Industrie (Berlin)*, vol. 37, no. 11, Nov. 9, 1930, pp. 218-220. Report on works of W. J. de Haas, E. van Aubel and T. Voogd; investigation to determine change in conductive characteristics of combination of supraconductor with non-supraconductor to alloy; reference is made to experiments in Leiden and Toronto.

Cranes

ELECTRIC. Improved Electrical Crane Equipment, B. Erenyi. *AEG Progress (Berlin)*, vol. 6, no. 12, Dec. 1930, pp. 372-373, 3 figs. Improvements described are "telegraphing" system of switching (tap control) and two-speed crane motor.

Dielectrics

ELECTRIC CONDUCTIVITY. The Conduction of Electricity in Liquid Dielectrics, D. H. Black and R. H. Nisbet. *Lond., Edinburgh, and Dublin Philosohpical Mag. and Jl. of Science (Lond.)*, vol. 10, no. 66, Nov. 1930, pp. 842-861, 11 figs. Possibility of applying theory of conduction in gases to conduction in liquid dielectrics is investigated; gas theory is considered as leading to distribution of internal resistances, and is shown to be special case of general theory advance in previous paper which attributed fall of current usually known as "absorption" to formation of internal resistances. Bibliography.

Diesel-Electric Plants

COSTS. Economics of the Use of Diesel Engines for Electric Power Generation, T. A. Burdick. *Oil and Gas Power (A. S. M. E. Trans.)*, vol. 52, no. 25, Sept.-Dec. 1930, pp. 65-74, 3 figs. Abstract of paper presented before Am. Soc. Mech. Engrs., previously indexed from Power, Sept. 16, 1930.

DESIGN. Further Refinement Characterizes Diesel Power. *Power Plant Eng.*, vol. 34, no. 24, Dec. 15, 1930, pp. 1425-1428, 3 figs. Refinement of engine construction, increase in use of auxiliary equipment, and improved plant management increase reliability of Diesel power; Diesel-plant data covering five central stations, six municipal plants, and five industrial applications; Diesel-engine data.

Electron-Theory

METALS. Some Recent Advances in the Electron Theory of Metals, R. H. Fowler. *Instn. Elec. Engrs.—Jl. (Lond.)*, vol. 68, no. 467, Nov. 1930, pp. 1469-1475, 3 figs. Nature of metal and classical theory; quantum mechanical revision; new conduction theory; thermoelectric effects; emission of electrons; magnetism and ferromagnetism; Kapitza's experiments on conductivity in strong magnetic fields.

Education

ENGINEERING. Summary of the Study of Technical Institutes, W. F. Wickenden. *Mgmt. (A. S. M. E. Trans.)*, vol. 52, no. 26, Sept.-Dec. 1930, pp. 63-69 and (discussion) 69-72. Previously indexed in Engineering Index 1929, p. 756, from Am. Soc. Mech. Engrs.—Advance Paper, for mtg. Dec. 2-9, 1929.

Broadening Effects of Engineering Education Demonstrated by Statistics, D. B. Prentice. *Mech. Eng.*, vol. 52, no. 12, Dec. 1930, pp. 1102-1103. Carnegie Foundation for Advancement of Teaching is making Elaborate study of secondary and collegiate education in Pennsylvania; important part is comprehensive examination in all fields of knowledge to measure content of students' minds; in spite of fact that more than half college course for engineers was devoted to professional subjects and many more hours to fundamental sciences, seniors possessed breadth of knowledge sufficient to score much higher in fields not their own than arts men.

Electric Circuits

Early Developments in A. C. Circuit Theory; Some Notes on the Application of Complex Methods to the Solution of A. C. Circuit Problems, G. Windred. *Lond., Edinburgh, and Dublin Philosophical Mag. and Jl. of Science (Lond.)*, vol. 10, no. 66, Nov. 1930, pp. 905-914. Neglect of theory in England is pointed out; theoretical mathematical analysis. Bibliography.

THREE-PHASE. Protection and Metering for Three-Wire Circuits, J. Auchincloss. *Power Plant Eng.*, vol. 34, no. 23, Dec. 1, 1930, pp. 1363-1366, 13 figs. Methods of locating faults in various circuits; two-phase five-wire with common protection; metering three-phase, three-wire and two-phase, four-wire power on one three element meter. (Concluded.)

Electric Discharge

NEON. Discharges in Neon, P. Johnson. *Lond., Edinburgh, and Dublin Philosophical Mag. and Jl. of Science (Lond.)*, vol. 10, no. 66, Nov. 1930, pp. 921-931, 4 figs. Following on researches which have been made at Electrical Laboratory, Oxford, on electric forces required to maintain high-frequency discharges in certain gases, author has undertaken measurement of these forces in neon.

TUBE FAILURE. A Note on the Fracture of Discharge-Tubes, R. H. Sloane. *Lond., Edinburgh, and Dublin Philosophical Mag. and Jl. Science (Lond.)*, vol. 10, no. 67, Dec. 1930, pp. 1099-1102, 1 fig. While investigating conditions of excitation near cathode of glow discharge in argon, inconvenience was experienced from frequent spontaneous failure of tubes, where discharges of only 2 milliamperes at 400 volts wire passed; apparently it is due partly to use of argon, which, as is well known, gives rise to heavy cathodic sputtering, but mainly to fact that design of tubes involved contact of cathode with walls.

Electric Furnaces

Electric Melting and Heating of Metals, W. S. Gifford. *Metal Industry (Lond.)*, vol. 37, no. 21, Nov. 21, 1930, pp. 481-484, 4 figs. Review of development and use of principal types of furnaces; Ajax Wyatt furnaces; arc furnaces; induction furnaces; high-frequency induction furnaces; refractory linings; resistance furnaces; factors controlling efficiency and operation with various metals. Paper read before mtg. of Manchester Assn. Engrs.

ANNEALING. Annealing Furnaces in the Metal Industry, Especially Modern Electric Furnace (Gluehoefen; besonders die neueren elektrischen, in der Metallindustrie), B. Schulz. *Brennstoff- und Wacrmewirtschaft (Halle)*, vol. 12, no. 17-18, Sept. 1-2, 1930, pp. 217-218, 2 figs. Electric annealing and heat-treating furnaces; equipment for heat-treating metal tubes and annealing of hoops, sheets, and wires.

HIGH FREQUENCY. Alloy Steel Melting in the Induction Furnace, O. Doerrenberg and N. Broglio. *Metallurgist (Supp. to Engineer, Lond.)*, Nov. 1930, pp. 166-167. Installation built at Ruenderoth has been in continuous day and night use, and at time of writing has been responsible for more than 1200 melts; furnace is energized by means of special generator capable of maintaining 1200 volts at frequency of 2000 cycles per sec.; tapered form of crucible has been adopted in spite of deliberate sacrifice of electrical energy implied by its use. Translated abstract of paper previously indexed from Stahl und Eisen, May 8, 1930.

Which do You Prefer?

LAST month we presented 73 of these references to current engineering literature, using large type; this month we present 115 items, using smaller type.

WHICH serves your purposes best? A PROMPT note to the Editor will be appreciated and will help to improve this reference service.

INDUCTION. Electrical Apparatus for the Coreless Induction Furnace, N. R. Stansel. *Iron and Steel Engr.*, vol. 7, no. 11, Nov. 1930, pp. 519-524, 15 figs.

Furnaces and accessories of 50 kw. and over are described in some detail; efficiency and temperature resistivity curves are given.

STEEL MAKING. High-Frequency Furnace Produces Pure Steel, K. Hohage and B. Matuschka. *Steel*, vol. 87, no. 24, Dec. 11, 1930, pp. 55-56. Type of furnace used by Schoeller-Bleckmann Steel Works, Vienna, Austria, has melting crucible made of acid refractory with coil wound around it; direction of current in coil is changed 3000 times per sec.; current is generated in separate high-frequency converter.

TRANSFORMERS. Transformers for Electric Furnaces (Les transformateurs pour fours électriques), G. Marty. *Jl. du Four Electrique (Paris)*, vol. 39, no. 10, Oct. 1930, pp. 378-380, 3 figs. Special characteristics, wiring diagrams of supply transformers with three regulating taps, one for continuous regulation. (To be continued.)

Electric Heating

MATERIALS. Tentative Methods of Chemical Analysis of Metallic Materials for Electrical Heating. *Am. Soc. Testing Matls.—Tentative Standards*, 1930, pp. 133-151, 2 figs. Outline of method covers; solutions required, determination of chromium, determination of manganese, determination of carbon, determination of insoluble residue, determination of silicon, determination of sulphur, determination of copper.

Electric Lines

ICE FORMATION. Currents Required to Remove Conductor "Sleet," J. E. Cl m. *Elec. World*, vol. 96, no. 23, Dec. 6, 1930, pp. 1053-1056, 3 figs. Formula and alignment charts for calculating of preventing formation of ice; amperes required to prevent ice formation; current and temperature required to prevent sleet adherence; current and time required to melt ice; amperes required to melt off glaze.

Floodlighting

Short Cuts to the Solution of Floodlighting Problems, H. E. Butler. *Gen. Elec. Rev.*, vol. 33, no. 12, Dec. 1930, pp. 690-698, numerous figs. partly on supp. plate. Comments upon scope and tend of modern floodlighting; data for computation of floodlighting installations; sample problems; typical installations; summary of requirements; chart of floodlighting data and characteristics; partial list of athletic fields lighted with General Electric equipment.

Generators

ALTERNATING CURRENT. Flywheel Type Alternators in the Tropics, J. Finkelstein. *AEG Progress (Berlin)*, vol. 6, no. 12, Dec. 1930, p. 358, 1 fig. Description of AEG 860 kva., 6600 volt alternator for Dutch East Indies power station, Magelang, Java to work with airless injection 975 hp., 214 r. p. m., 6-cylinder 4-stroke cycle Diesel engine made by Messrs. Gebr. Sulzer, Winterthur.

Hydroelectric

POWER DEVELOPMENTS. Hydroelectric Utilizations in Irrigation Projects (Los Aprovechamientos Hidroelectricos en los Proyectos de Irrigacion), J. Herrera y Lasso. *Irrigacion en Mexico (Mexico, D. F.)*, vol. 1, no. 1, May 1930, pp. 22-26, 2 figs. How power development affects financing of irrigation systems; factors in study of probable power markets.

Illuminating Engineering

TERMINOLOGY. Revision of the American Standard Illuminating Engineering Nomenclature and Photometric Standards. *Illum. Eng. Soc.—Trans.*, vol. 25, no. 8, Oct. 1930, pp. 725-741. Activities and duties of Society's Committee on Nomenclature and standards; standard nomenclature, as revised to present time, is given.

Industrial Plants

ELECTRIC POWER. Economical Control of Purchased Electrical Power in the Industrial Plant, R. F. Gale. *Iron and Steel Engr.*, vol. 7, no. 21, Nov. 1930, pp. 536-537, 5 figs. Methods of obtaining high load factors by proper coordination of purchased and manufactured power used by Midvale Co., Philadelphia; day load peak 7500 kw. is approximately 3500 kw. greater than night load peak 4000 kw.

Insulating Materials

PAPER. Tentative Methods of Testing Untreated Insulating Paper. *Am. Soc. Testing Matls.—Tentative Standards*, 1930, pp. 571-589, 7 figs. Methods apply to untreated paper which is to be used as electrical insulator or as constituent of composite material used for electrical insulating purposes.

Properties, Tests and Applications of Papers in Electrical Industry (Propriétés, essais et applications des papiers en électrotechnique), A. R. Matthis. *Chimie et Industrie (Paris)*, Mar. 1930, (special no.) pp. 445-451. Properties required of such papers are briefly outlined, together with various tests to which they are subjected.

SLATE. Tentative Methods of Test for Determining the Insulating Qualities of Slate. *Am. Soc. Testing Matls.—Tentative Standards*, 1930, pp. 524-526. Method A covers determination of impedance leakage current flowing in high-voltage winding of transformer by means of ammeter in low voltage winding; method B covers determination of impedance leakage current flowing in high-voltage winding of transformer or specific ohmic impedance of slate by reading two voltmeters in low-voltage circuit.

TESTING. Tentative Methods of Testing Laminated Sheet Insulating Materials. *Am. Soc. Testing Matls.—Tentative Standards,* 1930, pp. 590-597, 1 fig. Tests apply to laminated flat sheet materials intended for use as electrical insulation.

Insulators

OIL-RESIN. Study of Electric Behavior of Oil-Resin Compounds with Special Regard to Range of Relatively Low Temperatures (Untersuchung ueber das dielektrische Verhalten von Oel-Harzimschungen unter besonderer Beruecksichtigung des Bereiches relativ geringer Temperaturen), E. Jirch and W. Riebel. *Archiv fuer Elektrotechnik (Berlin),* vol. 24, no. 4, Nov. 7, 1930, pp. 553-560, 11 figs. Relation between dielectric constants, angle of error and viscosity in range from 0 to 150 cent. at relatively low temperatures; phenomena are studied on theory of polar molecules of Debye.

PORCELAIN. Electrical Porcelain, J. K. Gillett. *Elecn. (Lond.),* vol. 105, no. 2737, Nov. 14, 1930, pp. 588-589, 5 figs. Tests for porosity; effect of glazes on mechanical and thermal properties; breakdowns caused by cementing. Bibliography. (Concluded.)

SPECIFICATIONS. British Standard Specifications for Porcelain Insulators for Overhead Power Lines. *Brit. Eng. Standards Assn.—Specifications (Lond.),* no. 137, 1930, 29 pp., 6 figs. Specification is applicable to porcelain insulators for overhead power lines at declared voltages and station voltages of 3 and 3.3 kv. respectively and upwards.

SUSPENSION. Suspension Insulators (Quelques remarques sur les isolateurs suspendux), Lequerier. *Société Belge des Electriciens—Bul. Mensuel (Brussels),* vol. 46, Nov. 1930, pp. 556-588, 10 figs. Comparison of types, characteristics, notes on testing and testing equipment, strength curves, high tension testing, arcing protection, etc.

TESTING. The European Insulator Situation, T. Rich. *Elec. Times (Lond.),* vol. 78, nos. 2037, 2039 and 2040, Nov. 6, 1930, pp. 787-788, Nov. 20, pp. 883-884, and Nov. 27, pp. 929-932, 14 figs. Notes on recent developments and in testing laboratories in particular; routine testing department and articles of equipment of two million volt laboratory of Rosenthal Works in Bavaria, previously indexed from various sources.

Lamps

GLOW. Gas Discharge Tubes in Television Practise (Die Gasentladungsroehren in der Fernsehtechnik), H. Ewest. *Fernsehen (Berlin),* vol. 1, no. 2, Feb. 1930, pp. 59-62, 3 figs. Characteristics of inertia free glow lamps and their suitability for television purposes outlined in general way; various types.

The Glow Lamp as Television Light Relay (Die Glimmlampe als Fernseh-Lichtrelais), F. Kirschstein. *Fernsehen (Berlin),* vol. 1, no. 11-12, Nov. 1930, pp. 495-501, 8 figs. Hysteresis of glow lamp is discussed; dynamic and static characteristic; a. c. characteristics, measurement of hysteresis; a. c. resistance as function of frequency; control of glow lamp by output tube, etc.

MANUFACTURE. Some Recent Developments in Lamp Manufacturing, J. A. Jones and E. I. Morwick. *Elec. News (Toronto),* vol. 39, no. 22, Nov. 15, 1930, pp. 39-40 and 48, 4 figs. Combination of ultra-violet and visible radiation gives promise of developing new era of lighting for health maintenance and general illumination; development of S-1 lamps, science has successfully limited wavelengths, shorter than those usually found in sunlight; cut-off in natural sunlight is about 2800 A; spectrum of radiation, bulb transmission and response curves are given. (Concluded.)

Lighting

INDUSTRIAL. Current Industrial Lighting Practise, R. B. Brown, Jr. *Illum. Eng. Soc.—Trans.,* vol. 25, no. 8, Oct. 1930, pp. 716-724. Data and other information calculated to show modern trends in industrial lighting practise; facts and figures have been supplied by several lighting equipment manufacturers and illuminating engineers covering such items as variation in reflector sizes over period of years, as well as distribution of lamp sizes and types of reflector equipment most commonly used; present practise is shown from data supplied by several central-station lighting service engineers from which several definite conclusions are drawn.

VISION RELATIONSHIP. Lighting Plus Vision Equals Seeing, M. Luckiesh and F. K. Moss. *Illum. Eng. Soc.—Trans.,* vol. 25, no. 9, Nov. 1930, pp. 807-824 and (discussion) 824-825, 5 figs. Further attempts to interpret data on various relationships of fundamental factors of vision into lighting practice; scientific basis of satisfactory demonstrations of influence of lighting upon seeing is discussed and successful demonstrations are described and illustrated; various papers by authors represent series beginning with purely scientific data and proceeding, step by step, toward lighting practice.

Loud Speakers

Loudspeakers, S. G. Brown. *Elecn. (Lond.),* vol. 105, no. 2741, Dec. 12, 1930, p. 749. Critical discussion of paper on "Loudspeakers" Since Their Conception with Gramophone Pick-ups and Wireless Recording Apparatus, presented before Inst. Elec. Eng. Great Britain, in London.

An Efficient Loud Speaker at the Higher Audible Frequencies, L. G. Bostwick. *Acoustical Soc. Am.—Jl.,* vol. 2, no. 2, Oct. 1930, pp. 242-250, 5 figs. Purpose of this paper is to describe loud speaker by which it has been possible to obtain efficient radiation of these very high frequencies; this loud speaker is intended for use as adjunct to either baffle or horn type loud speakers to extend range of efficient performance to 11,000 or 12,000 cycles.

ELECTROSTATIC. Theory of the Electrostatic Loud Speaker, C. R. Hanna. *Acoustical Soc. Am.—Jl.,* vol. 2, no. 2, Oct. 1930, pp. 143-149, 2 figs. It is proved that force per unit voltage in electrostatic device is similar function of capacity and negative stiffness due to steady electrostatic field; new concept called Motional admittance is introduced for electrostatic loud speaker and this is shown to be similar in its mathematical form to Motional Impedance of electromagnetic driver; calculation of ultimate theoretical efficiency that may be obtained with electrostatic speaker having pure resistance radiator and covering given frequency range is given.

MEASUREMENT. Loud Speaker Sound Pressure Measurements, E. W. Kellog. *Acoustical Soc. Am.—Jl.,* vol. 2, no. 2, Oct. 1930, pp. 157-200, 18 figs. General test conditions and precautions; comparison of loud speaker system with direct listening; standing wave patterns; compensation for selective absorption in room; advantages of directive loud speakers; test information required to estimate merit; free space measurements; indoor test; moving microphone system; warble method; rapid frequency change method; close up tests; measurements of total output; experimental results; additional data needed; pressure and velocity in neighboroood of small simple source.

Magnetic Measurements

UNITS. New Electromagnetic Unit; One Oersted (En Ny Elektromagnetisk Enhed: En Oersted), A. W. Marke. *Ingenioren (Copenhagen),* vol. 39, no. 45, Nov. 8, 1930, pp. 537-539, 1 fig. International Electrotechnical Commission, in meeting at Copenhagen in June 1930, approved new absolute unit for intensity of field and called it "one oersted;" events leading up to this decision and physical definition of unit.

Remarks on the Decisions of International Electrical Commission with Regard to Magnetic Units (Observations sur les décisions de la Commission électrotechnique internationale concernant les unités magnétiques), E. Brylinski. *Revue Générale de L'Electricité (Paris),* vol. 28, no. 19, Nov. 8, 1930, pp. 722-725. Author concludes that reserves made by Kennelly with respect to use of prefix "Pra" for practical units are without ground as units so characterized can leave no room for doubt.

Metering

The Metering of Three-Phase Supplies, O. Howarth. *Instn. Elec. Engrs.—Advance Paper,* 1930, 13 pp., 13 figs. Large bulk supplies are most complex and demand high standard of accuracy for commercial reasons; unfortunately, each additional complexity introduces additional source of error, and inaccuracies introduced by auxiliary apparatus and special fitments are discussed.

Meters

Summation Metering Equipment. *Engineer (Lond.),* vol. 150, no. 3908, Dec. 5, 1930, pp. 628-629, 6 figs. Ferranti equipment is described: diagram shows equipment required for summation metering of complete station having two-way transformer circuits, three generators, and station auxiliary machine; mechanism consists of two-way contactor driven by auxiliary spindle geared to main meter spindle, and is fitted with heavy silver contacts moved positively in each direction by jewelled rollers bearing on cam.

FREQUENCY. A New Frequency Meter, C. L. Lipman. *Elec. Rev. (Lond.),* vol. 107, no. 2763, Nov. 7, 1930, pp. 793-794, 4 figs. New deflectional-type instrument for measurement of power frequencies.

Mining

ELECTRIC EQUIPMENT. New Mining Electrical Control Gear. *Engineer (Lond.),* vol. 150, no. 3905, Nov. 1930, pp. 546-547, 8 figs. For use in mines, Metropolitan-Vickers Electrical Co., has introduced some new control gear, including self contained controller; mining switch units, also supplied as gate end boxes and mining transformer units; and plug distribution boxes.

ELECTRIC HAZARDS. Selected List of Bureau of Mines Publications Covering Safety Studies and Activities of the Electrical Section, L. C. Ilsley. *Coal Min.,* vol. 7, no. 10, Oct. 1930, pp. 489-491. Previously indexed from U. S. Bur. Mines—Information Cir., no. 6310, July 1930.

Motors

INDUCTION. Motor Selection Improves Power Factor, L. F. Leurey. *Elec. West,* vol. 65, no. 6, Dec. 1, 1930, pp. 292-295, 3 figs. Conclusions are that induction motors should be selected with highest possible speed consistent with practical gear reduction; and operated at highest possible percentage of rated capacity; this especially applies to wound rotor motors intended for variable speed operation.

INDUCTION—STARTING. Use of Induction Motors with Short Circuited Rotor (Sur l'emploi des moteurs asynchrones en court-circuit), J. Le Monnier. *Revue Générale de l'Electricité (Paris),* vol. 28, no. 20, Nov. 15, 1930, pp. 771-779, 9 figs. Squirrel cage motor is only one case of short-circuited rotor type; starting of Boucherot double cage motor; starting of simple motor; experimental verification of starting characteristics; starting current diagrams; braking; influence of power factor; starting by insertion of resistance or inductance in stator circuit.

SYNCHRONOUS. Synchronous Motors, A. H. v. Altmann. *AEG Progress (Berlin),* vol. 6, no. 12, Dec. 1930, pp. 366-371, 4 figs. Characteristics of synchronous motors; overload and fluctuations in torque; network voltage fluctuations; network frequency fluctuations; advantages over other machines; starting methods.

Networks

INTERCONNECTED. Power Flow Studies in Interconnected Systems, P. B. Juhnke. *Gen. Elec. Rev.,* vol. 33, no. 12, Dec. 1930, pp. 670-673, 6 figs. For purpose of helping such study, series of diagrams were constructed for Chicago District for different periods and seasons of immediate years ahead, and for peak periods even decade in advance; four systems involved are operating as one system, by virtue of Interchange Energy Contract, and comprise what is commonly known as Chicago Regional System.

STABILITY. Power-System Stability, R. D. Booth and O. G. C. Dahl. *Gen. Elec. Rev.,* vol. 33, no. 12, Dec. 1930, pp. 677-681, 1 fig. Comprehensive and non-mathematical review of stability problem; review of general problem of power-system stability in light of present knowledge; aspects which still are in controversial and unsettled state as, for instance, effect of damper windings, and influence of various methods of grounding high-tension neutral points. (To be continued.)

Power Factor

CORRECTION. Improvement of Power Factor. *Elec. Times (Lond.),* vol. 78, no. 2040, Nov. 27, 1930, pp. 937-939, 7 figs. Use of electrostatic condensers for correction of low power factors.

Power Generation

Balance Between the Supply and the Consumption of Energy, R. W. Miller. *Elec. Engr. of Australia and New Zealand (Melbourne),* vol. 7, no. 7, Oct. 15, 1930, pp. 235-240, 2 figs. Main factors which affect cost of electrical energy and means that can be adopted to effect economies; basic problem arises from fact that electricity cannot be stored, and therefore various expedients have to be adopted in adjusting supply to cope with demand; it is shown how hydroelectric storage plants may be used to level up demand on base load stations; modern developments in steam power station practice. (To be concluded.)

Power Industry

Congress of the International Association of Producers and Distributors of Electric Power in Brussels, September 1930 [Congrès de Bruxelles de l'Union internationale des Producteurs et Distributeurs d'Energie électrique (Septembre 1930)]. *Revue Générale de Electricité (Paris)*, vol. 28, nos. 20 and 21, Nov. 15, 1930, pp. 765-770 and Nov. 22, 1930, pp. 803-812. Discussions on reported improvements in equipment of thermal generating stations in Belgium, Argentina and Italy; interconnection of metallurgical plants in Briey region; unification of frequencies; smoke abatement, etc.

Power Supply

RURAL. The Status of Research in Rural Electrification, G. W. Kable. *Elec. Jl.*, vol. 27, no. 12, Dec. 1930, pp. 705-707. Since beginning of organized research in 1923, 24 states have undertaken investigational programs; primary purpose of these surveys has been to learn something of use, demand, cost, and value of electric service on farm, and fundamental difficulties involved in extension of this service; in order to have satisfactory uses for electricity on farm.

Photoelectric Cells

Photo-electric Cells, T. Thorne Baker. *Elec Rev. (Lond.)*, vol. 107, no. 2763, Nov. 7, 1930 pp. 768-769, 3 figs. Circuit with one-valve amplification; bridge circuit for lamp photometry; automatic lighting controller. (Concluded.)

SELENIUM. The Selenium Cell; its Properties and Applications, G. P. Barnard. N. Y., Richard R. Smith, Inc., 1930, 331 pp., illus., diagrs., $9.00. Valuable monograph aims to present precise, accurate survey of knowledge of properties of selenium and of applications of selenium cells to photophony, television, talking films and other practical uses; scattered literature has been very thoroughly summarized and exhaustive bibliography is included in book, which will be found most useful by all workers in this field. Eng. Soc. Lib., N. Y.

Power Plants

PEAK LOADS. Storing Power for Peak Loads, W. H. Onken, Jr. *Nat. Elec. Light Assn.—Bul.*, vol. 17, no. 12, Dec. 1930, pp. 759-761 and 800, 4 figs. Practices of European electric power system in utilizing stored steam and pumped water for auxiliary power during peak loads or in emergencies.

STEAM AND DIESEL. Diesel Power—With Steam Combination. *Power*, vol. 72, no. 22, Nov. 25, 1930, pp. 842-845, 3 figs. Diesel hook-ups shown range from simplest to more complex, former being more typical of current practice; for given power output diesel receives and rejects less heat; however, methods and equipment for conserving waste heat are available wherever economic conditions justify their use.

STEAM AND HYDROELECTRIC. Steam and Hydro Combined for Power and Process. *Power*, vol. 72, no. 21, Nov. 18, 1930, pp. 786-790, 5 figs. Dalhousie plant of New Brunswick International Paper Co. is typical of interrelation of water-power development and paper industry in Canada; 6000-kw. steam turbine and 425-lb. boilers for process steam and emergency service insures reliable operation of 570-ton paper mill when hydro power is obtained over single 110-mi. transmission line; sectional elevation and principal equipment in power plant.

Railroads

POWER SUPPLY. Supply Lines for Single Phase Railroads (Speiseleitungen von Einphasenbahnen), E. Wist. *Elektrotechnik und Maschinenbau (Vienna)*, vol. 48, no. 43, Oct. 26, 1930, pp. 970-972, 1 fig. Analysis of requirements and economical relations between plant, lines and networks; numerical example of 100 kv. line of 240 sq. lines and networks; numerical example of 100 kv. 100 km. line of 240 sq. mm. cross-sectional area for 33,000 kw.

SUBSTATIONS. Omaha Changes Power System To Raise Speed. *Traction Shop and Roadway*, vol. 3, no. 11, Nov. 1930, pp. 327-329, 4 figs., see also *Elec. Traction*, vol. 26, no. 11, Nov. 1930, pp. 566-568, 4 figs. Installation of nine automatic substations, installed throughout system of Omaha and Council Bluffs street railway, eliminate steam power plant, retire old cars and raise average car speed.

Rectifiers

COPPER OXIDE. Copper Oxide Rectifiers, K. Singh and I. R. Smith. *Elec. Times (Lond.)*, vol. 78, no. 2041, Dec. 4, 1930, pp. 975-979, 11 figs. Some consideration of their properties and their electrochemical action in general; actual characteristics and applications of copper oxid rectifiers in practice.

Radio

BROADCASTING. The Importance of Phase Control in Synchronizing, C. W. Horn. *Electronics*, vol. 1, no. 9, Dec. 1930, p. 423. Results of experiments carried out with cooperation of National Broadcasting Co., Radio Corporation of America, and American Telephone and Telegraph Co.; experimenting stations were maintained not only at same frequency but in fixed phase relation, several important and encouraging events transpired, no longer was program coming to local listeners disturbed, much area disappeared and those listeners in this area experienced increase in local field strength.

DETECTORS. Some Properties of Grid Leak Power Detection, F. E. Terman and N. R. Morgan. *Inst. Radio Engrs.—Proc.*, vol. 18, no. 12, Dec. 1930, pp. 2160-2175, 8 figs. It is shown theoretically that grid power detection can be obtained without undue distortion provided grid condenser reactance to modulation frequency, and grid leak resistance are related to degree of modulation in definite way; load limit of grid-leak power detector is point where plate rectification becomes appreciable, i. e., when straight line part of plate characteristic is exceeded; experimental results are given which verify theoretically determined point at which distortion becomes excessive.

Radio Frequency

STANDARDS. An International Comparison of Frequency by Means of a Luminous Quartz Resonator, S. Jimbo. *Inst. Radio Engrs.—Proc.*, vol. 18, no. 11, Nov. 1930, pp. 1930-1934, 1 fig. International comparison of frequency standards made with luminous quartz resonator shows different laboratories to be in agreement to one part in 100,000 when used to calibrate resonator at its flexual fundamental of about 10 kc.; observed agreement seems limited by luminous glow resonator used rather than by any difference between laboratory standards compared.

Relays

Theory and Application of Relay Systems, P. H. Robinson and I. T. Monseth. *Elec. Jl.*, vol. 27, no. 12, Dec. 1930, pp. 720-726, and 728, 13 figs. Transmission line protective relays; nine major types of protective relays are used; after fundamental characteristics of these are fixed in mind, it is easy to remember combination of types used to give complete selective protection to particular arrangement of transmission lines; various types are discussed. (To be continued.)

Ship Propulsion

ELECTRIC. Wider Use of Electric Power for Propelling Ships, D. W. Niven. *Mar. Rev.*, vol. 60, no. 12, Dec. 1930, p. 43. Review of growing application of electric power to ship propulsion.

Telegraph Systems

Developments in Machine Telegraph Systems and Methods of Operation, H. H. Harrison. *Instn. Elec. Engrs.—Jl. (Lond.)*, vol. 68, no. 407, Nov. 1930, pp. 1369-1453 and (discussion) 1453-1468, 141 figs. Speed and phase control; definition of synchronism; motor speed control; governors; phase control; methods of generation of correction impulses; control of tuning-fork speed and phase by line signals; start-stop synchronism; local synchronism; general principles of synchronizing schemes; speed and phase indicators; phase adjustment or orientation; tuning forms; phonic-wheel motors; distributor construction and speed; rates of vibration of tuning of forks. Bibliography.

Telephone

CARRIER CURRENT. Function of Repeating Coils in Carrier Circuits, A. G. Ganz. *Bell Laboratories Rec.*, vol. 9, no. 3, Nov. 1930, pp. 134-136, 2 figs. Lack of metallic connection assists in keeping stray noise-producing voltages, picked up by line and transmitted longitudinally, from passing through terminal circuits; repeating coil also allows less-expensive unbalanced apparatus to be used without disturbing balance of line wires to ground.

TESTING. Comparative Transmission Tests, B. C. Burden. *Telephone Engr.*, vol. 34, no. 11, Nov. 1930, pp. 23-27, 6 figs. Notes on practical methods of testing efficiency of subsets, transmitters, and receivers; practical application of DB; transmission losses; transmission factors; loop losses; transmission loss due to eavesdropping on multi-party lines; transmission loss in central office equipment; transmission efficiency of subsets; transmission losses due to improper use of instruments; transmission losses in trunk plant; transmission testing circuits for determining instrument efficiency.

Telephone Relays

MAGNETIC INTERFERENCE. Effect of Magnetic Interference on Relay Operation, W. Buhler. *Bell Lab. Rec.*, vol. 9, no. 3, Nov. 1930, pp. 110-114, 5 figs. Part spreads out and returns to back end of core over longer path through air; any iron in vicinity due to its high permeability would become likely path for this stray flux to follow; because of this cores and armatures of nearby relays often serve to conduct stray flux; magnetic flux, which causes pull.

Television

Photoelectric Cells, Scanning Discs, Tiny Motors and Tube Current Meters, New Tools for Research, E. L. Manning. *Projection Eng.*, vol. 2, no. 11, Nov. 1930, pp. 20 and 24. Notes on equipment used in public television demonstration in Schenectady in which complete vaudeville program was transmitted 2 miles away from theater where it was presented.

Trackless Trolleys

DETROIT. Trolley Bus Operation Proves Advantageous at Detroit. *Elec. Ry. Jl.*, vol. 74, no. 13, Dec. 1930, pp. 753-754, 3 figs. Decreased operating costs, increased traffic, improved public relations, and almost entire freedom from accidents are advantages of trolley bus operation on Plymouth Road, Detroit.

GERMANY. Electric Trolley Bus Line Mettmann-Gruiten (Der lektrische Fahrdragtbus-Betrieb Mettmann-Gruiten), A. Schiffer. *Verkehrstechnik (Berlin)*, no. 38-39, Sept. 19, 1930, pp. 501-505, 5 figs. First modern electric trolley-bus line in Germany of Rheinisch-Westfaelische Elektrizitaetswerk, Essen; line of 5.77 km. total length is very much curved and only .86 per cent horizontal, rest is distributed over gradings from 1 to 10 and 1 to 30 inclinations; equipment described is run by 89 kw. 1425 r. p. m. at 750 to 800-volt d. c.; gear ratio 1:11.8.

Transmission and Distribution

Generation, Transmission and Distribution, H. R. Woodrow. *Power Plant Eng.*, vol. 34, no. 24, Dec. 15, 1930, pp. 1415-1418, 3 figs. Developments in electric systems process indicates improved network protection, development of vertical a.c. networks, better cable design and larger generators.

Vacuum Tubes

DETECTOR. The Estimation of the Sensitivity of the Grid Rectifier for Large Inputs, C. D. Hall. *Experimental Wireless (Lond.)*, vol. 7, no. 87, Dec. 1930, pp. 668-670, 5 figs. Measurements on sensitivity of grid rectifier using low impedance valves of "L" type with high anode voltages followed by resistance coupling; when practical results were compared with theoretical curve, former showed much smaller output than latter; as result of experiment, it was found to be due to small time constant or grid condenser and leak circuit.

Welding

ALLOY STEEL. Welding of Corrosion Resisting Steels, W. Spraragen. *Welding*, vol. 1, no. 14, Dec. 1930, pp. 979-980 and 985, 5 figs. General instructions covering welding technique used in arc welding, gas welding, resistance welding, and welding with shielded arc.

ARC. Significance of Welding of Depth in Arc Welding and Means for Improving (Die Bedeutung der Einbrandtiefe beim Lichtbogenschweissen und die Mittel zu ihrer Verbesserung), E. Schwartz. *V.D.I. Zeit. (Berlin)*, vol. 74, no. 46, Nov. 15, 1930, pp. 1565-1567, 18 figs. Factors controlling welding depth in d.c. arc welding; importance of welding depth for different types of joints and materials.

BOILERS. Welded Boiler, J. C. Hodge. *Mar. Eng. and Shipp. Age*, vol. 35, no. 12, Dec. 1930, pp. 652-658, 13 figs. Bureau of Engineering, U. S. Navy, has adopted arc-welded construction for joints of drums for 24 boilers now being built by Babcock & Wilcox Co., for new scout cruisers Minneapolis, New Orleans and Astoria; specifications drawn up are based on proposed specifications for fusion welding of drums or shells of power boilers published by A.S.M.E. boiler code committee; specifications governing test procedure.

BRONZE. Bronze Welding of Steel and Cast Iron, T. D. Ketchbaw. *Welding*, vol. 1, no. 14, Dec. 1930, pp. 981-985, 4 figs. General technique and property of bronze welds with particular reference to welding of locomotive frames and cylinders; tensile strength of bronze weld, properly made is around 50,000 lb. per sq. in.

BUILDINGS. Arc Welding on Steel Buildings, F. P. McKibben. *Civil Eng., (N. Y.)*, vol. 1, no. 3, Dec. 1930, pp. 205-206. Discussion by F. T. Llewellyn, H. M. Priest, J. L. Faden and S. H. Widdicombe of paper indexed from issue of Oct. 1930.

MACHINERY. Electric Welding and its Applications in the Manufacture of Electric Machinery (La soudure électrique et ses applications dans la construction des machines électriques), Taphanel and Weber. *Revue d'Electricité et de Mécanique (Paris)*, no. 13, Sept.-Oct. 1930, pp. 19-34, 34 figs. General notes on possibilities of electric welding; welding applied in electric manufacture plant construction illustrated by welded structures in France and of General Electric Plant in Philadelphia; applications of welding in machinery and equipment manufactured by Als. Thom. Co.

PIPE. Fusion Welding Specifications for Steel and Wrought Iron Pipe, J. H. Zink. *Welding*, vol. 1, no. 14, Dec. 1930, pp. 975-978, 7 figs. Specification adopted by Heating & Piping Contractors Assn. as to workmanship, design, and materials; single vee type joint; tables and sketches give data on beveling, spacing and tacking; fillet welds; welding neck flanges; tube turns; swages or reducers; dimensions and shapes of tee and angle joints.

PIPE LINES. Arc Welded Pipe Lines for Steam and Water Service, C. M. Taylor. *Plumbers and Heat. Contractors Trade Jl.*, vol. 89, no. 12, Dec. 15, 1930, pp. 17-18, 8 figs. Advantages of electric welding outlined with directions on how joints, reducers and plugs are to be made.

REPAIR SHOPS. Railroad Shops Save by Welding, J. C. Coyle. *West. Machy. World*, vol. 21, no. 11, Nov. 1930, pp. 489-491, 9 figs. Methods at Denver locomotive shops of Burlington railroad for repairing cylinder cracks, worn cross-heads, stoker screw, broken bolts, patching of fire-boxes, etc.; data on savings.

Welding Machines

Heavy Duty Butt Flash Welding Machines. *Engineer (Lond.)*, vol. 150, no. 3905, Nov. 14, 1930, p. 540. Extensive trials having shown that butt welding is satisfactory for certain purposes and that quality of weld may be equal to that of solid material, method is now widely adopted in railway works, shipyards, etc.; A.E.G. of Berlin, has designed machines in which clamping device is accessible on all sides and in which transformer is water cooled.

Development of Welding Equipment According to Langmuir Process in America and Germany (Die Entwicklung der Schweissgeraete nach dem Langmuir-Verfahren in Amerika und Deutschland), S. Sandelowsky. *Elektrotechnische Zeit. (Berlin)*, vol. 51, no. 58, Nov. 27, 1930, pp. 1649-1652, 11 figs. Electric equipment, transformers, etc., of arc atom welding process of General Electric Co. and development of same equipment at AEG; voltage protection.

Welds

TESTING. A Study of Welded Metals Under Fatigue Tests, G. E. Thorton. *Am. Welding Soc.—Jl.*, vol. 9, no. 10, Oct. 1930, pp. 48-66, 14 figs. Testing procedure and results obtained by Department of Mechanical Engineering of State College of Washington, in cooperation with American Bureau of Welding; sketch illustrates construction of Farmer type rotating beam testing machines; graphs and tables give data on properties of oxyacetylene weld, atomic hydrogen weld, metal arc weld; microphotograph illustrates crystal structure in weld and parent metal.

Tensile Tests for Welds, J. W. Owens. *Am. Welding Soc.—Jl.*, vol. 9, no. 10, Oct. 1930, pp. 79-88, 7 figs. Suggestions relating to standard A.S.T.M. tensile test specimens now used for fusion butt welds; sketches illustrate development of suitable shape of tension specimen to determine fusion and value of weld as joint; results of tests obtained with weld metal of high tensile strength and fair ductility.

Wiring

OFFICE BUILDINGS. Specifications for Electric Power Requirements in a Moderate Sized Office Building, J. C. Runyon. *Elec. Specifications*, vol. 2, no. 6, Dec. 1930, pp. 27-34. Sample specifications of moderate size office building of from 100,000 to 200,000 sq. ft. floor area. (To be continued.)

Electrical Installation in the Moderate Sized Office Building, F. Latzer. *Elec. Specifications*, vol. 2, no. 6, Dec. 1930, pp. 17-22 and 39, 7 figs. Lighting system layout of Park Building, Yonkers, N. Y. is described in detail; notes on metering; construction details; wiring devices; power system; service details; signal system.

Employment Notes

Of the Engineering Societies Employment Service

Positions Available

PHYSICIST OR ENGINEER to carry out research and testing on electric meters. Apply by letter only, stating age, race, nationality, education, technical experience and references. Location, Canada. W-2153.

MECHANICAL ENGINEER, Polish, with long experience in electric furnace castings. Must be conversant in tempering and forging works. Apply only by letter. Location, Europe. W-1920.

CHIEF OF ELECTRICAL INSTRUMENT ENGINEERING for manufacturer of electrical apparatus. It is essential that the applicant be able and willing to fit into an old and closely knit organization; that he be thoroughly familiar with the mathematical methods of instrument design, and that he have a knack and a liking for small mechanisms. While the financial return will be based on results and will eventually be adequate the attractiveness of this opening lies in the opportunity for real engineering achievement. Apply only by letter. Location, New York. W-2209.

Men Available

ELECTRICAL ENGINEER, 36, single, European education, North American training, good executive, nine languages. Eight years' experience, construction, maintenance; operation large public utility plants. Seven years' sales experience, various branches, expert in exports and government supplies, traveled over the world. Adaptable to any country, climate. Available now. Desires position abroad. C-8351.

GRADUATE ELECTRICAL ENGINEER, 1929, 22, single; 15 months on General Electric test course. Desires position with utility or manufacturing company or with concern doing consulting or construction engineering. Available immediately. Location, New England preferred. C-8028.

PUBLIC UTILITY ENGINEER, college graduate, class 1925. Married. Five years' general engineering experience on distribution and transmission work. Also wide construction experience, maintenance and operating supervision, appraisal, valuation, right-of-way, forecasting future load, commercial and power sales work, etc. Location, immaterial. C-4001.

GRADUATE ELECTRICAL ENGINEER, 26, single, 10 years' experience in motion picture projection; one year radio. Desires connection with concern interested in production end of motion pictures or television. Location, immaterial. Future behind position controlling factor. C-7934.

ELECTRICAL ENGINEER, 40, with mining, steel, and general industrial experience, available at once. Four years' in technical publishing, editorial capacity. Interested in research and development work, plants and processes, industrial investigations and financing plant operations, or general engineering. East preferred. B-4905.

GRADUATE ELECTRICAL ENGINEER, B. S. degree, one and a half years with large electrical manufacturing concern in test and research departments; also familiar with repair work on distribution transformers and other apparatus. Available on short notice. Location preferred, New England or eastern part of country. C-8075.

ELECTRICAL ENGINEER, graduate, 33, married. Twelve years' experience, last six years in Latin America; for four years designed electrical machinery; five years public utilities, planning, design, supervision of construction of power plants and substations, three years chief electrical engineer raw sugar factory; fluent Spanish. Available February. Location preferred, New York City, vicinity. C-8553.

GRADUATE ELECTRICAL ENGINEER; 17 years' experience in electrical manufacturing; electric railway, power plant, substation and transmission line design and construction, desires connection with real opportunity. C-8256.

ELECTRICAL ENGINEER, university graduate, age 29, married. Seven years' varied experience in electrical design, purchasing and estimating for large power plant work. Also industrial, theater, apartment and office building experience with contracting engineers. Field and office. Desires position with engineering or contracting organization. Location preferred in the East. B-7454.

ELECTRICAL ENGINEER, 31, B. S.-E. E., 1926. One year as assistant electrical engineer making preliminary studies, investigations on hydroelectric projects; one year engineer, electrical control of armament on aeroplanes; two years car, material inspector, street railway company; one year student engineer large public utility; two years' electric car shop experience. C-6077.

INSTRUCTOR, graduate E. E. of a grade A European University and M. S. of a Southern University. Two years' teaching experience. Best references. Available June 1, 1931. Location, immaterial. C-8580.

COLLEGE GRADUATE, B. S. degree, Wesleyan University, 1924, in electricity, physics, mathematics. One year electrical test, meters. Six years electrician, power and light manager, estimating. Desires position as junior engineer in laboratory. Would consider position as chief electrician in manufacturing plant. Location, East. Available immediately. C-4294.

GRADUATE ELECTRICAL-MECHANICAL ENGINEER, 36, desires connection with public utility or industrial firm on power-station operation as engineer, or assistant to superintendent or engineer. Ten years' experience power-plant test, operation, design, construction, maintenance. Three years' electrical engineer for industrial concern. Two years assistant to power engineer. B-8379.

ASSISTANT EXECUTIVE, 39, married, technically trained. Connections with large public utility, manufacturers, and industrial consultants on work of administrative and commercial research nature. Especially qualified as assistant to busy executive needing man with management ability. Well endorsed. Prefer East. B-9122.

ARMATURE WINDER, 18 years' shop experience. Capable of handling all kinds of electrical motor repairs up to 250 kw. either a-c. or d-c., able to do all kinds of windings, old or new styles. Familiar with wiring for light and power. Desires position in shop or as electrician maintaining factory or office building. C-7952.

ELECTRICAL ENGINEER, graduate, 36, married. Twelve years' experience; last five years with very active consulting engineer. Design, writing specifications and requisitions, cost estimates, industrial surveys, supervision of electrical installations covering new and extensions to existing power houses and industrial plants. Valuable to consulting engineer or industrial concern. Available at once. C-343.

1929 GRADUATE ELECTRICAL ENGINEER, age 24, with year and half experience in manual and dial telephone work. Prefers work in radio or sound reproduction. Location in or near Maryland preferred. Available on short notice. C-8581.

ELECTRICAL ENGINEER, Bachelor's and Master's degrees; fourteen years peculiarly broad experience in test, research and development, standardization, consultation, university teaching, executive work, personnel; familiar with both power and radio equipment and practise. Stability and opportunity primary, initial salary and location secondary. Available at once. C-4951.

DEVELOPMENT ENGINEER, 29, with exceptional abilities for electrical relay circuits, as supervisory, remote or automatic control, automatic telephony, alarm systems, etc. Solves circuit problems with minimum of equipment (relays, contacts) and in record time. Also resourceful in small apparatus design. University graduate. At present employed. Desires connections with larger company. C-8373.

GRADUATE ELECTRICAL ENGINEER, 27, married. Seven years' test and laboratory experience with large electrical manufacturing company. Desires position as electrical engineer with manufacturing company or public utility. C-8592.

JUNIOR ENGINEER, 25, single. Desires connection with public utility, sound picture industry or radio manufacturing firm. General Electric test course, public utility distribution test experience. Test, design, construction, maintenance and engineering work in radio receiver manufacturing plant. Location, East. C-8596.

GRADUATE ELECTRICAL ENGINEER, age 29, married. Five years' maintenance and construction work. Three years's design, test and service work in distribution and power transformers. Also some sales experience. Interested in position with mining, public utility company or industrial concern. Reasonable salary with company offering opportunity. C-8539.

GRADUATE ENGINEER, 21, single, graduate in electrical engineering with B. S. degree. Twelve months' experience on electric meters. Desires position with opportunity for advancement with utility, manufacturing, or other engineering concern. Location preferred, New York or vicinity. C-8387.

ELECTRICAL ENGINEER, 30, married, B. S. in E. E. graduate student course, Westinghouse; substation construction from handling the tools to field engineer; cost keeping and material handling in construction department. Last two years substation and underground vault design. Additional education; business finance, Geneva College; Business management, La Salle; system stability, Westinghouse. C-8572.

ELECTRICAL ENGINEER, 24, married. Experience with oscillographs, vacuum tube amplifiers, and portable wireless sending and receiving set. Has done test work for utility. Also surveying experience. Holds second grade commercial wireless operators license. C-3035.

VALUATION ENGINEER, all phases of complete valuations; to take charge or do anything else, electrically trained. Accounting experience. C-234.

GRADUATE ELECTRICAL ENGINEER, 27, married. Six years' experience in substation and generating station design with middle western utility. Two years' graduate study in utility economics. Technical writing experience. Available on three weeks' notice. C-1331.

ELECTRICAL ENGINEER, B. S. degree, Iowa State College 1929, 26, married; now employed. Has had one year experience in physical testing laboratory of Western Electric Company. Desires position in the radio or electrical industries with opportunity for advancement. Location preferred, Middle West. Available on two weeks' notice. C-8632.

GRADUATE ELECTRICAL ENGINEER, 31, single. Previous to college education, 8 years' experience as a licensed electrician. Now teaching physics and mathematics in Springfield, Massachusetts. C-8633.

RESEARCH ENGINEER, exceptional theoretical and research grounding. Thoroughly familiar with commercial instruments. Two years' public utility engineering. Three and one-half years' responsible executive and development experience in highly specialized technical industry. Prefer small corporation in United States. Best references and connections. C-6938.

GRADUATE ELECTRICAL ENGINEER, experienced on testing, developmental manufacturing, electrical plant construction, wide experience all features design of power stations, indoor and outdoor substations, and industrial light and power. Checker two years. Squad leader two years. Will consider any location. B-9222.

ELECTRICAL ENGINEER, single, 30, Scandinavian, graduate Swiss Federal Institute of Technology, Zurich, with 6½ years' experience, four of them in United States, with manufacturing, mining, public utility and sugar companies, including operation, test, layout, estimate, inspection, drafting and design. Desires permanent position with future. Speaks German and Spanish. C-3764.

ELECTRICAL DESIGNER AND DRAFTSMAN, age 31, single. Eight years' public utility experience in steam and hydroelectric plants, substations and industrial plants. Graduate of technical school in mechanical and electrical engineering. Desires position with public utility or industrial company. C-4510.

RESEARCH ENGINEER, 27, Westinghouse graduate engineer, United States citizen, married, returning from two and one-half years of graduate study in Germany. Desires position for fundamental research in physics or in electrical engineering with an industrial organization; location preferred, Eastern United States. C-8642.

PYROMETER ENGINEER, 25 years of age, christian, single. Graduate of electrical engineering extension course of Columbia University. Have had five years' experience as a field engineer for a well known manufacturer of industrial instruments. Experienced in the construction, application and selling of pyrometers and automatic valves. C-8647.

GRADUATE ELECTRICAL ENGINEER, 1930. Seven months' experience in electrical substation layouts with a public utility. Desires related position in drafting or testing. Age 22. C-8293.

GRADUATE ELECTRICAL ENGINEER, 35, married. Twelve years' experience of which five as junior executive, with street railway, power and light utilities. Qualified for position as assistant general executive or in transmission

ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco
N. D. Cook, Manager

205 West Wacker Drive
Chicago
A. K. Krauser, Manager

31 West 39th St.
New York
W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

Men Available.—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

Opportunities.—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

Voluntary Contributions.—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

Answers to Announcements.—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

or distribution department. Desires position with United States utility. Good references. Available immediately. C-5091.

DISTRIBUTION ENGINEER, 32, married. Six years' utility experience. Thoroughly familiar with organizing for economical maintenance, servicing, and construction, including records, accounting, reports. Some experience, steam power plant equipment, testing. Cornell University E. E. 1923. Now employed, junior executive on engineering and construction. Open for more responsible position, preferably in operating. C-5155.

ELECTRICAL ENGINEER, 37, married. Graduate from a German University. Fourteen years' experience in designing overhead and underground distribution lines, substations, and power and light distribution for industrial plants. Available at once. C-8648.

SOUND ENGINEER, 26, graduate E. E. One and one-half years recording engineer on talking motion pictures, 1½ years on audio amplifier design, remote control radio systems and public address systems. Thoroughly experienced on home recording apparatus. Available immediately. Location, New York and vicinity. C-4407.

CHINESE ELECTRICAL ENGINEER, Cornell graduate, M. M. E., G. E. test. Two years' public utility, nine years' power plant engineering experiences with leading American concerns, has great acquaintances among Chinese engineering circles, seeks connections with American manufacturers having interests in China. Location preferably, Shanghai, B-5548.

PROFESSOR OF ELECTRICAL ENGINEERING, 40, six years' successful experience teaching practically all branches electrical engineering, state school. Considerable experience power, telephone work. One year switchboard engineering department of Westinghouse. B. S. in E. E. and E. E. degrees. Prefer location, Rocky Mountain, Pacific Coast States. Available school year 1931-1932. C-5021.

ELECTRICAL, MECHANICAL ENGINEER, college graduate with wide practical experience in power plant work and industrial electrical equipment. Desires connection. Available immediately. B-2492.

ELECTRICAL-MECHANICAL ENGINEER employed by one of the leading consulting engineers for 13 years is now available. Experience covers design, construction and operation of high pressure steam turbine driven lectric generating stations and necessary high tension substations and transmission lines, and all phases of industrial engineering. C-8249.

ASSISTANT TO EXECUTIVE, electrical engineer, university graduate, 2 years' graduate work, 2 years' electrical instrument manufacturing and three years' public utility general testing experience. German fluent, reading knowledge of French, literary ability; engineering reports and correspondence. Pleasing personality, alert, industrious, reliable; excellent references. Wishes to relieve a busy executive. C-930.

ELECTRICAL ENGINEER, 1930 graduate, 25, single. Two years' drafting experience. Desires engineering work with opportunity for advancement. Location, immaterial. C-8437.

EXECUTIVE, production engineer, cost expert, cost accounts, budget control, practical, technical, commercial instruments, telephones, printing, machinery, pressed steel wave enamel, stainless steel, tunnel and galvanized. C-3241.

GRADUATE ELECTRICAL ENGINEER, 30. Two years' railroad shop and power plant experience, 4¼ years large eastern railroad electrical engineer's office drafting and design, appraisal electrical and power plant machinery, investigation and reports of engineering projects. Nineteen months electrician U. S. Shipping Board Diesel and Diesel-Electric motorships. Speak Spanish. C-8160.

ELECTRICAL ENGINEER, college graduate, A. I. T. Good character, married, 24. Pre-college experience: two years' middlewestern utilities as electrician's assistant; one year electrical repairs for self. Earned way through college and continuing now in repair business. Would like construction or central station installation work. Location anywhere. Available after June 15. C-8668.

ELECTRICAL ENGINEER, over 20 years' experience, design, construction and operation, power plants, distribution, substation and industrial installations of all kinds. Capable of taking charge either inside or outside or both and showing results. B-7034.

GRADUATE ELECTRICAL ENGINEER, with sound technical training who speaks Spanish readily and has wide technical experience including hydro-electric plant operation, distribution work and some steam experience. Desires responsible position with Latin American utility. B-4132.

ELECTRICAL ENGINEER, B. S., 1929, Westinghouse Student Course 1929-1930, with experience in meter engineering, desires place with public utility company in transmission, distribution or metering, or in development or research work. Will go anywhere. Would also consider engineering instruction job in technical school or college. C-8616.

GRADUATE ELECTRICAL ENGINEER, age 31, married. Eight years' experience including two years G. E. test, 1 year sales, 1 year valuation of lighting and telephone equipment and five years on electrical construction including estimating, layout work, and supervising installations. Desires a permanent connection with a future. B-9090.

ELECTRICAL ENGINEER, 35, technical education with 10 years' executive experience supervising both design and construction. Desires position as engineer in charge of design, or construction or as plant engineer. Location immaterial. C-8683.

SALES AND EXECUTIVE ENGINEER, electrically trained with experience in sales engineering, promotion and management. Would like to take an important part in progressive and high-grade organization. C-5431.

Membership

Transfers Recommended

The board of examiners, at its meetings of December 23, 1930, and January 20, 1931, recommended the following members for transfer to the grades of membership indicated. Any objection to these transfers should be filed at once with the National Secretary.

To Grade of Fellow

BROOKS, HERBERT B., Physicist, Chief of Electrical Instrument Section, Bureau of Standards, Washington, D. C.

HARDING, ARTHUR L., Asst. Elec. Engr., Electric Bond & Share Co., New York.

KELMAN, J. N., President and Manager, Kelman Elec. & Mfg. Co., Los Angeles, Calif.

MOORE, ERNEST E., Consulting Foreign Engineer, Electric Bond & Share Co., New York, N. Y.

STONE, EDMUND O., System Development Mgr., Duquesne Light Co., Pittsburgh, Pa.

To Grade of Member

ALDERMAN, HAYWOOD L., Assistant Engineer, Electric Bond & Share Co., New York.

BABCOCK, ROBERT O., Asst. Engr., Brooklyn Edison Co., Brooklyn, N. Y.

BAILEY, ROBERT C., System Relay Engr., Virginia Elec. & Pr. Co., Richmond, Va.

BENNISON, LIONEL C., Hobart District Engr., Hydro Electric Commission, Hobart, Tasmania.

BRACKETT, HAROLD H., Engr. of Toll Plant Extension and Transmission, N. J. Bell Telephone Co., Newark, N. J.

BRESSLER, JOHN W., Electrical Engineer, Voorhees, Gmelin & Walker, New York

BROOKMEYER, EDGAR W., Vice-President and Secretary, The Brown Brockmeyer Co. Inc., Dayton, Ohio.

BRUNDIGE, JOHN A., Sponsor Engineer, Electric Bond & Share Co., New York.

CHESNUT, FRANK T., Elec. Engr., Ajax Electrothermic Corp., Trenton, N. J.

COOLEY, GILBERT, Asst. Engr., Electric Bond & Share Co., New York.

COONEY, RICHARD T., Supt. of Elec. Const., United Engineers & Constructors, Inc., Philadelphia, Pa.

CREASER, ISAIAH, Elec. Engr., The Replitura Corp., Stamford, Conn.

DAVIDSON, ROSS W., Sponsor Engineer, Electric Bond & Share Co., New York.

FAULKNER, ARTHUR S., Mains Engr., Electricity Dept., Brisbane City Council, Queensland, Australia.

FERGUSON, RANDON, Asst. Engr., Investigation of Stresses in Track, University of Illinois, Urbana, Ill.

FINN, JAMES J., Supt., The Roland T. Oakes Co., Holyoke, Mass.

FRIEND, OTTO A., Telephone Engr., American Tel. & Tel. Co., New York.

FROEHLICH, FREDERICK H., President, The Froehlich & Emery Engg. Co., Toledo, Ohio.

GARDNER, MURRAY F., Asst. Prof. of Elec. Engg., Mass. Inst. of Technology, Cambridge, Mass.

GOULD, LAWRENCE E., President, Economy Elec. Devices Co., Chicago, Ill.

HOISINGTON, N. P., Vice-President, W. V. Pangborne & Co., Inc., Philadelphia, Pa.

HOLDEN, EDWARD A., Asst. Engr., Electric Bond & Share Co., New York.

JICKLING, ROBERT W., Transmission and Distribution Engr., Saskatchewan Power Commission, Regina, Sask., Canada.

KATES, WILLARD A., Development Engr., Corning Glass Works, Corning, N. Y.

KEMP, PHILIP, Head of School of Engg., The Polytechnic, London, England.

LANGDON, GLEN G., Engg. Dept., American Gas & Electric Co., New York.

MACMURCHY, HERBERT G., Asst. Engr., Electric Bond & Share Co., New York.

MANGELS, WALTER C., System Operator, Public Service Elec. & Gas. Co., Newark, N. J.

MOORE, CHARLES R., Member, Technical Staff, Bell Telephone Laboratories, Inc., New York.

MOTTER, HARRY W., Sales and Consulting Elec. Engr., York, Pa.

NEUBER, MAX, Experimental and Development Engr., Moto Meter Gauge & Equipment Co., Toledo, Ohio.

NOTT, GORDON E., Transmission and Protection Engr., Southern California Telephone Co., Los Angeles, Calif.

OSBORN, CHARLES F., Elec. Engr., Ralston Purina Co., St. Louis, Mo.

PAOLINO, SERAFINO, Electrical Designing Draftsman, Pacific Gas & Elec. Co., San Francisco, Calif.

PENMAN, ROY F., Asst. Engr., Electric Bond & Share Co., New York.

PERRIN, LOUIS M., Asst. Elec. Engr., Bureau of Engg., City of San Francisco, San Francisco, Calif.

RICHARDSON, RICHARD P., Asst. Protection Engr., Electricity Dept., Sydney, N. S. W. Australia.

SATTERTHWAITE, J. P., Transmission Maintenance Methods Supervisor, American Tel. & Tel. Co., New York.

SEELEY, ARTHUR P., Elec. Engr., Westcott & Mapes, Inc., New Haven, Conn.

SHAW, ALFRED E., Elec. Engg., Virginia Elec. & Power Co., Richmond, Va.

SILLS, HUBERT R., Asst. Engr., Canadian General Electric Co., Peterboro, Ont., Canada.

SMITH, JOHN A., Elec. Engr., Arthur D. Riley & Co., Ltd., Wellington, N. Z.

STYFF, EIVIND, Elec. Engr., Aktieselskapet Norsk Elektrisk & Brown Boveri, Oslo, Norway.

VAUGHAN, GEORGE W., Asst. Engr., Electric Bond & Share Co., New York.

WHITAKER, WILLIAM G. H., Chief Engr., N. J. Bell Telephone Co., Newark, N. J.

◆

Applications for Election

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before February 28, 1931.

Abas, J. A., Michigan College of Mining & Technology, Houghton, Mich.

Anderson, G. A., H. B. Squires Co., San Francisco, Calif.

Arapakis, G. H., (Member), New York Edison Co., New York, N. Y.

Arce, M. S., National Railways of Mexico, Chihuahua, Chih., Mexico

Arzadon, F. S., 27 West Superior St., Chicago, Ill.

Ashmead, H. E., American Tel. & Tel. Co., Cleveland, Ohio

Avary, S. A., General Electric Co., Schenectady, N. Y.

Avey, A. F., Niagara & Eastern Power Corp., Buffalo, N. Y.

Babb, M. A., General Electric Co., West Lynn, Mass.

Badgley, W. G., Jr., Public Service Elec. & Gas Co., Irvington, N. J.

Bagg, R. F., New York State, Watertown, N. Y.

Baker, A. E., Pennsylvania Railroad, New York, N. Y.

Baldwin, D. R., Aluminum Co. of America, Alcoa, Tenn.

Baltzar, J., Southern California Edison Co., Big Creek, Calif.

Barzilaski, P. M., N. Y. Navy Yard, Brooklyn, N. Y.

Bates, A. C., Purdue University, West Lafayette, Ind.

Beardsley, K. D., General Electric Co., Pittsfield, Mass.

Behm, J. H., General Electric Co., Schenectady, N. Y.

Bennett, G. R., Jr., 1559 Monterey Place, Mobile, Ala.

Berry, W. S., Underwriters' Laboratories, New York, N. Y.

Braum, C. M., City of Minneapolis, Minneapolis, Minn.

Brown, E. I., Cia. Hidroelectrica Guanajuantense, S. A., Mexico, D. F., Mex.

Bryant, F. R., Kent Owens Machine Co., Toledo, Ohio

Buehler, W. G., American Tel. & Tel. Co., Minneapolis, Minn.

Buel, K. F., Union Electric Light & Power Co., St. Louis, Mo.

Bukey, N. J., Union Gas & Electric Co., Cincinnati, Ohio

Bush, G. L., Teleregister Corp., New York, N. Y.

Cahoon, W. J., Houghton County Elec. Light Co., Houghton, Mich.

Caldwell, J., 3189 Grand Concourse, New York, N. Y.

Cameron, D. A., Public Service Co. of No. Illinois, Chicago, Ill.

Cameron, D. L., Skelly Oil Co., El Dorado, Kans.

Caparone, M. J., Rund Mfg. Co., Pittsburgh, Pa.

Carruth, H. B., Cupp Construction Co., Nashville, Ark.

Carter, B. H., Columbia Gas & Electric Co., Cincinnati, Ohio

Casper, C. L., American Tel. & Tel. Co., Nashville, Tenn.

Cedick, S. J., Cleveland Railway Co., Cleveland, Ohio

Clarendon, C. H., Jr., Weston Electrical Instrument Corp., Newark, N. J.

Clark, G. J., General Electric Co., Toledo, Ohio

Clark, M. C., Pennsylvania Railroad, Long Island City, N. Y.

Clark, W. R., Leeds & Northrup, Philadelphia, Pa.

Clarkson, W. G., Canadian Westinghouse Co., Hamilton, Ont., Can.

Coan, M., A. S. Riggs, New York, N. Y.

Colson, H. L., Westinghouse Elec. & Mfg. Co., Sharon, Pa.
(Applicant for re-election)

Coyle, W. A., Jr., 573 Hopkins St., Buffalo, N. Y.

Critchett, C. A., Ohio Bell Tel. Co., Dayton, Ohio

Crittendon, L. R., DuPont Ammonia Corp., Belle, W. Va.

Crosno, C. D., Iowa State College, Ames, Ia.

Cummings, H. B., Jr., Georgia Power Co., Atlanta, Ga.

Dapson, F. L., New York & Queens Elec. Lt. & Pr. Co., Flushing, N. Y.

Davis, K. C., General Electric Co., Toledo, Ohio

Demeros, A. G., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Dixon, I. H., Consolidated Gas Elec. Lt. & Pr. Co., Baltimore, Md.

Dorr, G., Toledo Edison Co., Toledo, Ohio

Doss, L. F., New Jersey Bell Tel. Co., Newark, N. J.

Duncan, D. C., Illinois Bell Telephone Co., Chicago, Ill.

Eastman, C. A., Pennsylvania Power & Light Co., Allentown, Pa.

Eckert, O. E., (Member), Board of Water & Electric Light Commissioners, Lansing, Mich.

Elg, G. W., New York Edison Co., New York, N. Y.

Estler, K. E., Westinghouse Lighting Institute, New York, N. Y.

Evans, O. D., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Ewart, J. N., Buffalo General Electric Co., Buffalo, N. Y.

Falconer, M. C., City of Tacoma, Hoodsport, Wash

Farrelly, J. W., Southwestern Bell Tel. Co., San Antonio, Tex.

Ferrick, J. H., American Tel. & Tel. Co., Pittsburgh, Pa.

Fishburne, C. L., Jr., University of South Carolina, Columbia, S. C.

Fisher, C. E., Bell Tel. Labs., New York, N. Y.

Flarida, H. R., Robbins & Myers, Springfield, Ohio

Flippin, A. W., Pacific Gas & Electric Co., Oakland, Calif.

Foley, J. A., General Electric Co., Toledo, Ohio

Forfa, J. S., United Elec. Service Co., New York, N. Y.

Foster, H. K., Dalton-Marsh Co., Danvers, Mass.

Franks, S. T., Canadian & General Finance Co., Ltd., Toronto, Ont., Can.

Freeland, F., Northwestern Electric Co., Portland, Ore.

Fuller, H. M., Philips Wire Co., Darlington, R. I.

Garrett, R. F., Western Electric Co., Kearny, N. J.

Geer, G. D., Texas Electric Service Co., Sweetwater, Tex.

Giddens, A. J., Cleveland Railway Co., Cleveland, Ohio

Gille, W. H., Minneaplis Honeywell Reg. Co., Minneapolis, Minn.

Gillis, J. D., University of Santa Clara, Santa Clara, Calif.

Glendinning, W., Brooklyn Edison Co., Brooklyn, N. Y.

Greenman, H. F., New England Public Service Co., Augusta, Me.

Greer, D. M., Westinghouse Elec. & Mfg. Co., Newark, N. J.

Guenthner, R. H., Northwestern Public Service Co., Yankton, S. D.

Gwathmey, L., General Electric Co., Schenectady, N. Y.

Hague, C. W., General Electric Co., Cleveland, Ohio

Haldeman, W. F., Motor Products Corp., Detroit, Mich.

Hallar, E., United Electric Light Co., Springfield, Mass.

Hamilton, J. A., Bell Tel. Co. of Pa., Pittsburgh, Pa.

Hammer, K. E., Bell Telephone Laboratories, New York, N. Y.

Hansen, P. B., (Member), Graybar Electric Co., Inc., Minneapolis, Minn.

Harrington, J. R., (Member), Howe Signal Co.; Howe Mfg. Co., Chicago, Ill.

Hartig, O., Eagle Electric Mfg. Co., Brooklyn, N. Y.

Haspel, G. K., (Member), Independent Sales & Engineering Co. Ltd., Vancouver, B. C., Can.

Hazelton, R. M., 470 E. 161st St., New York, N. Y.

Heine, T. C., New York Tel. Co., New York, N. Y.

Hellwarth, A. R., University of Michigan, Ann Arbor, Mich.

Helwig, W. F., (Member), Texas Technological College, Lubbock, Tex.

Hendricks, W., Allis-Chalmers Mfg. Co., Pittsburgh, Pa.

Henrikson, F. W., General Electric Co., New York, N. Y.

Hentzen, H. K., Southwestern Bell Tel. Co., Kansas City, Mo.

Hindman, B. W., Public Service Co. of No. Ill., Maywood, Ill.

Hollingshead, E. C., Westinghouse Elec. & Mfg. Co., Sharon, Pa.

Horsfall, J. D., Ohio Bell Tel. Co., Cleveland, Ohio

Horvath, J. J., Electric Bond & Share Co., New York, N. Y.

Hoshiai, M., c/o Consulate General of Japan, New York, N. Y.

Hrubec, T. T., General Cable Corp., Perth Amboy, N. J.

Hultberg, C. A., Transformer Corp. of America, Chicago, Ill.

Huskin, F. P., Carolina Power & Light Co., Asheville, N. C.

Hynes, F. B., (Fellow), Crocker Wheeler Elec. Mfg. Co., Amper, N. J.

Irvine, G. L., General Electric Co., Schenectady, N. Y.

Ivanoff, N. A., D. L. & W. Railroad Co., Hoboken, N. J.

Jacob, F. N., RCA Victor Co., Inc., Mt. Lebanon, Pa.

Janone, V., General Cable Corp., Rome, N. Y.

Jasper, H. N., Jr., American Tel. & Tel. Co., Cleveland, Ohio

Jenkins, S. P., Utah Copper Co., Bingham Canyon, Utah

Jeremiah, W. S., Pennsylvania Power & Light Co., Hazleton, Pa.

Jivatode, R. S., Carolina Pr. & Lt. Co., Raleigh, No. Car.

Jones, H. H., Brooklyn Edison Co., Brooklyn, N. Y.

Jones, T. B., Ohio Brass Co., Dallas, Tex.

Joy, C. H., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Judd, R. S., Southern New England Tel. Co., New Haven, Conn.

Judkins, A., 37 Rolfe St., Auburn, R. I.

Keachie, J. H., General Electric Co., Schenectady, N. Y.

Kemper, G. W., Westinghouse Elec. & Mfg. Co., Sharon, Pa.

Kennard, W., 210 Pierce Hall, Cambridge, Mass.

Kerigan, F. A., Pennsylvania Railroad Co., Altoona, Pa.

Kerley, V. E., Oregon State College, Corvallis, Ore.

Killingsworth, H. M., General Electric Co., Philadelphia, Pa.

Kimball, G. S., Stanford University, Stanford University, Calif.

King, W. L., Northwestern Bell Tel. Co., Rapid City, So. Dak.

Kinney, A. B., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Kissner, E., Little & Branch, New York, N. Y.

Klein, H., 687 Lexington Ave., New York, N. Y.

Knapp, E. W., Shawinigan Water & Power Co., Montreal, Que., Can.

Knapp, N., Jr., Bell Tel. Labs., Inc., New York, N. Y.

Knerr, L. R., Pacific Gas & Electric Co., Oakland, Calif.

Kohli, W. W., Standard Sanitary Mfg. Co., Tiffin, Ohio

Korba, A. A., Northern States Power Co., St. Paul, Minn.

Kramer, A., Puget Sound Pr. & Lt. Co., Seattle, Wash.

Lafranchi, V., City Light Dept. of Seattle, Seattle, Wash.

Langford, J. W., Jr., General Electric Co., Philadelphia, Pa.

Larson, H. O., Western Electric Co., Kearny, N. J.

Leary, J. F., Trinidad Leaseholds, Ltd., Trinidad, B. W. I.

Leary, J. R., Bell Tel. Co. of Pa., Pittsburgh, Pa.

Ledermann, W., Sargent & Lundy, Chicago, Ill.

Leithead, R. C., Mass. Inst. of Technology, Cambridge, Mass.

Lewis, F. A., "Electrical Engineering," 33 W. 39th St., New York, N. Y.

Lindell, C. H., Union Gas & Electric Co., Cincinnati, Ohio

Linn, G. J., Commonwealth Edison Co., Chicago, Ill.

Linton, E. W., New York Tel. Co., Brooklyn, N. Y.

Louttit, W. C., (Member), United Railways of Havana, Havana, Cuba

Lucas, E. L., 3959-15th Ave., N. E., Seattle, Wash.

Lucas, F. L., City of Toledo, Toledo, Ohio

Ludlam, G., Western Electric Co., Pittsburgh, Pa.

Mabson, E. B., Louisiana Power & Light Co., Algiers, La.

Mahan, K. C., General Electric Co., Schenectady, N. Y.

Marine, E. H., Bureau of Power & Light of Los Angeles, Saugus, Calif.

Martin, H. L., Westinghouse Elec. & Mfg. Co., Chicago, Ill.

Marx, W. F., Allis-Chalmers Mfg. Co., Pittsburgh, Pa.

Mathewson, H. G., Southwestern Bell Tel. Co., Dallas, Tex.

National Treasurer

W. I. SLICHTER

National Secretary

F. L. HUTCHINSON

General Counsel

PARKER & AARON
30 Broad Street, New York

Local Honorary Secretaries

T. J. Fleming, Calle B. Mitre 519, Buenos Aires, Argentina, S. A.
H. W. Flashman, Aus. Westinghouse Elec. Co., Ltd., Cathcart House, 11 Castlereagh St., Sydney, N. S. W., Australia.
F. M. Servos, Rio de Janiero Tramways, Light & Power Co., Rio de Janeiro, Brazil.
A. P. M. Fleming, Metropolitan Vickers Elec. Co., Trafford Park, Manchester, England.
A. S. Garfield, 173 Boulevard Haussmann, Paris 8 E., France.
Renzo Norsa, Via Caravaggio 1, Milano 25, Italy.
P. H. Powell, Canterbury College, Christchurch, New Zealand.
M. A. Chatelain, Polytechnical Institute, Apt. 27, Leningrad, Sosnowka 1/3, U. S. S. R.
Axel F. Enstrom, 24a Ingeniorsvetenskrapsakademien, Stockholm, 5 Sweden.
W. Eldson-Dew, P. O. Box 4563 Johannesburg, Transvaal, Africa.

INSTITUTE COMMITTEES

(A list of the personnel of Institute committees may be found in the January issue of ELECTRICAL ENGINEERING)

General Standing Committees and Chairmen

Executive	W. S. Lee
Finance	C. E. Stephens
Meetings and Papers	A. E. Knowlton
Publication	W. S. Gorsuch
Coordination of Institute Activities	H. P. Charlesworth
Board of Examiners	H. W. Drake
Sections	Everett S. Lee
Student Branches	W. H. Timbie
Membership	J. Allen Johnson
Headquarters	R. H. Tapscott
Law	E. B. Meyer
Public Policy	Bancroft Gherardi
Standards	F. D. Newbury
Edison Medal	D. C. Jackson
Lamme Medal	Charles F. Scott
Code of Principles of Professional Conduct	F. B. Jewett
Award of Institute Prizes	A. E. Knowlton
Safety Codes	A. W. Berresford
Engineering Profession	H. A. Kidder
Columbia University Scholarships	W. I. Slichter
Popular Science Award	A. E. Knowlton
Advisory Committee to the Museum of Science and Industry in the City of New York	J. P. Jackson

Technical Committees and Chairmen

Automatic Stations	F. Zogbaum
Communication	G. A. Kositzky
Education	W. R. Work
Electrical Machinery	Philip L. Alger
Electric Welding	P. P. Alexander
Electrochemistry and Electrometallurgy	P. H. Brace
Electrophysics	O. E. Buckley
General Power Applications	C. W. Drake
Instruments and Measurements	E. J. Rutan
Applications to Iron and Steel Production	A. C. Cummins

Production and Application of Light	George S. Merrill
Applications to Marine Work	R. A. Beekman
Applications to Mining Work	Carl Lee
Power Generation	F. A. Allner
Power Transmission and Distribution	P. H. Chase
Protective Devices	Raymond Bailey
Research	L. W. Chubb
Transportation	Sidney Withington

INSTITUTE REPRESENTATIVES

(The Institute is represented on the following bodies; the names of the representatives may be found in the January issue of ELECTRICAL ENGINEERING)

Aeronautical Radio Research, Liaison Committee on
Alfred Noble Prize Committee, A. S. C. E.
American Association for the Advancement of Science, Council
American Bureau of Welding
American Committee on Electrolysis
American Engineering Council Assembly
American Marine Standards Committee
American Standards Association
American Year Book, Advisory Board
Charles A. Coffin Fellowship and Research Fund Committee
Committee of Apparatus Makers and Users, National Research Council
Committee on Elimination of Fatigue, Society of Industrial Engineers
Committee on Heat Transmission, National Research Council
The Engineering Foundation
Engineering Societies Monographs Committee
Hoover Medal Committee
John Fritz Medal Board of Award
Joint Committee on Welded Rail Joints
Joint Conference Committee of Four Founder Societies
Library Board, United Engineering Trustees, Inc.
National Fire Protection Association, Electrical Committee
National Fire Waste Council
National Research Council, Engineering Division
National Safety Council, Electrical Committee of A. S. S. E.—Engineering Section
Radio Advisory Committee, Bureau of Standards
United Engineering Trustees, Inc.
U. S. National Committee of the International Commission on Illumination
U. S. National Committee of the International Electrotechnical Commission
Washington Award, Commission of

GEOGRAPHICAL DISTRICT EXECUTIVE COMMITTEES

District	Chairman (Vice-President, A. I. E. E.)	Secretary (District Secretary)
No. 1—North Eastern	I. E. Moultrop, Edison Elec. Illum. Co., 39 Boylston St., Boston	A. C. Stevens, General Electric Co., Schenectady
No. 2—Middle Eastern	E. C. Stone, Duquesne Light Co., 435 Sixth Ave., Pittsburgh	J. A. Cadwallader, Bell Tel. Co. of Pa., 416 Seventh Ave, Pittsburgh
No. 3—New York City	H. P. Charlesworth, 463 West St., New York	C. R. Jones, Westinghouse E. & M. Co., 150 Broadway, New York
No. 4—Southern	W. S. Rodman, Box 675, University, Va.	J. S. Miller, Jr., Box 12, University, Va.
No. 5—Great Lakes	T. N. Lacy, Mich. Bell Tel. Co., 1365 Cass Ave., Detroit	A. G. Dewars, No. States Pr. Co., 15 S. 15th St., Minneapolis
No. 6—North Central	Herbert S. Evans, University of Colorado, Boulder, Colo.	M. S. Coover, University of Colorado, Boulder, Colo.
No. 7—South West	G. C. Shaad, University of Kansas, Lawrence, Kans.	Robert W. Warner, University of Kansas, Lawrence, Kans.
No. 8—Pacific	C. E. Fleager, Pac. Tel. & Tel. Co., 140 New Montgomery St., San Francisco	H. W. Hitchcock, 1050 Telephone Bldg., 740 South Olive St., Los Angeles
No. 9—North West	H. V. Carpenter, State College of Washington, Pullman, Wash.	R. D. Sloan, State College of Washington, Pullman, Wash.
No. 10—Canada	C. E. Sisson, Canadian Gen. Elec. Co., 1025 Lansdowne Ave., Toronto, Ont.	W. L. Amos, Hydro-Elec. Pr. Com., 190 University Ave., Toronto, Ont.

Note: Each District Executive Committee includes the chairmen and secretaries of all Sections within the District and the chairman of the District Committee on Student Activities.

LOCAL SECTIONS OF THE INSTITUTE

Name	District	Chairman	Secretary	Secretary's Address
Akron	2	H. C. Paiste	Alvin P. Regal	Phila. Rubber Works Co., Akron, Ohio
Atlanta	4	H. C. Uhl	O. O. Rae	Westinghouse E. & M. Co., Atlanta, Ga.
Baltimore	2	W. B. Kouwenhoven	J. Wells	Western Elec. Co., 25 Broening Rd., Baltimore, Md.
Birmingham	4		O. E. Charlton	Allied Engineers, Inc., Birmingham, Ala.
Boston	1	J. P. Kobrock	G. J. Crowdes	Simplex Wire & Cable Co., Sidney St., Cambridge, Mass.
Chicago	5	F. H. Lane	L. R. Mapes	Ill. Bell Tel. Co., 212 W. Washington St., Chicago, Ill.
Cincinnati	2	T. C. Reed	L. L. Bosch	Columbia Eng. & Mgt. Corp., 314 West 4th St., Cincinnati, Ohio
Cleveland	2	F. W. Braund	John M. Smith	Nela Park, Cleveland, Ohio
Columbus	2	C. D. Price	K. Y. Tang	Ohio State University, Columbus, Ohio
Connecticut	1	Samuel Ferguson	R. G. Warner	Yale Univ., 10 Hillhouse Ave., New Haven, Conn.
Dallas	7	L. T. Blaisdell	G. A. Dyer	Southwestern Bell Tel. Co., Dallas, Texas
Denver	6	R. B. Bonney	N. R. Love	807 Tramway Bldg., Denver, Colo.
Detroit-Ann Arbor	5	LeRoy Braisted	J. J. Shoemaker	Detroit Edison Co., 2000-2nd Ave., Detroit, Mich.
Erie	2	G. R. McDonald	G. I. LeBaron	General Elec. Co., Erie, Pa.
Fort Wayne	5	W. J. Morrill	C. M. Summers	General Elec. Co., Fort Wayne, Ind.
Houston	7	C. D. Farman	Hezzie Clark	Humble Pipe Line Co., Drawer, 1761, Houston, Texas
Indianapolis-Laf	5	E. G. Ralston	C. E. Dutton	15 W. New York St., Room 222, Indianapolis, Ind.
Iowa	5	J. K. McNeely	H. B. Hoffhaus	Des Moines El. Lt. Co., 312-6th Ave., Des Moines, Iowa
Ithaca	1	W. C. Ballard, Jr.	W. E. Meserve	614 E. Buffalo St., Ithaca, N. Y.

LOCAL SECTIONS OF THE INSTITUTE—*Continued*

Name	District	Chairman	Secretary	Secretary's Address
Kansas City	7	J. S. Palmer	Richard M. Ryan	510 Dwight Bldg., Kansas City, Mo.
Lehigh Valley	2	W. M. Harbaugh	J. H. Diefenderfer	Penn. Pr. & Lt. Co., Hazleton, Pa.
Los Angeles	8	H. W. Hitchcock	Philip S. Biegler	3551 University Ave., Los Angeles, Calif.
Louisville	4	James Clark, Jr	Philip P. Ash	L. & N. R. R. Bldg., 9th and Broadway Ave., Louisville, Ky.
Lynn	1	A. L. Ellis	W. K. Dickinson	General Elec. Co., West Lynn Works, Lynn, Mass.
Madison	5	L. C. Larson	G. F. Tracy	Elec. Lab. Bldg., Univ. of Wisconsin, Madison, Wis.
Memphis	4	M. Eldredge	W. A. Gentry	Memphis Pr. & Lt. Co., Memphis, Tenn.
Mexico	3	B. E. Arias	L. Castro, Jr	Departamento Electricidad y Telegrafos, Ferrocarriles Nacionales de Mexico, Mexico, D. F.
Milwaukee	5	F. A. Kartak	I. L. Illing	Milwaukee El. Ry. & Lt. Co., 380 Pub. Serv. Bldg., Milwaukee, Wis.
Minnesota	5	D. K. Lewis	H. J. Pierce	Northwestern Bell Tel. Co., Minneapolis, Minn.
Nebraska	6	W. O. Jacobi	A. L. Turner	1112 Telephone Bldg., Omaha, Nebraska
New York	3	J. B. Bassett	C. R Jones	Westinghouse E. & M. Co., 150 Broadway, New York, N. Y.
Niagara Frontier	1	E. S. Bundy	G. W. Eighmy	General Elec. Co., 1100 Elec. Bldg., Buffalo, N. Y.
North Carolina	4	J. H. Paget	F. C. DeWeese	Carolina Pr. & Lt. Co., Raleigh, N. C.
Oklahoma City	7	F. J. Meyer	C. E. Bathe	Oklahoma Gas & Elec. Co., Oklahoma City, Okla.
Philadelphia	2	D. H. Kelly	J. L. MacBurney	El. St. Bat. Co., 1955 Hunting Park Ave., Phila., Pa.
Pittsburgh	2	C. T. Sinclair	F. A. Connor	General Elec. Co., 1309 Oliver Bldg., Pittsburgh, Pa.
Pittsfield	1	C. H. Kline	L. H. Burnham	General Electric Co., Pittsfield, Mass.
Portland, Ore	9	A. H. Kreul	C. W. Fick	General Electric Co., Portland, Oregon
Providence	1	J. W. Young	O. W. Briden	Blackstone Valley G. & E. Co., 231 Main St., Pawtucket, R. I.
Rochester	1	Harvey J. Klumb	F. C. Young	Stromberg-Carlson Co., 100 Carlson Rd., Rochester, N. Y.
St. Louis	7	C. B. Fall	E. A. Forkner	Wagner Elec. Corp., 6400 Plymouth Ave., St. Louis, Mo.
San Antonio	7	D. W. Flowers	E. Bissett	San Antonio P. S. Co., 201 N. St., Mary St., San Antonio, Texas
San Francisco	8	P. B. Garrett	E. F. Maryatt	Pacific G. & E. Co., 245 Market St., San Francisco, Calif.
Saskatchewan	10	W. T. Hunt	A. B. Coward	Light and Power Dept., Regina, Sask., Canada
Schenectady	1	E. S. Henningsen	E. P. Nelson	D. C. Eng. Dept. General Elec. Co., Schenectady, N. Y.
Seattle	9	C. E. Carey	Philip D. Jennings	5560 Stuart Bldg., Seattle, Wash.
Sharon	2	S. S. Cook	R. M. Field	Westinghouse E. & M. Co., Sharon, Pa.
Southern Virginia	4	J. H. Berry	Cecil Gray	Westinghouse E. & M. Co., 912 El. Bldg., Richmond, Va.
Spokane	9	Loren A. Traub	C. F. Norberg	Washington Water Pr. Co., Spokane, Wash.
Springfield, Mass	1	J. N. Alberti	L. C. Packer	Westinghouse E. & M. Co., Page Blvd., Springfield, Mass.
Syracuse	1	F. E. Verdin	Charles W. Henderson	504 University Pl., Syracuse, N. Y.
Toledo	2	F. H. Dubs	Max Neuber	1257 Fernwood Ave., Toledo, Ohio
Toronto	10	D. A. McKenzie	G. D. Floyd	Hydro El. Pr. Comm., 190 Univ. Ave., Toronto, Ont.
Urbana	5	C. E. Skroder	W. J. Putnam	123 Mat. Test. Lab. Univ. of Illinois, Urbana, Ill.
Utah	9	L. B. Fuller	Paul Ranson	Utah Apex Mining Co., Bingham Canyon, Utah
Vancouver	10	H. Vickers	C. Arnott	B. C. E. Ry. Co., Ltd., 425 Carrall St., Vancouver, B. C.
Washington	2	George W. Vinal	J. L. Carr	General Elec. Co., 800-15th St., N. W., Washington, D. C.
Worcester	1	J. K. Oldham	R. P. Bullen	General Elec. Co., Worcester, Mass.

Industrial Notes

South American Agent for Ohio Brass Company.—The Ohio Brass Company, Mansfield, Ohio, announces the appointment of Pirelli S/A, with offices in Rio de Janeiro and Sao Paulo, as Brazilian agent for that company in South America. Pirelli S/A, a branch of the Pirelli Company of Italy, large manufacturers of cables, chemicals, rubber goods, etc. maintains an extensive selling organization throughout Brazil.

General Electric Orders.—Orders received by the General Electric Company during the year 1930 amounted to $341,820,312, compared with $445,802,519 for 1929, a decrease of 23 per cent, President Gerard Swope has announced. Orders for the final quarter of 1930 amounted to $74,168,480, compared with $108,398,049 for the last quarter of 1929, a decrease of 32 per cent. As a result of the transfer of radio set and tube business, outlined in the company's 1929 annual report, orders received in 1930 do not include radio sets and tubes, except orders received for the new General Electric radios introduced in the latter part of the year.

U. S. Leads in Radio Exports.—According to a recent announcement from the Department of Commerce in Washington, more than 24,000,000 radio sets are in use throughout the world today, 45% being in the United States. Socket power sets account for 52% of the total number of sets in use in North America. In the majority of cases, outside of the United States and Canada, the cost of broadcasting is paid by a system of license fees levied on the sets in use, and these fees range from as low as thirty-nine cents in France to as high as $44 per set in Turkey. The average license fee, however, runs between $3 and $4. The United States is the world's largest exporter.

A New High Voltage Testing Set.—A highly accurate testing set of unusually flexible design, the AmerTran Type TS-15A, has been developed by by the American Transformer Company, 180 Emmet Street, Newark, N. J. This apparatus is ideally suited for light testing in either the factory or laboratory where potentials from 500 to 20,000 volts at 1 kv-a. are required. It is applicable in making accurate dielectric strength measurements on materials such as paper, tape, compound, varnished cambric, condensers, and insulation in small apparatus. The new AmerTran testing set operates from standard 110-volt, 60-cycle circuits and contains a special air-cooled testing transformer with a four-section secondary winding which permits of obtaining three different voltages at full output—5,000, 10,000 and 20,000. In addition the equipment includes a wire-wound potentiometer for adjusting the voltage to any value between zero and maximum, the exact value being indicated at all times by a precision double-range voltmeter connected to a special winding on the transformer. For protection against damage due to overload a quick-acting circuit breaker is provided. The unit is completely housed in a compact metal case on the front of which is mounted a Bakelite panel containing all operating controls.

Trade Literature

Linemen's Tools.—Bulletin 30, 68 pp. Describes a complete line of tools, belts, etc., for linemen and other electrical workers. Mathias Klein & Sons, 3200 Belmont Ave., Chicago.

Neon Glow Lamps.—Folders (2). Describe the characteristics and uses of standard neon glow lamps. General Electric Vapor Lamp Company, Hoboken, N. J.

Steam Turbines.—Bulletins GEA 1011B and 1080A, each 12 pages. Describe the design and construction of turbines for isolated plants and central stations. General Electric Company, Schenectady, N. Y.

Electroplating Aluminum.—Booklet, 36 pp., "Electroplating Aluminum." Describes the process of chromium plating and nickelplating of aluminum and alloys. Aluminum Company of America, Oliver Building, Pittsburgh.

Micarta.—Bulletin 1686-A, 16 pp., "Micarta in the Central Station." Describes Micarta insulation for power houses and substations, insulating bus bars and connections, and other applications. Westinghouse Electric & Mfg. Company, East Pittsburgh.

Test-Signal Generator.—Catalog supplement F-200, 4 pp. Describes type 404 test-signal generator for use in comparing performances of radio receivers, or of one receiver under various conditions. This apparatus has been designed with the requirement of service testing in mind. General Radio Company, Cambridge (A), Mass.

Direct-Current Volt-Ohmmeter.—Supplement 3 to Bulletin 100. Describes a new instrument, type PD, direct-current volt-ohmmeter, which may be used for continuity testing, as a direct reading ohmmeter, or for reading voltages up to 600 volts, direct current. It is recommended by the manufacturer particularly for radio testing. Roller-Smith Company, 12 Park Place, New York.

Quadrant Electrometer.—Bulletin 330, 4 pp. Describes the "Compton quadrant electrometer." This instrument, according to the manufacturer, is probably the most delicate electrostatic instrument available, and due to its simplicity and high sensitiveness it has been widely used during the past few years in much of the best research work involving accurate electrostatic measurements. The Rubicon Company, 29 No. 6th Street, Philadelphia.

Rossman Speed Control.—Bulletin 1151, 12 pp. Describes the Rossman system of adjustable speed control which involves a method of controlling the speed of a given alternating-current drive machine over a wide speed range. It is being used with particular success for operating auxiliary equipment in large power plants. Allis-Chalmers Manufacturing Company, Milwaukee.

Lighting Panels.—Bulletin 12 pp. Describes the new "Superba" lighting panel, which is a revolutionary attempt to give attractive form to this equipment and get away from the staid straight lines of the conventional type at the same time. A more important feature is the greater flexibility and scientific design of the board from electrical and mechanical standpoints. Changes of circuit connections for both voltage and phase may be made readily without removing the door and trim or disturbing the wiring connections. These panels are composed of Bakelite units that can be furnished in a variety of colors to match background color schemes. Bull Dog Electric Products Company, 7610 Jos. Campau Avenue, Detroit.

Electric Heating Equipment.—Catalog 247, 100 pp. Describes Westinghouse industrial heating equipment and includes operating data, charts, and tables. The catalog contains definitions of terms relating to heat treatment operations, tables for determining furnace sizes and operating costs, descriptions of different furnaces, a section devoted to installation photographs, and specifications for industrial heating appliances such as air heaters, electric glue pots, electric snow melters for track switches, and oil immersion heaters. The last section of the publication consists of a control section describing magnetic controllers, push button stations, furnace transformers, thermometers, thermostats, pyrometers, etc., making this a comprehensive and complete publication on the subject of industrial heating. Westinghouse Electric & Mfg. Company, East Pittsburgh.

Industrial Notes 252

The Edison Medal for 1930 was presented January 28 to Dr. Frank Conrad by W. S. Lee, president of the Institute, following a eulogy effectively delivered by Dr. Chas. F. Scott, past-president and 1929 Edison medalist. *(See page 216)*

◆

Karl Taylor Compton, president of the Massachusetts Institute of Technology, characterized the electron as mankind's most nimble and effective servant in his demonstration lecture at one of the Institute's winter convention sessions. Dr. Compton did not attempt to reveal anything new and startling concerning the electron, but he did outline rather comprehensively the present status of scientific understanding of that most minute and highly animated particle of matter. *(See page 192)*

Protective relays and related automatic devices are correctly accredited with having done much to make possible long distance power transmission and to facilitate the handling of the great electric power concentrations required to meet ever-growing demands. Everett E. George describes the reactance relay installation of the Tennessee Electric Power Company, one of the first and most extensive applications of this relatively new device. Operating experiences are outlined in order that others may profit thereby. *(See page 205)*

◆

Some of the mysteries of electrical porcelain are reduced to a far less serious proportion by a brief discussion of chemistry, materials, and manufacturing methods given by H. M. Kraner. *(See page 209)*

Farley Granger Clark (A '01; M '12; F '13) is the ardent proponent of a rather comprehensive plan for improving the operating economies of electric power systems through definite efforts to provide an outlet for "surplus" power. Mr. Clark suggests that surplus power available from existing generating stations at other than peak-load periods can well be absorbed in various industrial and particularly electrolytic processes involved in the manufacture of many commodities, including fuel gas. Mr. Clark graduated from Cornell University in mechanical engineering, class of '94; from 1897 until 1902 he was with the Metropolitan Street Railway Company (N. Y.); 1903-4 with Westinghouse, Church, Kerr & Company (N. Y.); 1905-10 with the Pennsylvania Railroad; 1911 with the Westinghouse Company; 1912-22 chief engineer of the Toronto (Canada) Power Company and affiliates. Since 1923 he has been in private consulting practise. *(See page 197)*

◆

Another phase of the cooperative work of the communication and the electric service utilities in the interest of improved service to customers, revolves around the joint use of poles for the lines of the two utilities. J. C. Martin of the Middle West Utilities Company, and H. L. Huber of the American Telephone and Telegraph Company, each a transmission authority in his own field, have jointly produced a comprehensive outline of the present situation and current trends as regard cooperative work on joint pole use. *(See page 203)*

◆

The winter convention technical sessions with their wealth of material as represented by some fifty papers are comprehensively "covered" in ten news items. Some of the extensive discussion at four of the sessions is summarized; some further discussions will be presented in a subsequent issue. *(See pages 216-228)*

One of the most interesting factors influencing the trend of development of large electric generators, synchronous condensers, and similar rotating equipment, is the advent of hydrogen gas as a cooling medium. M. D. Ross, associated with the development of this type of equipment for the Westinghouse company, describes some of the problems and outlines some of the possibilities. *(See page 211)*

Pittsburgh, Pa., where the American Institute of Electrical Engineers will convene March 11-13, 1931, for a regular meeting of the Middle Eastern District (No. 2). For the news story of this meeting see the April issue of ELECTRICAL ENGINEERING

NOISE REDUCTION is being aggressively pushed from many different angles. R. B. GEORGE of the Westinghouse company describes experiments in controlling and reducing unpleasant noises emanating from power transformers and makes useful suggestions. *(See page 194)*

◆

TRAFFIC CONTROL, a vexing problem affecting an ever-increasing percentage of the general public, bids fair to be simplified greatly through ingenious applications of that most versatile device, the electron tube. R. C. HITCHCOCK, Westinghouse research engineer, describes some successful practical experiments in the use of light beams to operate traffic signals. *(See page 182)*

◆

WITH THE RECENT announcement of the Pennsylvania Railroad that it would proceed at once to complete the electrification of its main lines between New York City and Washington, D. C., and the announcement of electrification projects contemplated by other large railway systems, the question of railway electrification is assuming ever greater importance in engineering and economic circles. EDWARD L. MORELAND, well known consulting engineer and partner in the firm of Jackson & Moreland, Boston, who personally supervised the most important phases of the recently completed extensive electrification of the Lackawanna suburban lines serving New York City and New Jersey territory, discusses the important features of the project, several of which have established new precedents in the art. *(See page 185)*

◆

WILLIAM STATES LEE (A '04; M '03; F '13) active, competent, and aggressive president of the Institute, answers in detail a lengthy telegram from the Honorable Gifford Pinchot, governor of the commonwealth of Pennsylvania. In his letter, President Lee corrects certain misunderstandings which were evidenced by the telegram which Governor Pinchot sent under date of January 28 addressed jointly to President Lee and the winter convention assemblage of the Institute. *(See page 215)*

FOR THE FIRST TIME in so comprehensive a manner, the present trends in telephone and power practises as they affect inductive coordination are set forth, so that all who are interested may know something of the more important factors underlying the important engineering cooperative efforts between the communication and the electric service communities. W. H. HARRISON, American Telephone and Telegraph Company authority on the subject, and A. E. SILVER of the Electric Bond & Share Company representing the electric service utilities, not only are well qualified to discuss the subject but represent also tremendous aggregations of engineering ability. *(See page 176)*

◆

WILLIAM J. FOSTER of Schenectady, N. Y., has been awarded the Institute's Lamme medal which will be presented during the summer convention at Asheville, N. C., June 22-26, 1931. Dr. Foster receives the award "for his contributions to the design of rotating alternating-current machinery." *(See page 229)*

Telephone and Power Practises As They Affect Inductive Coordination

Proper coordination of parallel power and telephone circuits to control the noise induced in the latter is one of the oldest and most important problems requiring the joint consideration of power and telephone companies throughout the United States. Progress in the development of the telephone and power industries to meet growth and improve service, has an important influence on problems of coordination. Important trends and their influence are summarized in this paper.

By W. H. Harrison *and* *A. E. Silver*
Member A. I. E. E. — Fellow A. I. E. E.
American Tel. and Tel. Company, New York — Electric Bond & Share Co., New York

THE MANY important benefits resulting from the cooperative handling of questions arising from the proximity of the lines of the telephone and electric power systems of the United States are emphasized by the extent and the rapid growth of these two industries. Such a rate of growth (see accompanying illustrations) necessarily brings with it many cases of physical proximity where, because of the widely different characteristics of the circuits involved, difficulties might arise. The necessity for active study of the coordination of the different systems and for the current handling of large numbers of individual situations will continue for a long time to come.

In approaching the technical phases of the subject of coordination it seems well to emphasize the fact that, after all, the power and telephone companies serve essentially the same customers, and thus it is essential that both services be rendered in the most economical manner. Each utility, therefore, should construct its plant with full regard for the plans and facilities of the other.

The Joint General Committee of the National Electric Light Association and the Bell Telephone System has recommended principles and practises which recognize these fundamental factors and which point the way to the practical handling of each type of situation. In effect, each individual situation is contemplated to be worked out on the basis of the best over-all engineering solution, just as if both utilities were under one management. Without this basis of procedure it is hard to visualize how, with the service density of both utilities steadily mounting and with both the services rapidly extending into new territory, it would be possible to carry on these extensions in the present orderly fashion.

In the following are outlined some of the more important developments in the telephone and power industries, together with their effects upon coordination problems.

Perhaps the most important of these developments in both the power and telephone fields have to do with constant improvement in the quality of service afforded to customers. This trend is exemplified in the power system by fewer service interruptions, better voltage regulation, and better frequency regulation. In the telephone system this progress is marked primarily by the generally improved characteristics of transmitted speech and faster and more reliable service; secondarily, by a tremendous extension and widened scope of direct-connected voice communication channels.

In the telephone system the improvement in standards of service, if considered by itself, tends to increase the noticeability of inductive effects from outside sources. Similarly, increases in the extent of service and speed of completing calls have led to increased reliance on prompt telephone communication, tending to increase the importance of avoiding interruptions. Five years ago the average interval of time between the placing of a long distance toll call by a subscriber and the commencing of the conversation was 7½ minutes; at the present time it is a little less than 2½ minutes.

The improvement of service has been associated with a particularly rapid growth of very "long haul" telephone business and a consequent increase in the average length of telephone circuits used for interurban and long distance work. In the period 1925-29, while telephone toll business as a whole increased 59 per cent, New York-Chicago business increased 170 per cent and the combined Chicago and New York business to Los Angeles and San Francisco, 380 per cent. From the standpoint of coordination with other electric circuits the very long telephone circuit offers a more difficult problem than the circuit of moderate length because of the cumulative effect of exposures in different sections.

In the power industry one of the most important items in the improvement of service has been the steady decrease in the number of service interruptions. This has

---

From "Trends in Telephone and Power Practise as Affecting Coordination," (No. 31-21) presented at the A. I. E. E. winter convention, January 26-30, 1931, as Part 1 of a symposium on coordination of power and telephone plant.

been brought about mainly by better standards of construction including more systematic mechanical and electrical arrangement of circuits and apparatus, and increased numbers of circuits and sources of supply. While the increasing numbers of interconnecting and other types of lines bring new conditions requiring coordination of power and telephone plants, improved construction and increased security of circuits and apparatus have a definitely beneficial effect upon matters of coordination by reducing the number of abnormal conditions of operation. Better voltage regulation and certain accompanying factors which definitely aid coordination include better balance of currents in the separate phases of the circuits and more effective arrangements minimizing the tendency of currents to flow in the earth.

While in some respects the extent and rapid growth of the two utilities and the improvement of service standards have tended to increase the importance and the difficulties of coordination work, these adverse tendencies have been offset by beneficial effects of improvements in plant design and construction and by the cooperative endeavor which has been carried on by the two utilities during recent years. It is a tribute to the effectiveness of this cooperative work that the degree of satisfactory coordination between the two systems is steadily improving.

In the following pages brief statements are made descriptive of the more important trends in the respective systems.

Trends in Telephone Practise

Present trends in telephone system include:

1. Dial system.
2. Extension of toll cable.
3. Increased use of telephone repeaters.
4. Carrier telephone systems.
5. Improved station apparatus.
6. Connections to foreign countries.

Extensions in the telephone toll system and improvements in the service generally, tend to increase the number of coordination problems and their importance. Extended use of toll cable tends to reduce these same problems, since cable is less susceptive than open wire and its use allows many more circuits to be carried over a single route, thereby reducing the number of routes.

Probably the most fundamental and far reaching of these changes is the progress of conversion from manual to dial system operation. When present plans are completed approximately 80 per cent of the telephones of the Bell System will operate on a dial basis. While this trend is of the greatest and most fundamental importance in the development of the telephone business it does not affect the coordination problem in any material way and therefore need not be further discussed here.

One of the most spectacular trends of development of the Bell System at the present time is the increase in the connections to foreign countries. Earlier connections to Canada and Cuba were supplemented in 1927 by service to Mexico and by transoceanic radio links from New York to London through which connection is made to the principal European countries; and in 1930 a similar radio link from New York to Buenos Aires through which connection is made to Montevideo, Uruguay, and Santiago, Chile. During the next few years it is expected that these foreign connections will increase to include all important points in South America, Australia, Japan, Honolulu, and all other points which may offer an appreciable demand for service. These intercontinental circuits are not directly affected by the physical proximity of power circuits; but their efficiency is affected by noise currents on connected circuits.

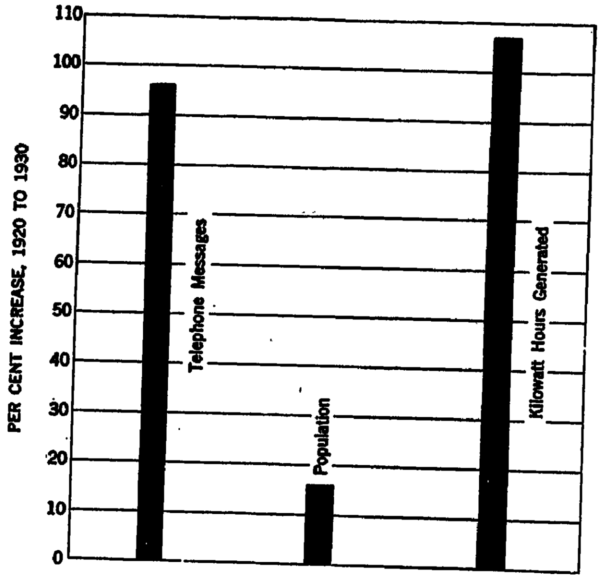

Fig. 1. Growth in the utilization of power and telephone service as compared to growth in population for the period 1920-1930, expressed in percentage of increase

Toll Cable Increasing

The change in methods of designing and constructing toll circuits which is of greatest importance is the great increase in use of cables for such circuits, including both the very long distance circuits and the shorter interurban circuits. A single cable may provide from 250 to 500 telephone circuits and several hundred telegraph circuits, as many circuits as would be supplied by from five to ten heavily loaded open-wire pole lines.

This concentration of circuits in a single cable, a number of which can be placed on a single route, of itself greatly simplifies coordination problems by materially reducing the number of routes involved.

Furthermore, the presence of the lead sheath with the twisting of the cable conductors, the high degree of balance with respect to ground, and the mutual shielding effect of the many circuits in one cable, practically prevent the direct induction of noise currents into the cable circuits from outside electrical sources. The shielding effect of the lead sheath when suitably grounded also provides substantial reductions in the voltages of fundamental frequency which may be induced along the cable conductors at time of trouble on neighboring power systems.

A telephone toll cable with its associated equipment costs about the same per mile as a twin-circuit power transmission line of the 110-kv. class. This high cost has led to a large use of private rights-of-way for new extensions of these cables, particularly for aerial cable construction—an added advantage from the coordination standpoint.

In all types of cable construction the susceptiveness to noise induction is so greatly reduced that low frequency induction generally becomes the limiting factor relative to the permissible proximity of these cables to power circuits. The relative amounts of induced voltages occurring with certain types of cable construction as compared with open-wire construction are in the order of 1:5.

While as noted cable circuits are protected effectively from noise induction, the efficiency obtainable over the long circuits is limited in part by the noise currents occurring in the open-wire lines which may be switched to the long cable circuits. This is because the efficiency of the long cable circuits depends upon voice-operated switching devices which must not be operated by the noise currents. This is true also of the intercontinental circuits. Extension of the circuits controlled by voice-operated devices therefore tends to increase the importance of good coordination of the entire plant.

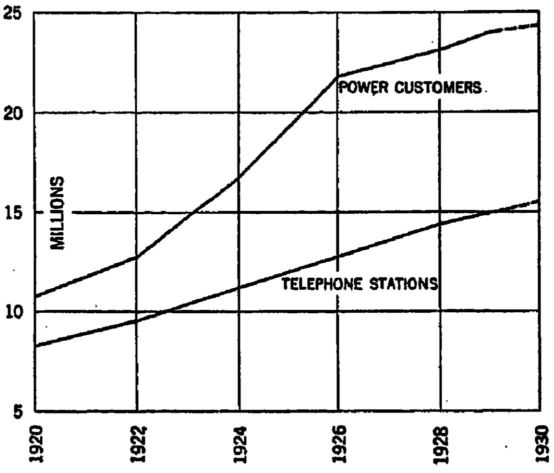

Fig. 2. Growth in the number of telephone subscriber stations and electric power customers for the decade 1920-1930

Repeaters and Carrier Systems

Another important trend of practise is the wide use of telephone repeaters, the purpose of which is to amplify the voice currents and thus make possible higher efficiency and greater extension of long distance telephone circuits. Without repeaters it was necessary on the long open-wire circuits to permit the power level of voice currents to sink to relatively low values. An extreme example of this is given by the New York-Denver circuit which, before repeaters were available for use, had an over-all ratio of output power to input power of 8:10,000. With the application of repeaters, the level of voice currents can be kept relatively high throughout the circuit.

The use of repeaters thus contributes to reducing the susceptiveness of the telephone plant and aids coordination. On a circuit such as the original New York-Denver circuit a relatively small amount of noise current greatly impaired transmission because of the weak incoming voice currents.

A third important trend in telephone practise is the extension in the use of carrier telephone systems for long circuits and the associated changes in aerial wire construction practises. The carrier systems are much less influenced by noise induction from power circuits because they occupy a range of frequencies (5,000 to 30,000 cycles) in which the harmonic power voltages or currents ordinarily are extremely small.

Subscribers' Station Apparatus

To a great extent the trend of development in subscribers' station apparatus is toward new arrangements which provide fuller convenience and more closely meet the needs of the users, and which have no material effect upon the coordination problem. An important group of developments, however, centers about the improvements in electrical performance of station apparatus accomplished by removing impairments caused by the earlier types of apparatus. These changes, by improving the quality of speech as reproduced by the telephone system, tend to make more noticeable the impairments caused by the effects of currents induced from external sources.

The tendency toward an increase in the range of voice frequencies efficiently reproduced by the telephone system tends to increase also the range of induced currents which may cause noise interference. An extreme illustration of this is represented by the circuits designed to transmit programs for radio broadcasting stations. Transmission characteristics of these circuits have been improved to accommodate efficient transmission of currents of frequencies ranging from 35 to 8,000 cycles per second. Thus these circuits are susceptible to inductive noises over this same wide range.

Room noise at subscribers' premises, besides acting directly on the ears of the telephone user, is converted by the transmitter into electrical currents which in turn produce receiver noise. Efforts now being made to reduce these effects inevitably will tend to bring into increasing prominence noises caused by induction which now in many cases are partially overshadowed by reproduction of room noises.

To offset this tendency, at least partly, steps have been taken to improve the degree of balance-to-ground of new station apparatus, particularly in the case of party lines.

OTHER ITEMS

Other features not directly associated with these trends, and introduced into the telephone plant largely because of the advantages to be gained in reducing susceptiveness to electrical influences, have afforded other benefits also. Interesting examples of these changes include recent adoption of soldered joints to replace twisted sleeve joints and the substitution of copper for iron wire on short tributary toll circuits. In toll offices improvements have been made in the balance of coils and condensers used for superposing telegraph on the telephone circuits. The use of repeating coils, commonly used for side-circuits, has been extended to phantom toll circuits. These coils act as insulating transformers to prevent noise voltages from the outside conductors being impressed upon the intricate cabling and equipment of the office.

Referring to the local plant, there are several noteworthy examples of modifications made principally for the purpose of reducing susceptiveness. Coordination investigations such as were conducted at Minneapolis by the joint general committee have stimulated the development of means for reducing the susceptiveness of the telephone distribution plant.

With the rapid increase of voltage and capacity of power circuits generally, experimental studies have been undertaken to ascertain further means of maintaining the safety of persons working or listening on telephone circuits. At the present time, development work is under way on various devices for this purpose, some of which are fundamentally different in design and operation from those previously used. It is hoped that these devices will afford increased protection against over voltages and improve coordination and conditions.

TRENDS IN POWER PRACTISE

Current trends in power system development include:

1. Interconnection of large systems.
2. Higher transmission and distribution voltages.
3. Larger generating units.
4. Improved system stability.
5. Control of the effects of lightning.
6. Underground construction.
7. Improved wave shape.
8. Increasing use of automatic devices.
9. Better frequency regulation.
10. Better voltage regulation.

The first three items are likely to increase the number of coordination problems and make certain of them more difficult; distinct help in reducing the coordination problem is afforded by Items 4-7 inclusive; the last three may be said to be beneficial but of less importance.

Those trends in power system development which are more directly concerned with matters of coordination are discussed in the following paragraphs.

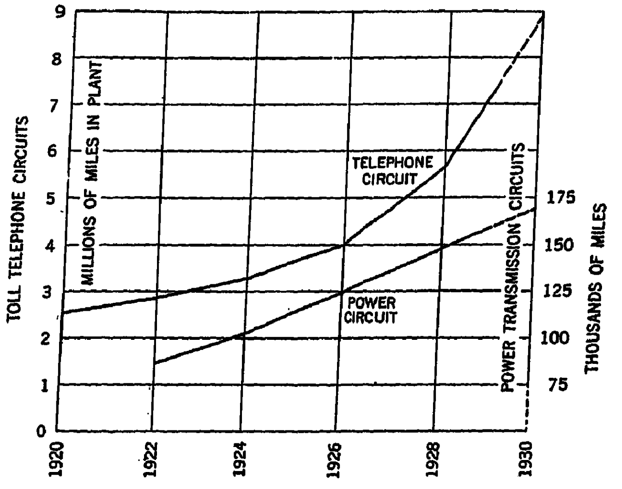

Fig. 3. Record of a ten years' growth in mileage of long distance telephone toll circuits and electric power transmission circuits of 11 kv. and higher. Telephone circuit mileage is given in millions; power circuit mileage in thousands

SYSTEM VOLTAGES

Statistics show that the rate of increase of transmission line mileage, as a whole, is lagging behind the rate of growth of both installed generator capacity and electricity production. Furthermore, mileages of the higher transmission voltages (220 kv., 132 kv., 110 kv., and particularly 66 kv.) are growing at a more rapid rate than the group average. These comparisons reflect the increasing utilization of the higher voltages with the greater circuit capacities they provide.

In the distribution field also, coincident with the development of rural service, there is a movement toward higher voltages in primary circuits. Voltages from 6.6 kv. to 13.2 kv. and higher have been used in rural work. In urban areas the high load densities encountered have brought about replacement of the lower by higher primary voltages. In addition to the greater capacities provided by the higher voltages, possibilities of system simplification by combining rural and urban systems to eliminate voltage transformations are of considerable economic importance.

While at first glance the pronounced trend to higher transmission and primary distribution voltages may appear to enhance the difficulties of coordinating communication and power lines, certain offsetting factors enter. As transmission voltages increase there is a definite trend toward direct cross-country private rights-of-way which automatically provide greater separation from communication circuits.

In the case of distribution lines, too, the adoption of increasingly higher voltages is accompanied by more systematic grades of construction and greater clearances from communication circuits. The result of course is that fewer abnormal conditions of operation occur and the number of related disturbances in the communication circuits is reduced correspondingly.

SYSTEM STABILITY

During recent years considerable attention has been paid to the development of methods for improving system electrical stability. One of the most important of these methods is the use of higher speeds of switching,—at present, faults can be cleared in 15 cycles, or less, of a 60-cycle wave. So far, high-speed switching has been applied mainly to transmission circuits. However, as development proceeds and cost of equipment required is reduced, the field of application of high-speed switching may be extended to distribution systems. The result in the case of either transmission or distribution will be of course to reduce the duration of transients.

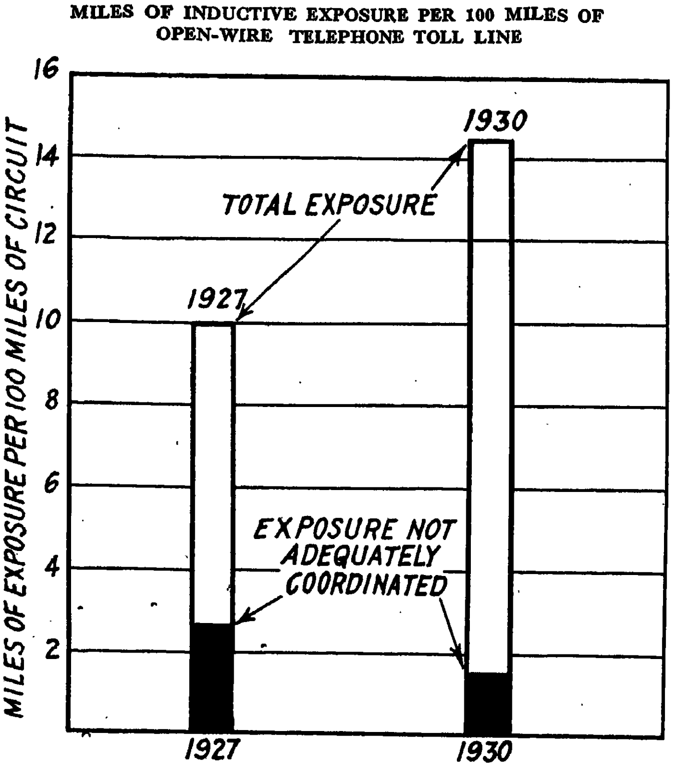

Fig. 4. Concrete evidence of the beneficial effect of the methods developed through the joint efforts of the power and telephone industries

Akin to high-speed switching, the use of high-speed excitation of rotating equipment has been developed. This may tend to increase the maximum fault-current values somewhat, which would make coordination more difficult. However, the reduction in severity of instability surges, in so far as such surges involve faults to ground, affords definite benefits from the coordination standpoint. Further study and observations are required to determine what, if any, inherent limitations or advantages high-speed switching may possess with respect to coordination work.

With the growth in power systems and major interconnections, the use of bus or feeder current-limiting reactors or other means of limiting the concentration of fault-current flow is being given increasing application. Such practise acts to restrict the magnitude of inductive transients. In distribution systems the growing use of feeder reactors has a similar effect upon coordination.

It is predominant practise in America to ground the neutrals of transmission systems at important transforming centers, sometimes through resistors or reactors, but usually solidly; thus, a large proportion of the transformers of higher voltages now in service have insulation between the neutral ends of the grounded windings and the core designed to withstand only the neutral potentials produced by fault currents regulating through the unavoidable impedance of grounding connections. Economies resulting from this method of construction become greater as rated operating voltages rise. However, the use of solidly grounded neutrals tends to make coordination more difficult in view of the possibilities for increased flow of earth currents. Increasing study and consideration are being given to the use of current-limiting devices in the neutral where the characteristics of the apparatus and limitations of relaying will permit such operation. The increasing use of neutral impedances and other types of current-limiting devices aids coordination through reduction in the magnitude of abnormal induction.

LIGHTNING CONTROL

The major problem of the transmission art at the present time is the control of lightning in its effects on service. In those sections of the country in which lightning is prevalent, this natural hazard accounts for a large proportion of transmission circuit faults, approaching 100 per cent for the higher classes of trunk transmission lines. Present measures directed toward the control of service interruptions caused by lightning include improved application of overhead ground wires, improved grounding connections at the supporting structures, greater use of wood for lightning insulation, the use in shunt with line insulators of fused gaps, or other valve devices to "spill" the surge without dynamic current follow-up. There is under consideration also the application on grounded-neutral systems of single-phase switching. All of these measures, with the exception of the last, are helpful from the coordination point of view since their effect is to avoid or reduce system faults or at least to decrease the magnitude of earth fault currents and hence, of the accompanying voltages induced in nearby communication circuits.

UNDERGROUND CONSTRUCTION

Underground construction in distribution systems seldom is economical; but it is increasing in high-load-density districts and in some residential areas primarily in response to requirements for civic improvements and the relieving of surface congestion. Coincident with the more recent developments in underground distribution, certain special situations have brought about the development of underground cable suitable for use in high-voltage transmission circuits, including 132-kv. Underground installations involving these transmission voltages are comparatively few in number and small in extent. Underground construction of both distribution and transmission circuits has a definitely favorable effect upon coordination problems.

Aerial cable construction for both distribution and transmission circuits has been used to a limited extent and has a definitely beneficial effect upon coordination matters. Whether this type of construction will be extended in the future is not evident.

GROUNDING OF DISTRIBUTION SYSTEM NEUTRALS

Because of the difficulties encountered in distribution systems in obtaining adequate grounding of primary and secondary circuits, the establishment of neutral networks grounded at many points has become a practise. In most past cases separate primary and secondary networks have been provided, but recently in several localities, the two have been combined into a common-neutral arrangement providing increased multiplicity of ground connections. Wider use of the system is probable.

This common-neutral arrangement introduces features of interest from the coordination standpoint, because of the increased opportunities for the flow of currents through the ground. Experience and investigations so far, however, indicate that with adequate attention to coordination, this arrangement is comparable in its effect on neighboring communication circuits to other types of distribution systems.

WAVE SHAPE

Connection of primary circuits directly to generating station buses results in service and economic advantages through elimination of transformations, thereby improving voltage regulation and aiding system simplification. This practise, however, tends to make coordination more difficult because harmonics which may be present in the generated voltage can flow directly out over such circuits. However, the important bearing of generator and apparatus wave shape upon the coordination problem long has been realized and is receiving increasing attention.

It is recognized that there is a median beyond which, (to avoid the alternative of applying in specific cases available and less expensive methods of externally correcting wave shape,) general improvement in the inherent wave shape of apparatus would not justify the attendant increased difficulties of design and increased manufacturing costs. Looking toward establishing a measure of wave shape in apparatus design which will strike an economic balance between benefits and burdens, work is now in progress cooperatively between the manufacturers and the users.

Increasing use of rectifiers for conversion from alternating to direct current also has an influence on inductive coordination. Study devoted to this matter has revealed methods for control of the distortion of the d-c. voltage wave caused by the rectifiers, and a solution of this part of the problem appears to be in hand. Progress in the design and application of apparatus, and the better understanding of the influence of circuit and transformer connections on inductive relations, indicate that problems concerned with wave shape may be expected to decrease steadily.

CONCLUSIONS

In reviewing this subject one is impressed by the number of ways in which the coordination problem touches both the telephone and power fields, and with the very large amount of cooperative work which already has been done. This work, as has been indicated, has resulted in noteworthy progress in the satisfactory handling of coordination matters of all characters. The situation concerns two industries which are in a period of rapid development and change, both as regards their size and as regards the physical arrangements which constitute their plants. Many new developments in each plant require consideration from the standpoint of coordination.

It is evident, therefore, that if the ground already gained is to be held, and further progress made, the channels of cooperation between the two industries must be kept in operation for the consideration of new problems arising with new developments in the industries, as well as for the further perfection of the cooperative methods of handling existing specific problems.

Light Beams Operate Traffic Signals

Efforts to perfect automatic devices which will give major highways a green light at all times except as change is actually required by traffic on minor intersecting streets now have turned to the grid-glow and photoelectric tubes. Operating experiences gained from trial installations are discussed and equipment features are outlined.

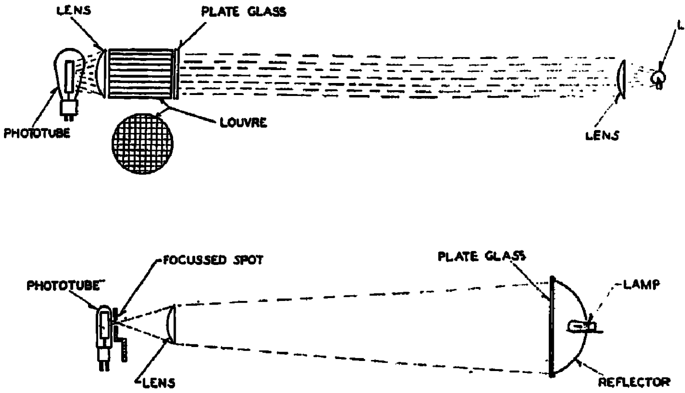

Fig. 1. Optical systems showing light-beam transmitting and receiving apparatus: (above) second installation; (below) third, improved installation

By R. C. Hitchcock

Westinghouse Electric & Manufacturing Company
East Pittsburgh, Pa.

TRAFFIC CONTROL at intersections of streets carrying light traffic with streets or boulevards carrying through-city or cross-country traffic presents one of the most perplexing problems with which police departments and other traffic controlling bodies have to deal. The problem is complicated still further when it is considered that the ratio of major traffic to minor traffic may vary as much as from 3:1 to as high as 50:1, or even higher on some occasions, at the same intersection.

Devices employing photoelectric and grid-glow tubes actuated by light beams provide automatic adjustment of signal operation to traffic requirements by maintaining a green or "go" signal on the major traffic street at all times when there is no traffic on a minor intersecting street.

Devices actuated by traffic on both of the intersecting streets are in use in some locations, with no special signal program. Such equipment must be very carefully designed and frequently inspected, for should failure occur in any unit, signals may remain as they were at the time of failure. With the major-minor device described here, the failure of any of several units causes the vehicle-controlled light-beam device to be disconnected automatically, and the regular timer motor which is incorporated into the apparatus, to then control the traffic at the intersection on a predetermined cycle.

As an example showing how, this system may be applied to a typical major-minor intersection, assume a one-minute traffic cycle with a timing of: 42 sec. major street green, 3 sec. amber, 12 sec. minor street green, and 3 sec. amber. Thus the ratio of green light for major and minor streets is 42:12 or 3.5:1; yet this timing is frequently used at an intersection where the traffic ratio ranges from 10:1 to 50:1, and where 1,000 or more cars per hour are passing on the major street. The reason for the short major cycle is to allow the minor street vehicles to enter the intersection after a maximum waiting time of 45 sec. All this is done with the new automatic controller; at the same time the major street is allowed as much more than a 42-sec. green-signal period as the minor traffic permits.* In addition, after the first 45 sec. of major street green, the minor traffic wait is only about 5 sec., or just long enough for the automatic device to function.

EARLY EXPERIMENTAL INSTALLATIONS

During the early development work on this apparatus, in order to study the performance of the devices under actual operating conditions two trial installations were made at minor intersections.

Fig. 2. Location of control units at intersection of minor street with William Penn—Lincoln Highway, Wilkinsburg, Pa.

---

* From "Traffic Control by Light Beams," (No. 31-34), presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

In the first installation vertical light beams were used; but so much difficulty was experienced with grease and dirt falling on parts of the apparatus mounted below the street surface that this installation soon was discontinued. In subsequent installations a horizontal light beam has been used, placed at such a height that it can be operated by any type of vehicle now on the market. The optical system used in the second installation is shown in Fig. 1; as may be noted, a lens system focussed an image of the lamp filament on the photoelectric cell through a louver. This louver consisted of a square, sectional honeycomb which passed light parallel to its axis but prevented the passage of light entering at an angle of even a few degrees.

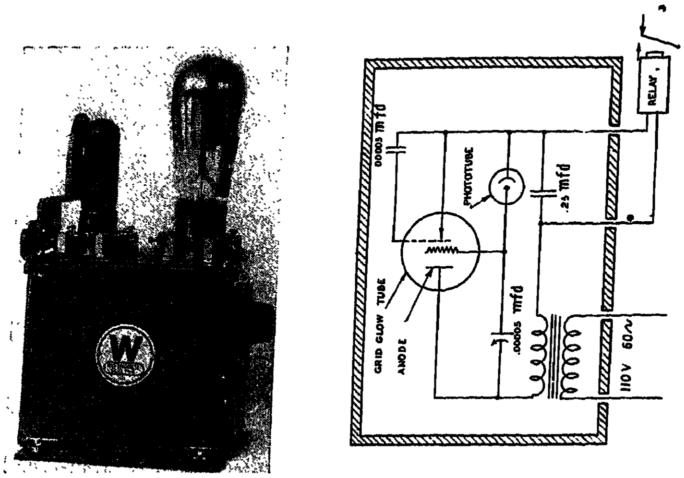

Fig. 4. Grid-glow phototube unit showing schematic wiring diagram and complete assembly of device

One interesting problem encountered during early experiments was the operation of the signals by cars making turns from the major into the minor streets. Thus a green light would be given to the minor street with no traffic waiting for it. This problem was solved by introducing a time-delay relay into the light beam operating circuit. This relay was timed so as to require an approaching vehicle to intercept the light beam for several seconds before a change of signal lights took place. In this way no change of signal lights such as those caused by vehicles making turns resulted from momentary interruptions to the light beam.

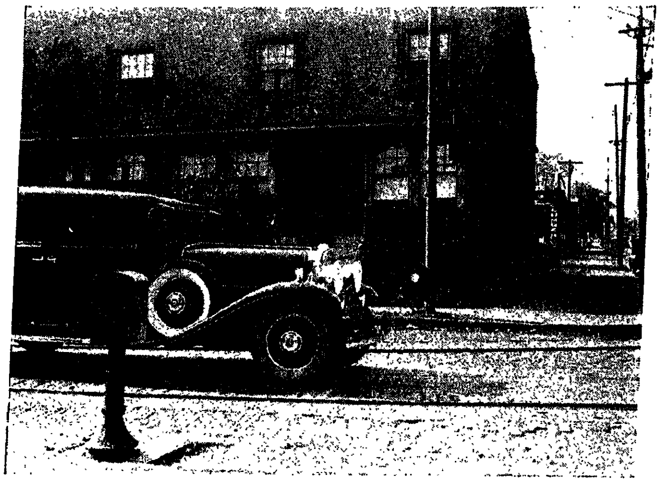

Fig. 3. Vehicle intercepting horizontal light beam

Unusual reliability for a device still in the development stage was demonstrated by this second installation. After five months' operation only three interruptions have occurred—two of these due to dirty lenses and resulting from the apparatus going on "program" operation; and the third due to a loose connection which resulted in one relay box being out of service for about two hours. Also during this period, one of the lamps in this installation for 4⅓ months burned out and after 4½ months one of the original glow tubes was replaced.

THIRD INSTALLATION

With certain changes as dictated by operating experiences with the second installation, a third set of apparatus was built and installed in Wilkinsburg, Pa., at the intersection of a minor street with the street which carries traffic from both the William Penn and Lincoln highways through the town. This installation was completed on September 16, 1930. Location of the control boxes at this intersection is shown in

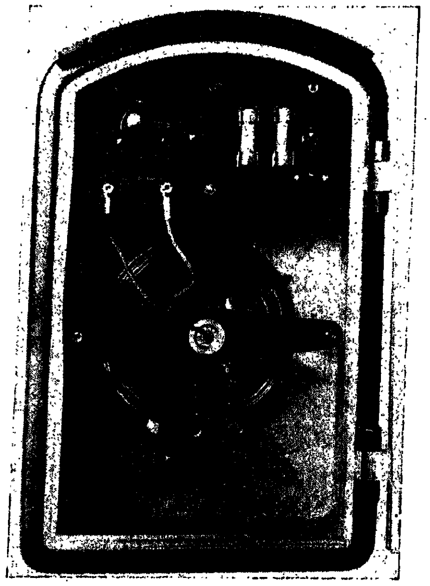

Fig. 5. Rear of reflector unit showing lamp mounting, rheostat, and switch

Fig. 2. A vehicle intercepting the light beam in one set of these units is shown in Fig. 3.

Fig. 4 shows the grid-glow phototube unit used in the third installation. Paraffin-impregnated cork washers together with a special clamping device were found to keep the tube bases free from moisture and dirt. Both the transformer and condensers with their associated wiring are contained inside of a small casting, as shown. The upper panel is made of moldarta and is screwed to the casting with a paraffin-cork gasket to keep it moisture-tight. The no-load loss of the transformer provides sufficient heat to prevent condensation of moisture within this casting. In this connection, tests were made with the grid-glow phototube unit in a humidifier. With the humidity at 100 per cent, water was sprayed over the unit several times. Under these extreme conditions the paraffin-cork washers and gaskets held their seal and the unit operated satisfacfactorily for several hours.

The complete optical system of the third installation is shown in Fig. 1. With the exception of the front the glass of the phototube is painted black. This keeps daylight out of the tube so that with the back of the control box open adjustments may readily be made. As may be noted in both Figs. 1 and 4, a shield containing a small hole on which the light source is focussed, is placed in front of the phototube, thereby keeping out extraneous light.

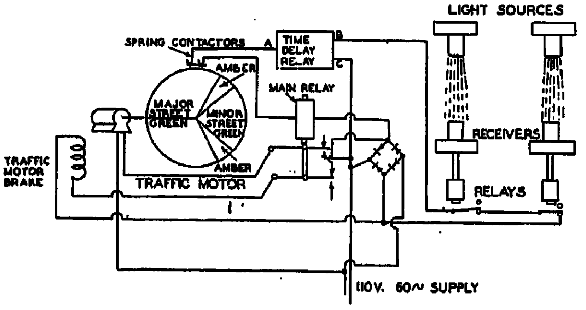

Fig. 6. Schematic diagram of latest installation

Experimental results indicate that a fairly good parabolic reflector such as used in this third installation is better than any reasonable-priced lens of similar diameter as used in the second installation. As a result of this improved optical system, lower lamp filament currents may be employed; this in turn means longer life for lamps. A rear view showing the reflector of the lamp-unit box may be seen in Fig. 5. The lamp socket has two knurled clamp nuts which allow motion of the socket in and out, while a large hole in the support permits lateral motion. A resistor is provided in series with the primary of the lamp transformer so that its voltage may be varied to suit.

Schematic wiring diagram for the third controller is given in Fig. 6. As shown in this diagram the major street signal is green, the main relay is pulled up, power is off the motor, and the brake is on. When a car crosses the light beam momentarily as in turning from the major into the minor street, the light-controlled relays pull up, and the circuit wires *A* and *B* of the time-delay relay are open-circuited. However, unless the car remains in the beam for the specified time delay there is no further action in the controller. But if a car does wait in the beam for the specified time, circuit *A-B* remains open, the traffic motor starts up, and the cycle begins, giving amber and then green to the minor street.

Arrangement of parts in the main control unit is shown in Fig. 7. This view shows the rear of the box at the top of which may be seen some of the time-delay apparatus. Of particular interest is the method of mounting the grid-glow-phototube unit which can be seen at the bottom of the box.

Fig. 7. Rear of main-control box containing grid-glow phototube unit and time-delay apparatus

It is interesting to note that at the time of writing this third installation has been in operation for about one month and no service interruptions have occurred. By actual timing, the major street has been found to receive a green signal for periods as long as five minutes at times of extremely light traffic on the minor street.

Operations described in the foregoing paragraphs have been accomplished purely experimentally; the equipment is not available for commercial usages.

CONCLUSIONS

In summing up the results so far obtained with these devices it may be said that:

1. The red light was flashed on the major street from 50 to 70 per cent less than when using the regular cycle timer.
2. Glass parts of the apparatus should be cleaned about once a month, at which time a routine inspection should be made.
3. Reliability of operation is assured by the traffic-timing mechanism incorporated into the apparatus.
4. Increased reliability with less frequent inspection will result with the use of the longer-life tubes now being made.

Lackawanna Electrification Improves Suburban Service

Establishing a noteworthy precedent in the railroad world the Delaware Lackawanna and Western Railroad's recently completed suburban electrification places entire dependence upon 3,000-volt mercury arc rectifiers. Other features of design include the use of trolley voltage directly across car heaters, and general planning of all designs and equipment selections to permit extension of electrification throughout the system to serve overland freight and passenger trains.

By Edward L. Moreland
Fellow A. I. E. E.
Jackson & Moreland, Consulting Engineers, Boston

ELECTRIFICATION is enabling many steam railroads to solve problems of handling increasing amounts of suburban passenger traffic, where the bulk of such traffic comes in comparatively short morning and evening periods. The Delaware, Lackawanna and Western Railroad faced just such a problem in connection with its suburban lines in New Jersey when increasing demands made on these lines by New York traffic necessitated faster, cleaner, and more frequent train service. This was possible only through electrification.

In pursuing the present electrification program all designs and equipment selections were influenced by the ultimate possibility of complete electrification of the entire Lackawanna system, which includes both overland passenger and heavy freight service. A novel feature of the development is the use of 3,000-volt mercury arc rectifiers throughout for train supply. These devices have been proved to be lower in first cost and higher in operating efficiency at all loads than any other type of converting apparatus.

The present electrification covers approximately 68 route miles and 158 track miles of line in the suburban district west of Hoboken, N. J., and includes the main passenger line from Hoboken to Dover (via Newark, the Oranges, Summit and Morristown) and the branch lines to Montclair and Gladstone. It covers only local passenger service except for the electric transfer of freight trains between the freight classification yard at Secaucus and the terminal pier-head yard in Jersey City, adjoining the Hoboken terminal. In the passenger service multiple-unit cars are used exclusively, while for freight transfer service "three-power" locomotives are employed.

POWER SUPPLY AND SUBSTATIONS

Power for the electrification is purchased from the three power companies serving the territories in which the substations are located, and is delivered by the power companies to the five railroad substations in the form of three-phase, 60-cycle alternating current, at the voltages available on the power companies' systems in the vicinity. There is no transmission of a-c. power by the railroad along the rights-of-way used for traction purposes.

The locations of the substations are shown on the map (Fig. 1). Power is supplied at the West End and Roseville substations by the Public Service Electric and Gas Company at 13.2 kv. and 26.4 kv., respectively; at the Summit substation by the Jersey Central Power and Light Company at 66 kv.; and at the Bernardsville and Denville substations by the New Jersey Power

---

From "Lackawanna Suburban Electrification," (No. 31-18) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

and Light Company at 33 kv. The West End and Roseville substations are supplied by underground cable circuits and each of the other three substations by overhead lines.

Four of the substations—namely, West End, Roseville, Summit and Denville—are at junction points and an operator will be kept in attendance at all times. They, therefore, are not equipped with complete automatic control, although many of the functions are automatic. The Bernardsville substation is fully automatic with supervisory control from the Summit substation 13.4 mi. away.

Mercury arc rectifiers are used exclusively for converting from 60-cycle alternating current to the 3,000-volt direct current required for traction purposes.

A-C. Supply Circuits and Control. A typical substation showing the arrangement and connection of the rectifiers and associated apparatus is given in cross-section in Fig. 2. A-c. switching structures are of the outdoor type in all substations.

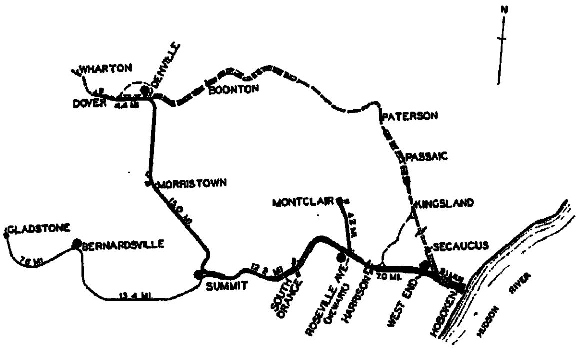

Fig. 1. Map of Lackawanna suburban lines east of Dover, N. J., showing electrified sections and substation locations

Connections from the a-c. bus to the rectifier transformers are through oil circuit breakers with instantaneous overload protection. The main transformers have three-phase delta-connected primaries, with ratio adjusters externally operated from the ground, and all twelve-phase zig-zig secondaries are provided with protection against overheating.

At the West End and Roseville substations the incoming a-c. power feeders are connected to the bus through oil circuit breakers and disconnecting switches. Both of these substations are equipped with four twelve-phase transformers each supplying power to a twelve-phase, 3,000-kw. rectifier tank.

At the Summit and Denville substations the incoming a-c. power feeders are connected to the bus through horn-gap air-break switches. In these cases the oil circuit breakers in the power companies' substations supplying the feeder circuits are relied upon to clear the associated circuit in the event of a fault on a section of the bus. If, however, conditions on the power companies" systems should change so that the present method of operation would no longer be satisfactory, provisions are made for later installation of oil circuit breakers instead of the horn-gap air-break switches. These two substations are each equipped with two twelve-phase transformers each supplying power to two six-phase, 1,500-kw. rectifier tanks. Normally, both rectifier tanks of each two-tank unit will be operated together; but in event of failure of one tank of a pair, the faulty tank can be disconnected by opening disconnecting switches provided in the leads to the anodes, and the other tank operated alone.

At the Bernardsville substation incoming a-c. power feeders are also connected to the bus through horn-gap air-break switches. Normally this station will be supplied from one circuit, the second circuit being used only in case of failure of power on the first circuit. At this substation there are two twelve-phase, 1,500-kv-a. transformers, each supplying power to a twelve-phase rectifier tank.

In all stations, lightning protection to the a-c, bus is provided by oxide film-type lightning arresters.

D-C. Bus Arrangement and Circuit Control. On the d-c. side of each substation, main and auxiliary buses are provided, each bus being sectionalized by a disconnecting switch, but operated normally with the secionalizing switch closed. The d-c. feeders connecting the substation bus to the catenary system are controlled by high-speed circuit breakers of the magnetic blow-out type, with holding coils energized from a storage battery.

In all stations, a lightning arrester of the electrolytic aluminum cell type, with balancing resistor and shunted spark-gap, is provided on each d-c. feeder and on the d-c. main bus.

Bernardsville Automatic Substation. As previously mentioned, four of the five substations are manually operated. The fifth, Bernardsville, is fully automatic with supervisory control from the Summit substation. Normally power will be supplied to this substation over a single circuit, but provision is made for automatically throwing over to a second circuit in the event of failure of power on the first. Once having changed over to the second circuit, the system does not automatically change back to the first circuit on restoration of power on that circuit unless there is a failure of power on the second circuit.

The automatic features provide also that either of the two rectifier units may be made the preferred unit, and that the second unit will come automatically into service when the load on the first exceeds a predetermined amount; this second will then drop out automatically after a predetermined time delay when the total substation load drops below a certain amount. The preferred rectifier may be kept on the line continuously or the control may be further adjusted to bring it on only when there is a load demand on the substation, and to take it off the line after a definite time delay when the load has decreased below a predetermined amount. In the event of a fault on either rectifier or any of its auxiliary circuits, that rectifier is automatically locked off the line. If the fault is on the preferred rectifier, the second rectifier will take its place automatically.

Signal and Auxiliary Power Supply. In addition to the 3,000-volt direct current supplied from the substations for traction purposes, each of the substations furnishes 2,300-volt, single-phase, 60-cycle power for signal operation. The West End, Roseville and Denville substations also supply 6,600-volt, three-phase, 60-cycle power for railroad auxiliaries, station lighting, and miscellaneous power requirements along the right of way.

Rectifiers. Rectifiers rather than motor-generators were selected for the conversion of the 60-cycle a-c. power to 3,000-volt d-c. power because of their relatively low first cost, high efficiency, ability to carry heavy overloads without injury, and the economy of substation design resulting from the small space occupied and the absence of heavy foundations required for motor-generators. Fig. 3 shows the comparative efficiencies of 3000-volt mercury arc rectifier sets and motor-generator sets of similar capacities.

These rectifiers were bought under a specification requiring guarantee of successful operation in service under loads of 150 per cent of current rating (50 per cent overload) for two hours and 300 per cent of current rating (200 per cent overload) for five minutes.

The rectifier tanks are equipped with the usual arc-striking anodes, holding (or exciting) anodes, vacuum pumps, and gages. The tanks are water-cooled, using a closed cooling system with forced circulation under thermostat control. The circulating water for each rectifier tank is re-cooled in a cooler unit associated with that tank somewhat similar to an enlarged automobile radiator using a circulating pump and motor-driven fan. Heating elements under thermostat control are also provided to prevent various parts of the rectifiers becoming too cool when shut down or lightly loaded.

D-c. smoothing reactors to reduce the ripple in the d-c. voltage, and resonant shunts to drain off high-frequency harmonics which would cause interference on communication circuits, are also provided. Surge suppressors made up of capacitors with limiting resistors are provided to protect the transformer secondary windings and the interphase transformer windings against high-voltage surges.

The shell of the rectifier tank and some of the associated equipment is at substantially cathode potential (3,000 volts above ground) when the rectifier is in operation. This equipment is therefore insulated from ground and carefully protected from accidental contact while in operation.

Fig. 4 is an interior view of a substation, showing the arrangement of the rectifiers and enclosing grilles.

In addition to the overload protection provided by the oil circuit breaker on the a-c. side of the transformer, each rectifier unit is protected by a high-speed circuit breaker of the magnetic blow-out type on the positive side (cathode connection) and by a similar high-speed circuit breaker short-circuiting a load-limiting resistor on the negative side (connection to mid-point of the interphase transformer).

Rectifier Grid Excitation. Aside from the voltage and capacity of the units, the outstanding features of the Lackawanna rectifiers are the anode grid excitation and the automatic compounding. In addition to the usual provisions for shielding the anode from the mercury thrown up from the cathode mercury pool by the arc stream, each anode is also surrounded by an inner shield suspended from a porcelain insulator. This shield supports a mesh grid made of special high-melting-point metal and mounted just below the face of the anode; it is insulated both from the anode and the tank case. Voltage applied to the grid ionizes the mercury vapor near the face of the anode and thus assists in establishing the power arc.

Rectifier Compounding. The rectifier compounding circuit is shown diagrammatically in Fig. 5. The main power circuits are indicated by the heavy lines and the auxiliary compounding circuits by the lighter lines. As shown on the diagram the twelve-phase

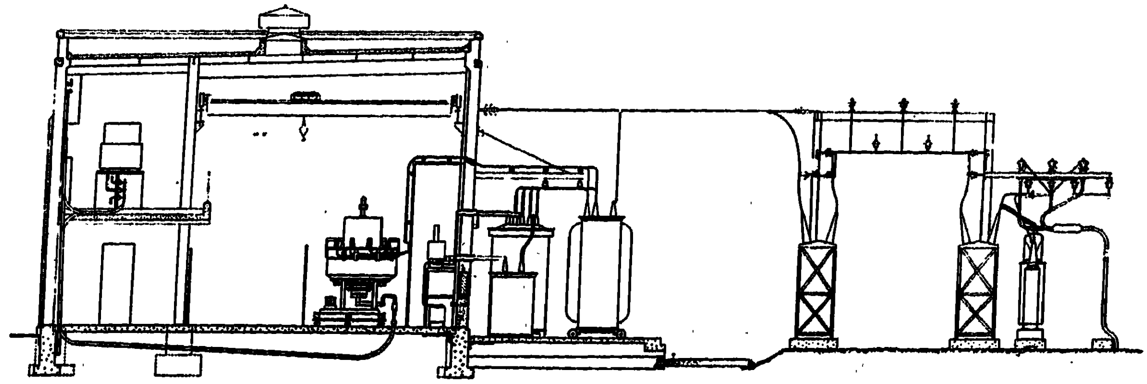

Fig. 2. Transverse sectional elevation of a typical Lackawanna substation showing equipment arrangement

secondary of the main transformer is made up of four three-phase secondaries with their neutrals connected together through interphase transformers.

The compounding is accomplished by shunting the third-harmonic interphase transformers (which connect neutral N^1 with N^2 and N^3 with N^4) by means of two tuned compounding circuits, each containing a capacitor and one winding of a compounding reactor. At very light loads the d-c. voltage corresponds substantially to the voltage of a three-phase rectifier; as load comes on, due to the shunting of the third-harmonic current from the interphase transformer winding through the compounding circuit, the condition approaches more and more nearly that of the six-phase rectifier, which gives approximately 15 per cent higher d-c. voltage with the same a-c. secondary coil voltage. The characteristic curve of one of the Lackawanna rectifiers when running compounded as determined by test, is shown in (a) of Fig. 6. For comparison the characteristic (b) when running non-compounded is also shown.

The power factor of the compounded rectifier unit including the transformer is notably high, showing approximately 96½ per cent lagging at 25 per cent load and increasing with load to 99 per cent lagging at 50 per cent load; at 150 per cent load it leads slightly but drops back to 99 per cent lagging at 300 per cent load. Due to the fact that they are connected in circuits carrying third-harmonic frequency the effect of the compounding capacitors on the power factor is greatly increased.

When compounded rectifiers are run in parallel it is necessary to provide an equalizer bus connected above the compounding reactor as indicated in Figs. 2 and 5, in order to assure equal compounding effect and equal division of the load between parallel units.

MULTIPLE-UNIT CAR EQUIPMENT

The multiple-unit car equipment in the initial electrification consists of 141 two-car units, each unit consisting of one motor car and one trailer car semi-permanently coupled together, with a control position and motorman's cab at each end of each two-car unit.

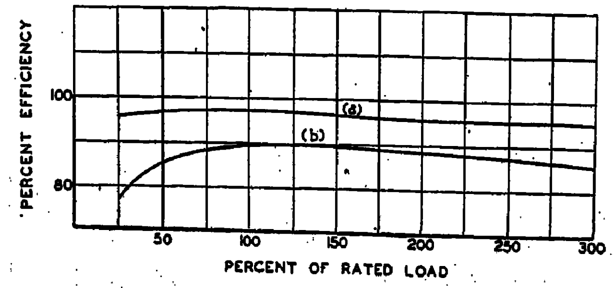

Fig. 3. Comparative efficiencies (including transformers) of (a) D. L. & W. 3,000-volt, 3,000-kw. mercury arc rectifiers and (b) 3,000-kw. motor-generators considered for use in the electrification

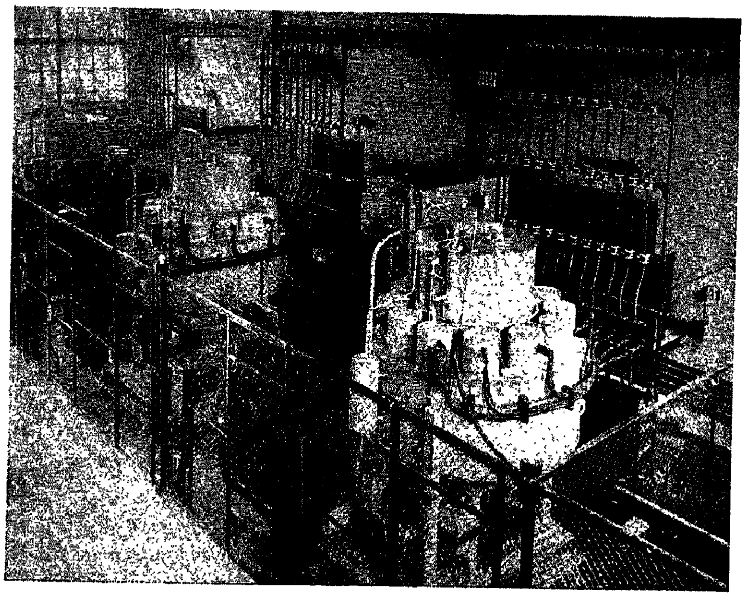

Fig. 4. Typical rectifier installation

Trains of from two to twelve cars are made up by coupling units together, the train control circuits connecting from unit to unit (and from car to car within the unit) by means of jumpers with plug connectors.

All motor cars are new steel cars, 70 ft. 3¼ in. long over bumpers, seating 84 passengers, and weigh, completely equipped, approximately 147,000 lb. without passengers. All trailer cars are remodeled steel cars formerly used in steam service. They seat 78 or 82 passengers, depending upon the type (except combination baggage and passenger cars and club cars, which seat less), are approximately 70 ft. long, over bumpers, and fully equipped weigh from 105,000 to 110,000 lb., exclusive of passenger load. Fig. 7 shows a view of an eight-car train made up of four of the two-car units. An extra express car (not electrified) is hauled on certain trains during non-rush hours.

Motor Equipment. Each motor car is equipped with four motors of 235 hp. (one-hour rating) each, the capacity of the motors being fixed by the requirements of local service with frequent accelerations. The motors are operated with series-parallel connections starting with four motors in series and cutting over to two parallel groups of two in series as the train comes up to speed. All motors, however, are insulated for the full 3,000 volts.

The motors are self-ventilated, using a series pull-push system. The cooling air is taken in through louvers at the top of the car, passes through settling chambers over the vestibules, then down through ducts built into the sides of the car and under the car, then through flexible "pants-leg" ducts to the motors. The air enters the motor at the commutator end through an end-housing connection admitting the air to the armature inside the commutator bell. It is sucked through the armature by the fan on the pinion end of the motor and forced back through the field windings to a discharge port at the commutator end of the housing.

Fig. 5. Simplified diagram of rectifier compounding circuit

Results indicate that this design is effective in keeping the motor free from dirt and snow without the necessity for filtering the air.

Control and Auxiliary Equipment. Each motor car is equipped with two pantographs, only one of which will normally be used at a time. The pantographs have four self-alining roller bearings, are spring-raised and air-lowered, and have a working range of from 15 ft. 6 in. to 25 ft. 3 in. above top of the rail. The standard pantograph has two contact shoes each equipped with two wearing strips with a grease groove between. For comparative purposes, however, 50 pantographs have been provided with single-contact shoes, each with two wearing strips and a grease groove.

The control system operates at 32 volts supplied by a storage battery carried on the motor car. This battery also supplies power for lighting both the motor car and its associated trailer car. A master controller is located in each end of each two-car unit. This control equipment provides for automatic train acceleration of 1.5 mi. per hr. per sec. The balancing speed of a six-car train is approximately 65 mi. per hr.

A dynamotor (with two windings in series) mounted under each motor car provides 1500-volt power for operation of a 1500-volt air compressor, and also drives by direct-shaft connection, a 4-kw. battery-charging generator for charging the control and lighting battery. The dynamotor is self-ventilating, taking its ventilating air directly from beneath the car through a centrifugal air separator.

The air compressor has a displacement of 36 cu. ft. per min., and in the event of failure of one compressor of a two-unit train, is adequate to supply the total requirements of a four-car train with an ample margin of reserve.

Push-button control switches mounted in the operator's cabs provide for controlling the pantographs, the control circuit, the heater circuit, the main-line breaker, the dynamotor, the number and gage lights, and the headlights.

Heaters. Heating on all cars is supplied by totally enclosed resistance-type heaters operated under thermostat control and connected in series on 3000-volt circuits. The wiring for these heaters is shown in Fig. 8 which is a schematic diagram of the entire car circuit. On the standard passenger cars the heaters are mounted under the seats with 40 heating elements in series. The heating elements which are themselves totally enclosed and insulated are supported on porcelain block insulators mounted in steel cases, so designed as to guard fully against the possibility of coming in contact with the heating element. The heater cases and the conduits leading to them are thoroughly grounded. The heater circuit in the trailer car is supplied from its associated motor car by a heater bus jumper on the roof of the cars. There is no 3,000-volt connection between separate units, each unit being entirely independent of the other units in the train except for the control circuits connected through by jumpers underneath the cars and for the air lines which are also connected through.

CAR CIRCUIT PROTECTION

All car circuits are protected by one main fuse of a new expulsion, compression type, mounted on the roof of the car, and connected directly to the pantographs. The motor circuit is further protected by a main line breaker consisting of four magnetic blow-out contactors in series and an overload relay. All auxiliary circuits are fed as a group through a limiting resistor of 1.5 ohms (which would limit a short-circuit current to a maximum of 2,000 amperes). Each auxiliary circuit is protected individually by an expulsion fuse, the dynamo circuit having in addition a permanent resistance of 13.5 ohms connected in series.

The main fuse has a continuous rating of 300 am-

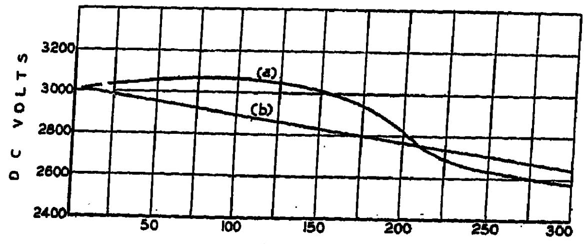

Fig. 6. Rectifier regulation characteristics showing voltage (a) compounded and (b) non-compounded

peres, or 650 amperes for 30 sec. The dynamotor circuit and heater jumper circuit to the trail car are each fused for 20 amperes, and the heater circuits for 8 amperes each.

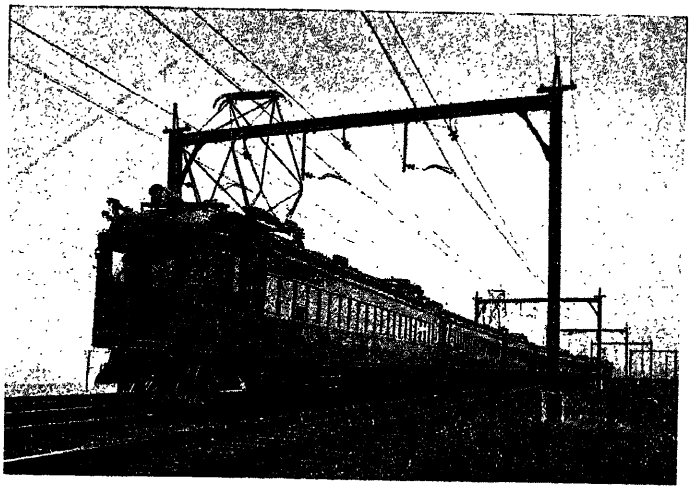

Fig. 7. Lackawanna suburban train made up of two-car units. Typical overhead construction for curved track also may be seen

Lightning protection is provided on each motor car by an electrolytic aluminum cell lightning arrester with balancing resistor and shunted spark-gap.

LOCOMOTIVES

Two locomotives of the three-power type shown in Fig. 9 have been provided for handling the freight transfer service between the Secaucus and the Jersey City yards, a distance of approximately four miles. When on electrified tracks, these locomotives operate from the 3,000-volt contact system, and when on non-electrified tracks, on internal power provided by a 300-hp. Diesel engine direct-connected to a 200-kw., 750-volt generator supplemented by a storage battery of 360 cells with a rating of 242 kw-hr. (340 ampere-hours). Each locomotive weighs 248,000 lb. with all the weight on four driving axles, is equipped with four motors of 400 hp. (one-hour rating) each and has a tractive effort of 60,000 lb. Each locomotive is capable of hauling a train of 2,500 tons, trailing load, at a balancing speed of approximately 28 mi. per hr. when operating on external power from the 3,000-volt contact system, or at approximately 12½ mi. per hr. when operating on internal power only. When running light on internal power the locomotive has a balancing speed of approximately 30 mi. per hr.

DISTRIBUTION SYSTEM

With two minor exceptions the 3000-volt power for operation of the trains is distributed through the contact system only, without the use of auxiliary positive feeders.

The catenary system is of the tangent-chord type. On main-line tracks it consists of a composite main messenger, an auxiliary messenger and two contact wires. The main messenger has a breaking strength of 31,000 lb. and an equivalent conductivity of 350,000-cm. hard-drawn copper. The auxiliary messenger is 2/0 hard-drawn copper and the contact wires are two 4/0, grooved bronze wires of 55 per cent conductivity. The total equivalent conductivity of the standard main line catenary system is 720,000-cm. hard-drawn copper per track. On yard tracks and cross-overs a lighter system is used with a 7/16-in. bronze messenger and a single 4/0, 55 per cent conductivity bronze contact wire.

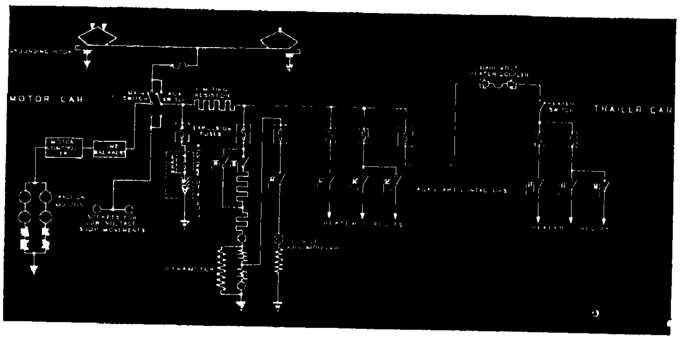

Fig. 8. Simplified diagram of car wiring; note heating circuits connected directly to 3,000-volt trolley circuit

Catenary Supports. Steel catenary supporting structures are used throughout except on the branch line from Summit to Gladstone, which is a single track line on which wood poles with steel brackets are used except at special locations where steel structures are required. The standard steel supporting structure has H-columns and either an H-beam or a latticed truss cross member, the H-beam being used up to spans of 53 ft. and lattice truss for longer spans. On tangent track the standard spacing between catenary supports is 300 ft. In general the signals and catenary system are supported on the same structures which support the catenary, as illustrated in Fig. 10.

Tie Stations and Catenary Sectionalizing. Except on the single track branch line from Summit to Gladstone, tie stations (or circuit breaker sectionalizing stations) are located approximately midway between substations, and also at or near the ends of stub-end lines. The locations of the tie stations and the distances between substations are shown on the map, Fig. 1, already referred to. At the tie stations the catenary system is sectionalized and all circuits are brought to a common bus through high-speed circuit breakers, the holding coils of which are energized from the line. With this arrangement advantage is taken of multiple feed with reduced copper losses between substations and tie stations without sacrificing selective protection of the line. All tie stations are largely automatic in function but are also under remote or supervisory control from the nearest railroad signal tower. The high-speed circuit breakers connected with circuits which are also fed at the other end from a substation are arranged so that after opening under a line short circuit or overload, they reclose automatically as soon as voltage is restored on the circuit (*i. e.*, when the circuit has been energized from the substation end by the operator at the substation, reclosing the feeder breaker). On stub-end lines which receive power at one end only, the breakers, after opening under short circuit or overload, automatically reclose three times at definite intervals and then lock out if the fault has not been cleared.

The trip points of the high-speed magnetic blow-out circuit breakers are adjustable as to current and also as to sensitivity to the rate-of-rise of the current. New features of these breakers permit increased flexibility in the rate-of-rise adjustment. Means are also provided for calibrating the breakers with low-voltage battery current (maximum, 20 amperes at 12 volts).

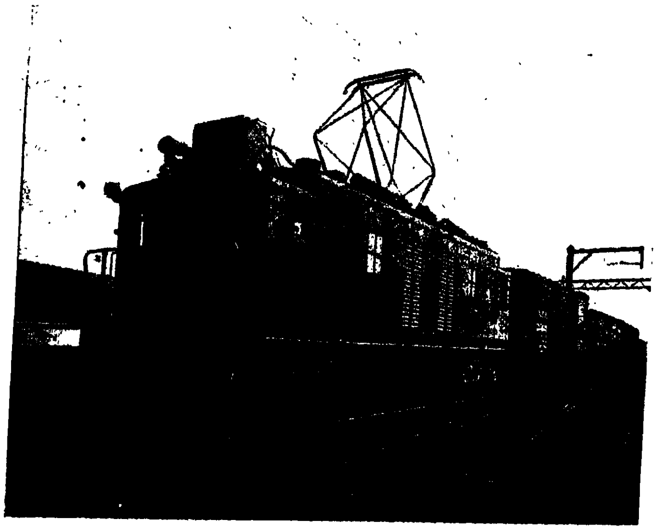

Fig. 9. Combination trolley-Diesel-battery locomotives used for freight transfer

Other Features

In connection with the electrification program a complete change in the signal system became necessary. The signals and track circuits were formerly battery-operated and the signals throughout most of the territory electrified were of the old semaphore type. All signals in the electrified zone have now been changed to colored light signals with a-c. track circuits. Impedance bonds are provided in the tracks at all signal locations. At all other points the standard track bonding consists of a single 4/0, 8½-in., gas-welded, stranded-copper, steel-terminal, U-bond at each joint on each rail.

Extensive surveys and tests were made both before and after electric operation of trains was begun to determine the points at which there might be danger of electrolytic damage to underground cable sheaths and other metallic structures, and drainage cables have been installed where they were found desirable.

Where necessary to provide adequate physical clearance, communication circuits located along the right-of-way, consisting of the railroad's communication lines and some other telephone and telegraph lines, have been moved or put into cables. Inductive interference from the d-c. power flowing through the catenary system has been practically eliminated by the use of twelve-phase rectifier transformers, d-c. smoothing reactors and resonant shunts, installed at the substations.

The mercury arc rectifiers also cause a distortion of the wave form on the a-c. supply circuits, and where the a-c. power is supplied by overhead transmission lines inductive interference in neighboring telephone circuits may be experienced unless steps are taken to guard against it. This effect can, however, be largely eliminated by proper coordination and transposing of the power circuits and the neighboring telephone circuits. This has been taken care of by the cooperative effort of the power companies and the telephone companies. No radio interference has been reported.

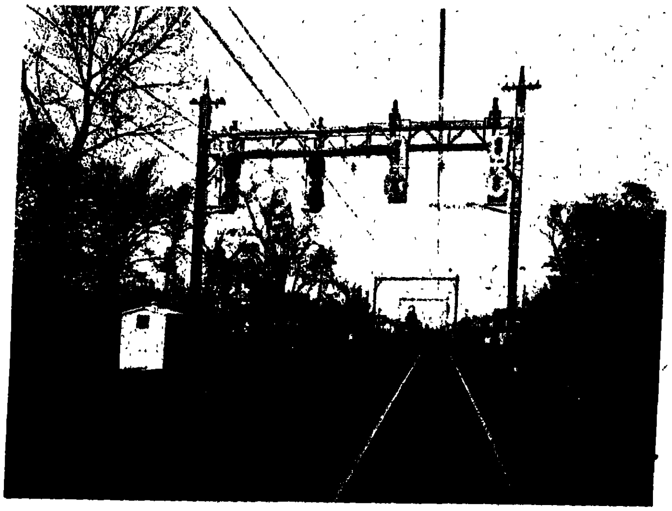

Fig. 10. Typical overhead construction on a three-track tangent section

This is the first electrification program attempted in this country in which the entire power supply for tractive purposes depends solely on the satisfactory performance of mercury arc rectifiers. Such a project would have been impossible of completion in this way had it not been for vast improvements in the design of these devices which enable them to be built for higher voltages and heavier loads than heretofore. These advances have been made possible by the intensive research and development work which has been applied to converting apparatus in general during the past few years. The installation of such a system constitutes a bold step forward in the electrification field, and its effect on future projects of this sort will be watched with keen interest.

Your Nimble Servant —the Electron

A summary of the present scientific understanding of electronic theory presented briefly in non-technical language.

By Karl Taylor Compton

President, Massachusetts Institute of Technology
Cambridge, Massachusetts

THE ELECTRON, as is commonly known, constitutes the smallest known division of matter. Science has shown it to be a peculiar combination of mass (minute though it is) and electrical charge, and that its inherent characteristics exhibit a singular combination of rotation and wave motion. All electrical phenomena are directly dependent upon the workings of countless numbers of these infinitesimal particles. A stream of them flowing along a wire constitutes a flow of electric current; millions of them boiling off hot metal filaments give us modern radio and the talkies; still more millions of them are active in our luminescent electric signs, while television is providing still another job for these "nimble servants."

In 1899 experiments on the striking luminous and electrical effects accompanying the discharge of electricity through vessels containing gases at reduced pressure led to the discovery that in these phenomena, the primary agent which we now know as the electron is a negatively electrified particle 1,846 times lighter than the lightest entity then known, the hydrogen atom, and bears an electric charge which is a natural indivisible unit of electricity. Electrons are affected in various ways by a wide variety of agencies, such as heat, light, chemical action, and shock. In some cases they are ejected from bodies spontaneously; in other cases they are pulled out by intense electrical fields. Spontaneous emission of electrons is one of the three phenomena shown by radioactive substances, and it occurs in the process of actual transmutation of one chemical element spontaneously to another.

These properties of the electron were discovered by Sir J. J. Thomson and his pupils immediately following the year 1899. About 12 years later Millikan and his pupils made much more accurate measurements of the magnitude of the electric charge on an electron. As a result of this work it may be said truly that although no one ever has seen or ever will see an electron, and although it is the smallest charge and has by far the smallest mass of anything which is known, nevertheless its mass and its charge have been measured experimentally with an accuracy far beyond that with which materials ordinarily are weighed or measured.

MAGNETIC PROPERTIES

Light produced by the motions of electrons in atoms has been found to be affected in a peculiar way by the presence of a magnet. By means of a magnetic field the light which may be given out at a certain definite wavelength and appear as a certain definite color or line in the spectrum may be split up into several components, some of longer and some of shorter wavelength, and having peculiar properties of polarization. This effect is so small that it can be observed only under the influence of powerful magnetic fields; and even then it is so small that it must be examined with a magnifying glass. This phenomenon is known as the "Zeeman effect." It has led to the proof that an electron, besides being an electric charge, also is a tiny magnet of perfectly definite strength, and that therefore the electron may be oriented one way or another by the application of a magnetic field.

Magnetic effects are produced, of course, by electric currents and any circuit in which an electric current is flowing behaves like a magnet. This suggests that every electron is really a tiny electric circuit; or, in other words, that it consists of a rotating or revolving electric charge the revolution of which is equivalent to a current in an electric circuit. This suggests that the

---

From an address delivered at a special session of the A. I. E. E. winter convention, New York, Jan. 28, 1931.

electron is a spinning electric charge, and therefore that in addition to having mass and electric charge, it has a definite magnetic moment and an angular momentum.

WAVE PROPERTIES

The electron also has the properties of a wave. The phenomenon of interference is widely known as characteristic of all types of wave motion, including light, heat, ripples, elastic vibrations, radio waves, and similar phenomena; but G. P. Thomson, son of Sir J. J. Thomson, was the first to show that when electrons pass through tiny apertures, there are phenomena of interference exactly similar to the phenomena of interference occurring when light passes through similar small apertures. This is perhaps the most striking demonstration of the fact that an electron has the properties of a wave. The same conclusion had been reached by a different interference phenomena a short time earlier by Dr. Davisson and Dr. Germer of the Bell Laboratories.

This wave nature of the electron is of a peculiar kind, in that the wave appears to be associated with it, directing it in its motion. There is a sort of indeterminism in the motion of any individual electron, but the probability or statistical likelihood of definite direction of motion can be determined from the properties of the wave which is associated with it. The wave furthermore has the peculiar property of a wavelength varying inversely as the momentum of the electron.

CURRENT FLOW EXPLAINED

Long before the existence of electrons was suspected it was found that the amount of current flowing in any given metallic circuit was exactly proportional to the voltage. This is the relationship as stated in the familiar Ohm's law. From the scientific standpoint it has been of great interest and until recently, a great puzzle as to just what determined this proportionality between current and voltage. According to the presently accepted ideas the more loosely bound electrons in the atoms which make up the metal are, under the influence of neighboring atoms, detached from their original parent atoms and are free to move somewhat at random throughout the metal. This motion is governed in part by temperature, since, on the average, the higher the temperature the more rapidly these electrons will move. The motions of the electrons are not all alike in velocity or direction, but are distributed at random according to a certain law of probability given by what is known as the Fermi statistics. These electrons are interfered with in their motion in various directions by collisions with each other or with atoms. When a voltage is applied, however, there is a constant force impelling them on the average to drift in the direction of the voltage, and it is this drift which constitutes the electric current.

In the earlier theories, the collisions just referred to were conceived of as if with atoms which behaved like hard, resilient spheres; but this was obviously too crude an approximation to fit the facts; an apparently satisfactory picture is the recent one credited to Sommerfield and his pupils, according to which the motions of electrons in metal are governed by the interference of their waves in passing through the lattice-like structure of the atoms. According to this idea the deflection of an electron at collision means simply that the electron wave has been bent or diffracted out of its original path.

All this has brought about a very close analogy between some problems in electrical conduction and some problems in the propagation of light; and underlying this whole subject is a new branch of mechanics called "quantum mechanics." According to quantum theory, mechanical or electrical phenomena involving particles of electronic or atomic dimensions have to be treated by "wave mechanics," whereas phenomena occurring between larger bodies of a tangible size are treated by the ordinary electrodynamical methods; in other words, ordinary electromechanical concepts represent the special form which the quantum mechanics takes when applied to large bodies.

ELECTRON MOTION IN GASES

Conduction of electricity through gases, which was the phenomenon that originally led to the discovery of the electron, still supplies perhaps the most complicated and intriguing problems in electricity. In such phenomena there must be considered the electron which is moving rapidly under the influence of the applied voltage and making frequent collisions with gas molecules; there must be considered also the heavy positive ions which result when electrons are knocked out of molecules, and which move relatively sluggishly in the opposite direction. Due to concentrations of one or the other kind of these electric charges in different parts of the gas, there is produced a very irregular distribution of the voltage through the gas, which accounts for some of the striking optical and electrical peculiarities of gas discharges.

Another peculiarity of electric currents in gases is that as the current increases, the resistance of the gas decreases. Because of this fact electric currents in circuits containing a path through a gas show many remarkable peculiarities, such as electric oscillations and discontinuous changes. Familiar forms of these phenomena include sparks, electric arcs, and the great variety of sign-lighting devices, such as neon tubes and mercury arcs. Lightning and aurora borealis are examples of such currents in cosmic phenomena.

Another interesting phenomenon is the thermionic emission of electrons. As already mentioned, the average speed of electrons in metals is controlled by the temperature of the metal, and if this temperature is raised sufficiently high an appreciable proportion of the electrons which strike the surface of the metal from the inside will be moving fast enough to escape entirely from the surface in spite of forces which tend to pull them back. It is these evaporated electrons which constitute the electric currents in radio tubes. There the hot filament is the source of electrons which are evaporated into the surrounding space and are drawn to the plate subject to the controlling action of the voltage impressed upon the intervening grid.

ELECTRONS RESPOND TO LIGHT

When light, particularly ultra-violet light, falls upon metals, electrons may be ejected from the metals. The stronger the light the more electrons are ejected; and the shorter the wavelength of the light the greater the velocity with which they emerge. This phenomenon was accidentally discovered nearly 50 years ago, although its exact nature was not then understood. One of the most important contributions which Einstein has made to science was brought out in 1905 in his application of the quantum theory to explain the relation between the wavelength of the light and the velocity of ejection of the electron.

At the present time these so-called photoelectric currents are perhaps the most sensitive means in existence for the detection of light. They are used in stellar photometry and are the heart and soul, so to speak, of all television apparatus. This photoelectric phenomenon, too, is capable of a great variety of applications. For example, it permits electrical registration to be made of visitors entering a door; it permits automatic sorting of cigars, fruit, cloth, or other objects according to color; it enables the U. S. weather bureau to make a continuous electrical record of the brightness of sunlight; it performs innumerable important laboratory functions.

THE ELECTRON IN CHEMISTRY

A most interesting series of lectures was delivered at the Franklin Institute in Philadelphia a few years ago by Sir. J. J. Thomson concerning the electron in chemistry. It has become evident now that the so-called "chemical forces" or valence forces which the chemist has used to account for the sticking together of atoms to form all the multitudinous varieties of molecules are nothing more or less than electric and magnetic forces existing between atoms and caused by the space distribution motion of electrons. Thus the whole field of chemistry on the interpretive side is turning into a study of electronic effects.

One of the most effective ways to investigate any object which cannot be seen or handled is to stir it up in some way and then try to observe and interpret what happens; this is exactly the process of research in modern atomic physics and interpretive chemistry. Atoms and molecules can be stirred up in a variety of ways—by heat or by electrical currents. Emission of light is the most frequently observed result of such agitation and from a spectrum study of that light it is possible to infer a great deal as to what went on in the atoms and molecules themselves. In principle this method has been the basis of all present knowledge of the structure of atoms and molecules and the fundamental electrical nature of matter.

Fundamental to, and inherent in, every aspect of mechanical and electrical properties of matter, there is the electron—always present and always active, and thus justifying perhaps the title of this article, "Your Nimble Servant, the Electron."

◆ ◆ ◆

Reducing Noises From Power Transformers

With a view to their reduction, objectionable noises have been under investigation in various parts of the country during the past few years. In line with such work, thoughtful attention is being given to the reduction of unnecessary noises in electrical machinery and apparatus. Causes of transform r noises have been determined and together with means suggested for control are described here.

By R. B. George
Member A. I. E. E.
Westinghouse Electric & Manufacturing Company
East Pittsburgh, Pa.

VIBRATION is the chief cause of the noises emanating from power transformers, since rotating parts, the most prevalent sources of noises in all machines, are completely absent. Electromagnetic pulsations set up by the alternations of the current in transformer windings give rise to mechanical vibrations. An impulse from each half-cycle of this current causes a fundamental frequency of vibration double that of the circuit in which the transformer is connected. Thus the

---

From "Power Transformer Noise, Its Characteristics and Reduction" (No. 30-178), presented at the A. I. E. E. Southern District meeting, Louisville, Ky., Nov. 19-22, 1930.

fundamental frequency of vibration in a 60-cycle transformer would be 120 cycles per second. These vibrations usually originate in the core-and-coil structure and are transmitted by the oil to the tank wall whence they are passed on into the outside air. Resulting sound emission is in the nature of a continuous hum of comparatively definite pitch and in most cases extremely annoying.

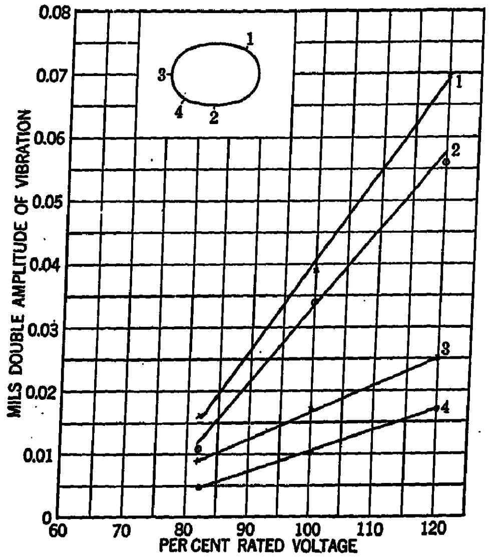

Fig. 1. Effect of voltage variation upon amplitude of transformer tank-surface vibration

Results of a theoretical investigation made to determine the different force components in transformers which might cause vibration show that:

1. The force between the winding and the core is an attractive force, but when solid insulation is wedged in between the coils and core, this force is not serious.
2. There is an attractive force which acts at each joint of the core and tends to make the iron circuit continuous; this force is directly proportional to the cross-section area and to the square of the magnetic density.
3. There are between parallel laminations of the core, forces of repulsion arising from like poles induced in adjacent ends of parallel laminations.
4. There are electrodynamic forces between the coils. These forces are attractive between coils of the same winding and repulsive between coils of different windings. They are proportional to the square of the ampere-turns per group.

In addition to the forces just enumerated, metal plates, tie rods, radiator tubes, structural steel parts, or other members, may be resonant and serve as unexpected sources of noise which are sometimes exceedingly troublesome. Power transformers having tanks with large areas exposed for radiating sound, however, usually have natural periods of vibration below 60 cycles.

To deal effectively with the noise problem, the sound analyzer developed by J. P. Foltz ("Study of Noises in Electrical Apparatus" TRANS. A. I. E. E., July 1929) was used in these investigations. The instrument consists principally of amplifiers and filter circuits which can be set to eliminate all but a certain frequency. The noise to be analyzed is picked up by a microphone and passed through the filter circuits. The setting of the filter-circuit condenser indicates the frequency of the sound measured, and a meter indicates in dynes per sq. cm. the intensity of the sound at that frequency.

For comparing sounds with reference standards, this analyzer is independent of the human ear and therefore leaves nothing to the personal judgment or imagination of an individual listening to a telephone receiver. When it is desired to measure mechanical vibration, a calibrated phonograph pick-up is substituted for the microphone; then the sound analyzer can be used to measure the frequency and amplitude of vibration.

Vibration amplitude and frequency measurements were made on the tank surfaces and core-and-coil parts of a number of representative sizes of completely assembled transformers at no-load and at different voltage values. These tests were to determine the effect of line voltage regulation on the amplitude of vibration and the corresponding sound intensity. Fig. 1 shows some of the results of tests on a large transformer at the elevation of the center of the core; locations of the points are indicated on the plan view at the upper left hand corner of the figure. These curves are approximately straight lines, indicating that the vibration component due to voltage regulation can be considered directly proportional to the per cent change in line voltage within the operating range of the transformer. The ratio varies with different designs but is usually of the order of 30 per cent change in sound intensity for 10 per cent change in primary voltage at no-load.

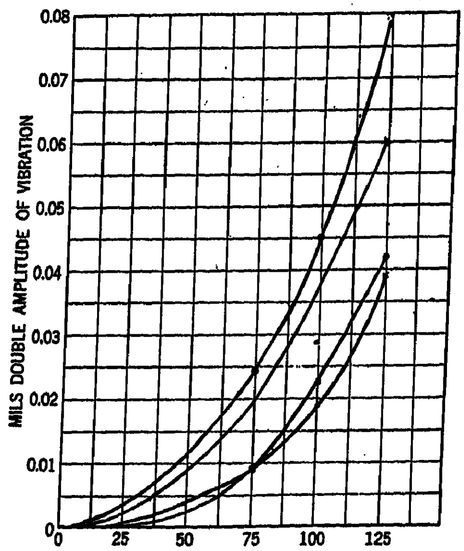

Fig. 2. Effect of load current upon amplitude of transformer tank-surface vibration

Tests were made also on the core-and-coil parts of transformers to determine the characteristics of those parts which act as sources of noise due to load currents in the windings. These tests were made with one transformer winding short-circuited and sufficient voltage impressed on the other winding to obtain the desired values of load current. Vibration amplitudes and frequency measurements were taken for each load. There were similar tests on completely assembled power transformers where surface vibration measurements were made also on the tank and other exterior surfaces. Results of tests on one of these transformers are shown in Fig. 2. Measurements were taken at four representative points at different elevations on the side of the transformer. It may be observed that the amplitude of vibration varies approximately as the square of the load current.

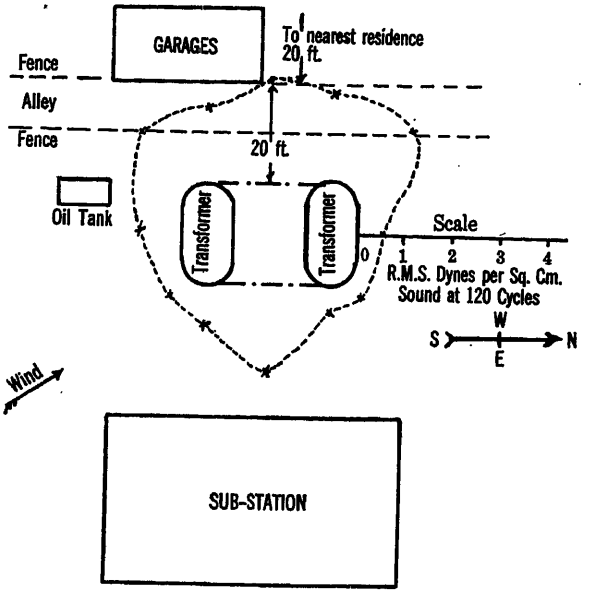

Fig. 3. Intensity distribution of 120-cycle sound measured at points 20 ft. from transformers. Reflections from nearby buildings and effect of wind may be noted

Results of frequency analyses at the points of maximum amplitude of vibration observed on the load and voltage tests showed that different harmonic frequencies were present under both sets of conditions. All of these harmonic frequencies were exact multiples of the 60-cycle power frequency. However, vibration amplitudes at frequencies above 120 cycles were usually so small as to be negligible. The test range included frequencies up to 3,000 double vibrations per second, but no vibrations were noted at frequencies above 600 cycles.

Another investigation was made to determine the distribution of sound at 120 cycles measured at a distance of 20 ft. from the transformers at the substation shown in Fig. 3. Since there are two transformers at this station, lines were drawn between them, and the resulting area treated as the noise source. The curve is plotted in modified polar form with reference to the tank wall and the two connecting lines described above. At a distance of 20 ft., the average vibration intensity was found to be 1.142 dynes per sq. cm., the minimum 0.48, and the maximum 2.06. This results in a maximum-to-minimum ratio of 4.3 to 1. Reflections from the substation building and the neighboring garages are evident, as is also the effect of wind, in the upper right hand corner of the figure. Both transformers were large three-phase units, carrying at the time of test about 84 per cent rated load at about 97 per cent rated voltage.

Fig. 4 gives another interesting illustration of the effects of the acoustic conditions at the substation; a smooth-finish, plastered wall was located diagonally as shown on the upper side of the figure and a hard wall of steel plates was located symmetrically on the opposite side of the transformer. The inner curve shows the distribution of vibration of the tank wall at 120 cycles; the outer curve shows the distribution of the intensity of sound at 120 cycles and at a distance of 42 in. from the tank wall. Both curves are plotted in modified polar form with reference to the tank wall. The average 120-cycle intensity was observed to be 0.385 dynes per sq. cm., the maximum 0.685, and the minimum 0.31, giving a maximum-to-minimum ratio of 2.2 to 1.

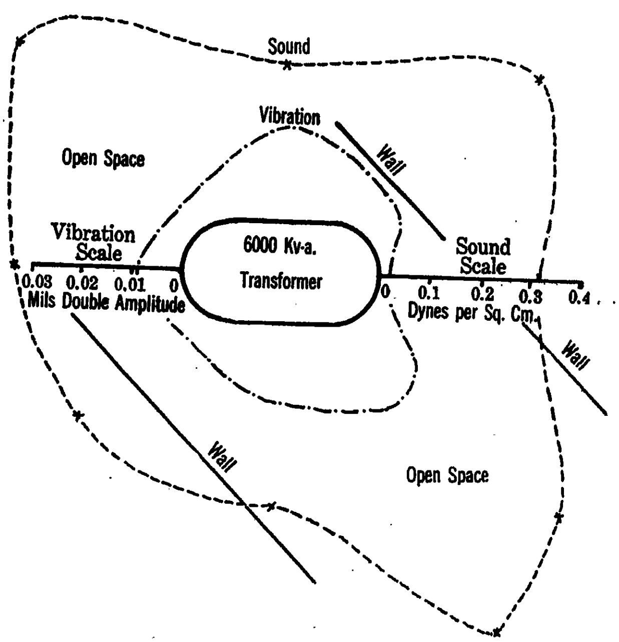

Fig. 4. Curves showing the effect which enclosing walls have upon the intensity distribution of 120-cycle sound from a transformer

Conclusions

These surveys mark an important advance in the knowledge of power transformer noise characteristics and magnitudes. The sound intensities are not uniform in all directions, the acoustic conditions at the substation playing an important part in the final distribution of sound.

The very nature of a transformer makes it always produce some hum, but for operation near hospitals or in residential districts this hum can be reduced by the following expedients:

(1) Using additional iron in the core in order to secure low magnetic density. This also means additional copper and a more expensive transformer.

(2) Stiffening the bracing and supporting parts to reduce vibration and in some cases adding damping devices to change the natural period of vibration.

(3) Adding cushions or padding between parts of the transformer.

(4) If sufficient area is used to prevent crushing, cork pads can be used under transformer tanks in indoor vaults. Arbors, hedges, shrubbery and trees are very effective for absorbing sound from outdoor substations.

What of Surplus Power?

Surplus power, natural by-product of the electric service industry, should be developed and utilized in industrial processes under a definite program. A plan is proposed whereby the useful output of existing electric generating equipment may be increased as much as 30 per cent; improvement resulting in system load factor would permit economic construction of plants still more efficient, thus contributing constructively to the cycle.

By Farley G. Clark
Fellow A. I. E. E.

Consulting Engineer
Toronto, Ontario

MANY ATTEMPTS have been made to dispose of seasonal and off-peak power, but thus far the only reasonably successful scheme brought out is interconnection. This plan, however, reacts more toward the saving in reserve generating equipment than in the transfer of energy. The proposal for the utilization of surplus power as introduced in this article differs from others in that the rate of power supply is under the control of the power company, and as the total system load demands can be varied at will. Surplus power can be used in this way for a number of electrochemical and electrothermal processes and will result in markedly reduced costs for a great many commodities. For example, it is possible to manufacture illuminating gas at a cost that would compare favorably with the cost of natural gas at the end of a long pipe line.

For the purposes of this article, surplus or off-peak power will be defined as all power producible from the serviceable capacity of generating equipment that is not required to meet all other demands. The part of this surplus required for the proposed disposal is that portion which would result from the daily generation of a quantity of the surplus energy agreed upon as being available and usable.

Before the proposal has value, the utilities must agree that they have and long will continue to have this spare capacity available. They must assure themselves that the shape of the annual load-duration curves, which has not changed materially during 30 years except as to growth upward, is not likely to change its characteristic shape during the next 20 years. They must be assured that the day of maximum output, which is the main limitation, will continue to have the characteristic load curve which has been typical of the past 20 years of growth.

To avoid complications hydroelectric power is eliminated from consideration. Whenever kw-hr. can be stored in a reservoir the proposal is not attractive; but if steam reserves are needed, the situation becomes favorable.

POSSIBLE RATE REDUCTION

This surplus obviously is nothing but a potentiality; it is not demanded and it cannot be sold under existing terms and conditions; or if it is to be sold or profitably used, the terms must be modified to meet the new conditions. In fairness to the utilities, however, it will be necessary to state that never before have they been called upon to deal with the matter in any like manner or under the conditions proposed in this discussion.

If assumed premises are right and the conclusions are in accordance with the facts, the price of this surplus energy can be made sufficiently low to attract the attention of many possible users most of whom cannot avail themselves of it without becoming purchasers of quantities of the regular high-priced product. The proposal holds out no hope for an early reduction in standard rate schedules, a general reduction of which will come when the use of this surplus has so increased the capacity-use of equipment that more efficient and cheaper generating plants can be built.

During the early stages of development, it is essential that every cost advantage maturing in favor of the surplus generation should be accredited to it. For example, assume that a purchaser of surplus energy asks for 192,000 kw-hr. per day on a 20-year contract, and will allow the utility to vary at will the rate of delivery between 0 and 10,000 kw. Nine out of ten utilities having a maximum yearly peak of 100,000 kw. or more can meet this requirement and establish a new increment fuel rate about 5 per cent lower than their normal rate.

Some advantages of this plan are:

1. It would be unnecessary to operate or maintain reserves within the capacity of the superimposed load. It is obvious, therefore, that no part of the generating plant capital is involved in the supply of this surplus energy.
2. A regulable means would be provided for setting the total station load nearer to the point of greatest economy.
3. A means would result for absorbing the fluctuations of the normal load.
4. The load factor of the system would be increased.

The actual cost of this energy, when, as, and if generated, is the total production cost for any given period less the estimated cost during the same period for the other or normal load. There may be some difficulty in devising an accounting system to satisfy public service commissions, although it is expected to indicate costs which will provide sufficient latitude for the satisfaction of all concerned.

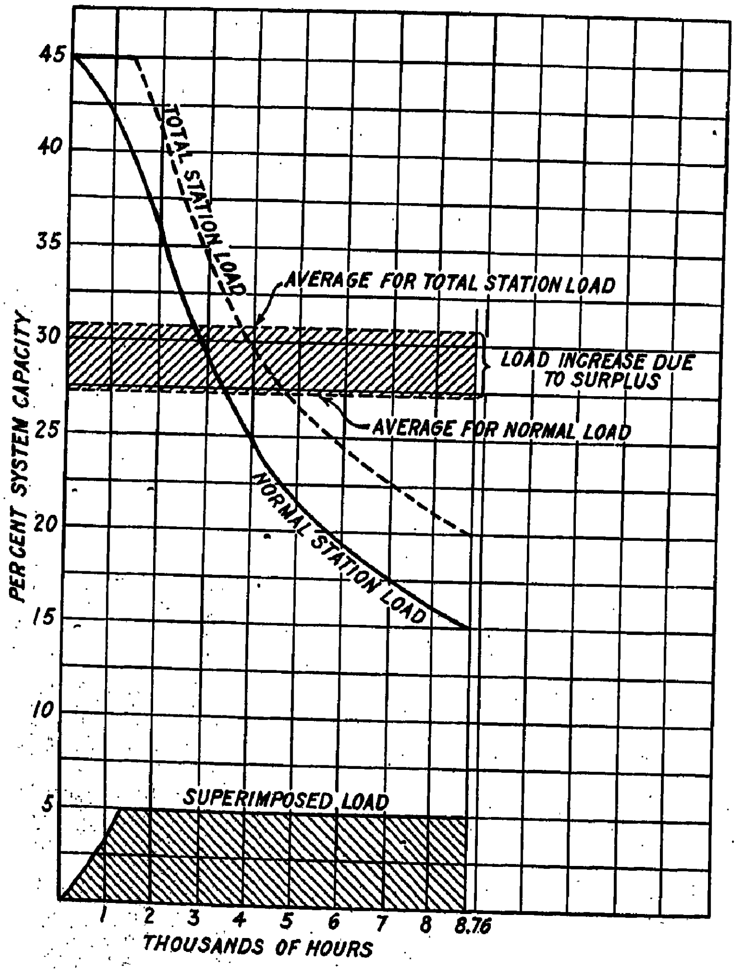

Fig. 1. Cumulative annual curves showing method of superimposing "surplus" load upon normal station load without increasing station demand

Surplus Power Now Available

Magnitude of the proposal can best be appreciated by calling attention to a few statistics for 1930 and estimates for 1940 with the trend discounted by reason of the existing depression.

According to statistics, there was installed in 1930 in the United States, a total steam-electric generating capacity of approximately 30,000,000 kw. in stations having a yearly output of about 60,000,000,000 kw-hr. During the period from 1900 to 1930 the maximum-load demand has increased seven times and the annual power output eleven times. On the basis of these facts it seems reasonable to predict a total installed steam-electric generating capacity of at least 45,000,000 kw. by 1940, and an annual power output of 100,000,000,000 kw-hr.

According to the calculations upon which this proposal is based, surplus power could be produced profitably on the basis of an annual output of at least 30 per cent of the present annual output; this means an output of 18,000,000,000 kw-hr. based upon 1930 statistics, and 30,000,000,000 kw-hr. based upon 1940 predictions.

Table I gives data for a suggested annual distribution of load by which this 30 per cent of surplus power can be furnished. Resulting improvement in load factor also is shown. It may be noted that according to this set-up the power is made available for 8,540 hr. out of a total of 8,760 hr. in the 365 days of a year. This arrangement provides for shutting down the surplus power supply during very high peak loads so that the maximum demand on the system is not increased.

TABLE I—SUGGESTED DISTRIBUTION OF LOAD FOR FURNISHING 30 PER CENT SURPLUS POWER OUTPUT

	1930		1940	
	Annual Service hours	Surplus power output in kw.	Annual service hours	Surplus power output in kw.
1st 5 per cent	8,540	360,000	8,540	600,820
2nd 5 per cent	8,322	380,500	8,322	634,200
3rd 5 per cent	8,059	403,000	8,059	671,500
4th 5 per cent	7,708	428,000	7,708	713,340
5th 5 per cent	7,271	457,200	7,271	761,040
6th 5 per cent	6,745	463,200	6,745	815,390
Normal load factor	0.225		0.254	
Load factor with 30 per cent surplus power	0.263		0.329	

In Fig. 1 is shown how this surplus load would be superposed on the normal system load for a typical power system. Fig. 2 shows how the load might be distributed

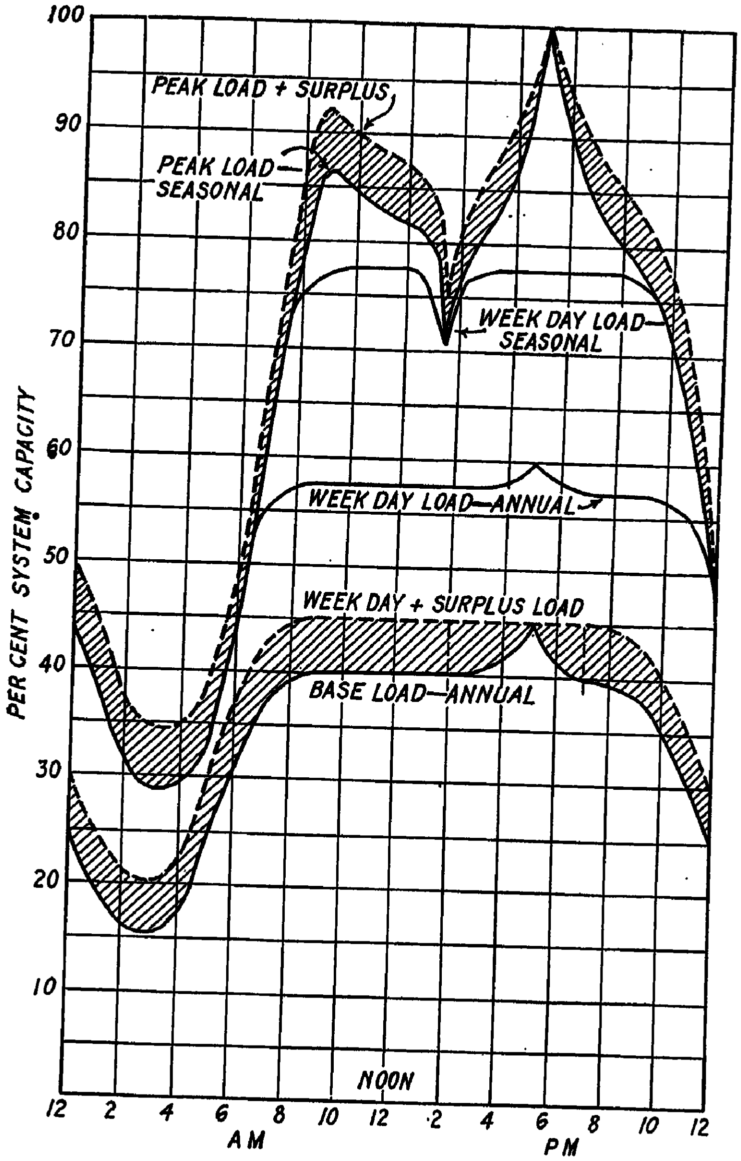

Fig. 2. Typical distribution of annual system peak load among system generating stations showing method of carrying "surplus" load in addition

among the various generating stations of a typical system, and also the cutting off of this load during system peak hours. The greater part of the surplus will be furnished from the most efficient apparatus whose capacity factors will be materially increased.

Base-load apparatus now operating at from 50 to 60 per cent load factor then will operate at from 70 to 80 per cent, a loading that will make it possible to revolutionize the design of generating plants. There will be no question about the advantages of high pressures and temperatures, steam extraction and reheating, and the leviathan prime movers no longer will be needed to save space and meet the conditions of variable load. This should make it possible to standardize the generating equipment and promote quantity production with a tremendous saving in development costs.

It is possible to forecast generating plants of relatively simple design with one steam generator for each prime mover and with most of the equipment in the open air. It is reasonable also to anticipate the use of the double thermodynamic cycle. The mercury boiler and turbine may no longer be a curiosity and there may be competition from other high-boiling-point liquids having suitable vapor tensions.

Those who can remember the "modern" power plants of 1900 with its wonderful performance of 4 lb. of coal per kw-hr., and who know that during the last decade the coal rate of the latest equipment has dropped from 2 to 1 lb. per kw-hr., will not condemn the suggestion that it may be 0.5 lb. per kw-hr. by 1940.

PRODUCTION COSTS

Relative to what this surplus energy will cost, it is but fair to state that several complications are to be faced. Familiarity with hundreds of computations, some of which are based on most reliable data, compels the conclusion that no two plants will produce similar results. The best that can be done is to portray what is considered to be an average. Systems most favorable to the surplus load will have costs averaging lower, and those unfavorable will have costs higher than those to be given.

It is axiomatic that the first 5 per cent addition of surplus will produce the greatest immediate saving, also that the saving will increase proportionally with an increase in the cost of coal. Additional increases in surplus load produce less and less saving until a point is reached where by reason or lower capacity-use the increase in the cost of fuel offsets the efficiency increase.

Admitting the pictorial method used in dealing with a matter requiring knowledge of many local conditions for any real accuracy, what are considered to be average costs are tabulated for the 18,000,000,000 kw-hr. available in 1930 and the 30,000,000,000 kw-hr. to be available in 1940. Assumptions upon which Table II is based are as follows:

1. Coal of 13,000 B. t. u. per lb., at $4.00 per ton.
2. Coal cost is 80 per cent of the total production cost.
3. The actual cost is 110 per cent of the production cost.
4. All fuel saving on normal load is credited to the surplus load.
5. Charges for capital are omitted.

TABLE II—ESTIMATED COST OF SURPLUS POWER COST IN MILLS PER KW-HR.

Surplus	1930	1940
1st 5 per cent	0.4	0.25
2nd 5 per cent	0.6	0.35
3rd 5 per cent	0.9	0.50
4th 5 per cent	1.5	0.75
5th 5 per cent	2.3	1.25
6th 5 per cent	3.5	2.00
Average for 30 per cent	1.5	0.85

Assuming that this portrayal will appear incredible matters may as well be made worse by suggesting that if by 1940 there is in use some 5,000,000 kw. of double-cycle apparatus, the first 10 per cent addition of surplus will be free of cost, and the average cost for the 30 per cent surplus will be less than 0.5 mill per kw-hr. It should be pointed out that there is a somewhat perplexing question regarding fixed charges for new and possibly more expensive equipment, such as the mercury-cycle boiler and turbine. This more efficient apparatus might be warranted by the surplus, but not by the normal load. Some attempt has been made to allow for this in the table of costs.

How Surplus Power Can be Used

As previously mentioned, this proposal is based upon the absorption of surplus energy in electrochemical and electrothermal processes. Electrochemical processes will come first since they are adapted to the requirement of regulation and of intermittent use. Electrothermal processes are best adapted to the use of night and week-end power. There are but few electrochemical processes now capable of adaptation to this kind of use and only one of them is immediately ready. There is much to warrant the expectation that when the advantages of this cheap power become well known, a way will be found to adapt many more processes to its use—at least to some extent.

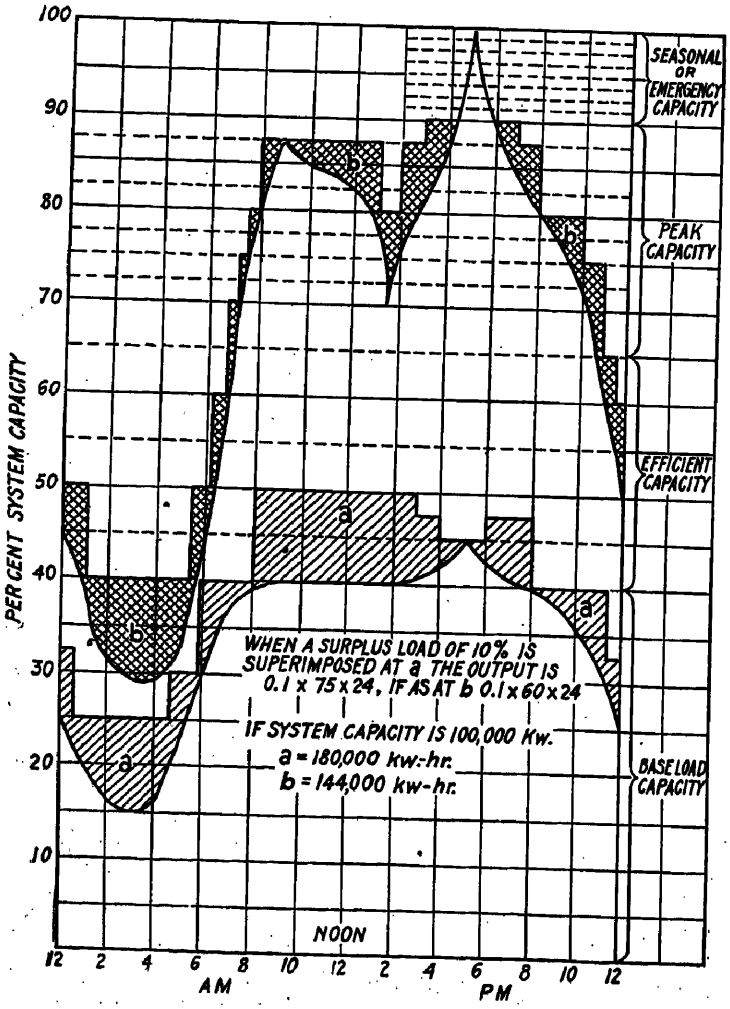

Fig. 3. Method of improving station efficiency by superimposing a "surplus" load equivalent to 10 per cent of the system capacity

Electrolytic cells for the decomposition of water by electric current have been in use for many years. There are several types that will meet the technical requirements of intermittent and variable use of energy. In addition, there is reason to believe that salt cells equally suited to the use of off-peak power will be available shortly. From an economic point of view, first cost and maintenance are of great importance and this narrows the choice of types of cells. However, a careful survey of all types of cells capable of using off-peak power leads to the conclusion that water cells will be of greatest value, salt cells next in value, and that there are other possibilities relating mostly to the electrolysis of organic compounds.

Cost of Many Products Reduced

Without reaching very far into the field of synthetic chemistry and by just touching upon the metallurgical possibilities, a hasty survey reveals some of the possibilities, for it is certain that no matter how great the quantity nor how cheap this surplus energy may be, it will not be used unless profit results. Assume that the materials of manufacture available are air, water, coal, salt, oil, off-peak energy, and energy at standard rates. As products then:

1. Nitrogen can be obtained from air by burning out the oxygen with hydrogen.
2. Water and off-peak energy will produce hydrogen and oxygen.
3. From coal will be obtained pure carbon, carbon monoxide, and carbon dioxide. By use of the coke oven, coke and many hydrocarbon by-products can be made.
4. Salt and off-peak energy will produce chlorine, caustic soda, and hydrogen.
5. From oil, gas and many hydrocarbons can be manufactured.

Well-known chemical processes and usable catalytic reactions are available to convert these materials into a variety of products which can be used in the district in which they are made. Many of these dependent industries will be new to the district, bringing to it an increase of population; all will require more or less power at the standard rates.

The list of products possible of manufacture is too formidable to be reproduced here; by way of illustration only a few are mentioned. Costs given represent the total estimated manufacturing costs:

1. Hydrogen at 20c. per M. cu. ft.
2. Oxygen at 20c. per M. cu. ft.
3. Nitrogen at 15c. per M. cu. ft.
4. Carbon monoxide at 20c. per M. cu. ft.
5. Carbon dioxide at $5 per ton.
6. Chlorine gas at 0.5c. per lb.
7. City gas of 560 B. t. u. at 25c. per M. cu. ft.
8. Caustic soda at $20 per ton.
9. Carbon black at 3c. per lb.
10. As examples of final products may be mentioned synthetic ammonia and city gas.

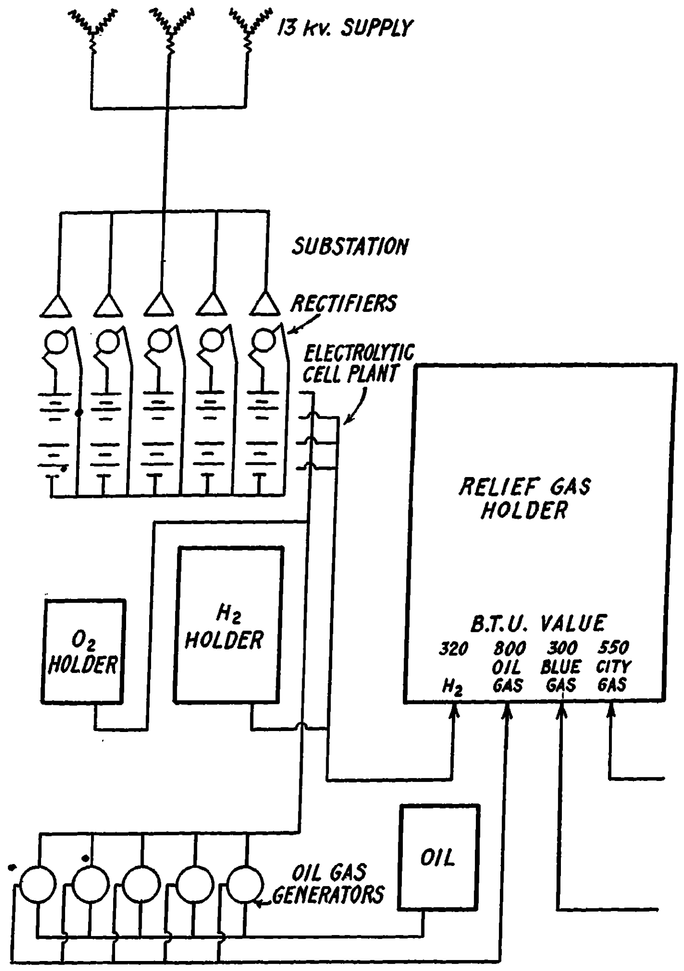

Fig. 4. Schematic diagram of a plant designed to absorb surplus electric energy in the production of gas

It is a well-known fact that when hydrogen costs 40c. and nitrogen 20c. per M. cu. ft., they aggregate 60 per cent of the cost of ammonia when produced at $70 per ton. It is reasonable to assume, therefore, that ammonia could be produced for $50 per ton when manufactured from constituents made from surplus power.

It is known also that 250 cu. ft. of oxygen and 5 gal. of oil of 160,000 B. t. u. per gal. will produce 1,000 cu. ft. of 800 B. t. u. gas and this can be diluted by adding hydrogen or blue gas (uncarbureted water gas). With oil at 4c. per gal., 500 cu. ft. of oil gas and 500 cu. ft. of hydrogen will produce 1,000 cu. ft. of 560-B. t. u. gas at less than 28c. per M. cu. ft. in the holder. Natural gas of 1,100 B. t. u. must be sold at 40c. per M. cu. ft. at the end of the pipe line to compete with this cost.

Oxygen always can be used with coke and water to produce a metallurgical reducing-gas mixture, or it can be used for air enrichment in the blast or open-hearth furnaces, when it can be had cheaply enough. Hydrogen is a fuel gas and also a reducing gas and can also be used in metallurgy when its cost is low enough. When the availability of these gases in large quantity is assured and their cost becomes lower than 35c. per M. cu. ft., they will find a market by reason of the economies their use will produce. This market will enlarge as the price of the gas lowers. If the surplus energy costs shown in Table II are put into effect and no better apparatus than that now available is used, oxygen and hydrogen can be sold profitably at 25c. per M. cu. ft. in 1932 and at 20c. per M. cu. ft. or less in 1940.

All estimates of cost have been based upon the use of new equipment for converting a-c. to d-c. energy. The cost of complete plants to furnish oxygen and hydrogen at uniform hourly rates from surplus power are estimated as shown in Table III.

TABLE III—ESTIMATED COSTS OF COMPLETE PLANTS FOR FURNISHING OXYGEN AND HYDROGEN BY THE USE OF SURPLUS POWER

Input capacity of plant in kw.	Load factor	Cost per kw.
10,000	0.90	$50.00
20,000	0.85	47.50
30,000	0.80	45.00
50,000	0.75	37.50
100,000	0.70	35.00

Substitution of mercury arc rectifiers for motor-generators would lower the cost and there always is the hope that some cheap and effective form of commutating device or electrolytic rectifier may be invented that would deliver pulsating direct current. If apparatus of this type could be obtained at about $5 per kw., oxygen and hydrogen each could be produced for about 10c. per M. cu. ft.

WHAT SURPLUS POWER NOW AVAILABLE WILL DO

It may be appropriate at this point to give an idea of what all the surplus energy alleged to be available would do in terms of products:

1. Each a-c. kw-hr. will produce about 9 cu. ft. of gas, of which 6 is hydrogen and 3 oxygen.
2. The 3 cu. ft. of oxygen with coal and water, in the Bosch process, will produce 12 cu. ft. of hydrogen.
3. One cu. ft. of hydrogen with air and heat will deliver two cu. ft. of nitrogen.
4. The 18,000,000,000 kw-hr. estimated as available in 1930 therefore would produce 108,000,000 M. cu. ft. of hydrogen and 54,000,000 M. cu. ft. of oxygen.

The oxygen could be sold at cost. The hydrogen would permit the manufacture of about 1,200,000 tons of synthetic ammonia containing nearly 1,000,000 tons of fixed nitrogen. If instead the gases were used with oil to make 555-B. t. u. city gas, there would be required about 1,062,500,000 gal. of oil and the hydrogen, and 108,000,000 M. cu. ft. of blue gas. The total annual output of city gas would be 432,000,000 M. cu. ft.

Excepting only the use of the gases in metallurgy, the manufacture of fixed nitrogen and fuel gas are the two least remunerative uses for the gases. They have been mentioned because the market for both is large and demonstrates that there need be no delay in putting off-peak capacity to work.

Consider, as a further example of what could be accomplished, that a company were to construct a plant for manufacturing gas by the use of surplus power as outlined in this article, and at the same time build an electric plant especially adapted for supplying such power in addition to its regular load. Assume, for the sake of example, that the output of the electric plant is rated at 200,000 kw., allowing 10 per cent spare capacity to meet the necessity for continuous service. Such a plant could be built for 80 per cent capacity-use and the energy taken by the electric system as base-load power would be restricted to 60 per cent load factor as being sufficient to best meet the requirements of that system. The cost of such a plant would be $100 per kw., or a total cost of $20,000,000 for the 200,000-kw. capacity. This low plant cost would be due to the simplicity of design possible with high-load-factor apparatus. Fixed charges on such a plant would be 12 per cent, thus providing for a 20-year replacement period.

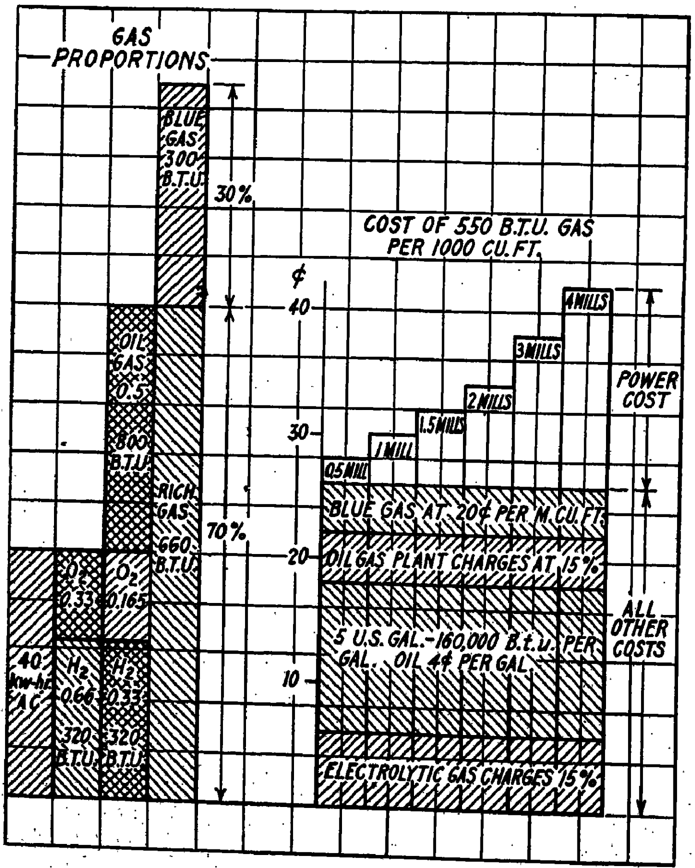

Fig. 5. Chemical composition and costs of gas produced from surplus electric energy. It may be noted that with each successive 5 per cent increment in surplus power used, the cost per kw-hr. increases from 0.5 mill to 4 mills

TABLE IV—GAS PLANT COSTS

Electrolytic Plant		
60,000-kw. converting plant @ $20		$1,200,000
55,000-kw. cell plant @ $20		1,100,000
Gas holders, 3,000,000 cu. ft.		400,000
Total		2,700,000
Fixed charges at 15 per cent		405,000
Products		
Oxygen	1,051,200 M. cu. ft.	
Hydrogen	2,102,400 M. cu. ft.	
Total	3,153,600 M. cu. ft.	
Operation		
350,400,000 kw-hr. @ 1.76		616,704
Operation and maintenance		50,000
Production cost		666,704
Fixed charges		405,000
Total cost for 3,153,600 M. cu. ft.		1,071,704
Cost of oxygen and hydrogen per cu. ft.	.34c	
Gas Plant		
Gas plant including holders		3,000,000
Fixed charges at 15 per cent		450,000
Operating Costs		
1,051,200 M. cu. ft. oxygen		357,235
21,024,000 gal. oil at 4c		840,000
Operation and maintenance		40,000
Cost of 4,204,800 M. cu. ft. 800 B. t. u. gas		$1,238,105
Cost per M. cu. ft.	29.4c.	
Add 2,102,400 M. cu. ft. hydrogen		714,460
Cost of 6,307 M. cu. ft. 660-B. t. u. gas		1,952,664
Cost per M. cu. ft.	30.9c.	

At an annual load factor of 60 per cent, which is assumed for the base load, the energy output for the electric system would be 1,051,200,000 kw-hr. At this load factor the thermal rate would be about 12,500 B. t. u. per kw-hr., which can be taken as equivalent to one pound of coal. Coal rate is assumed to be 80 per cent of the production cost, which is about 95 per cent of the total cost. Taking coal at $4 per ton the energy cost would be 2.64 mills per kw-hr. The price which ought to be obtained would therefore be about 5 mills per kw-hr. The plant, however, would be loaded to 80 per cent load factor, as the gas plant would be able to use the surplus power in gas manufacture. Based on this load factor the annual output would be 1,401,600,000 kw-hr., and the surplus power output 350,400,000 kw-hr.

The thermal rate based on 80 per cent capacity-use would be 11,500 B. t. u. per kw-hr. This low thermal rate would be obtained by the use of high pressure, high temperature, steam extraction, and reheating. On the basis used for the 60 per cent capacity, the cost of this energy would be 2.42 mills per kw-hr. It is estimated that 75 per cent of this output would be sold at 2.64 mills, leaving the net cost of the surplus as 1.76 mills per kw-hr.

To raise the load factor of the electric system from 60 per cent to 80 per cent, would require a gas plant capable of absorbing about 60,000 kw. Fig. 4 shows a schematic diagram of such a plant. Cost estimates for this plant and its operation are shown in Table IV.

In Fig. 6 is indicated the cost of 800-B. t. u. oil gas when oxygen and oil are used, and the cost of 660-B. t. u. mixed gas when the hydrogen also is used. The costs are related to the cost of the surplus energy.

The feasibility of utilizing surplus power by the method proposed seems to be well established by the examples given. From the standpoint of the power companies, adoption of such a plan would be quite advantageous and it is obvious that the general public would benefit as well through the lessening of manufacturing costs of numerous commodities. It is hoped that this article will revive discussion on this all-important subject, and that it presages the day when some intelligent use will be made of surplus power.

Cooperative Work on Joint Pole Use

Since both telephone and electric service customers must be reached by the two utilities it is obvious that the joint use of poles would have many advantages to the utilities, the customers, and the community. Important operating problems resulting from such close proximity are receiving joint study; new problems constantly arise with developments in practise. The present status of cooperative study of joint use is outlined here.

By J. C. Martin* and *H. L. Huber

Associate A. I. E. E.

Chicago, Ill.

Member A. I. E. E.
American Tel. & Tel. Company
New York

PRINCIPLES and practises for the use of wood poles jointly by electric supply companies and communication companies as recommended by the Joint General Committee of the National Electric Light Association and the Bell Telephone System under date of February 15, 1926 contemplated that each party to such joint use should:

1. Be the judge of the quality and requirements of its own service, including the character and design of its own facilities, both now and in the future.
2. Determine the character of its own circuits and structures to be placed or continued in joint use; and determine the character of the circuits and structures of others with which it would enter into or continue in joint use.
3. Cooperate with the other party so that in carrying out the foregoing duties proper consideration will be given to the mutual problems which may arise, so that the parties can jointly determine the best engineering solution in situations where the facilities of both are involved.

From the foregoing it may be observed that while each party retains full responsibility for its own problems, emphasis is placed upon the mutual advantages accruing from conscientious effort to find the best over-all engineering solution in each particular situation. These principles are among the important recommendations during a decade of cooperative studies, and they form the basis upon which practically all cooperative work is being carried forward.

It is the purpose of the following paragraphs to describe briefly what has been done by the joint subcommittee on development and research and what is being done in connection with the engineering and economic problems encountered in joint use.

CONSTRUCTION PRACTISES

From the inception of the joint use of structures, joint-use construction practises have undergone almost constant change and improvement and continued development is to be expected for the future. However, many of the fundamental requirements for securing satisfactory conditions on jointly used poles were recognized at an early date and form the basis for present day practise.

In so far as practicable, power wires, because of their relatively greater mechanical strength, have been assigned to the upper positions on jointly used poles. Also, with power wires in the upper position, telephone linemen are not required to climb through power circuits, with the exact nature and characteristics of which they are not always familiar.

Good practise dictates sufficient clearance between levels of power and telephone wires to allow for safe working. Where wires to street lights and underground connections to aerial plant require vertical runs on jointly used poles, their location, insulation, and mechanical protection have received careful study, looking toward the elimination of hazards to workmen. Sufficient clearances between vertically run circuits of one type and the equipment of another utility on the same pole have been found to be most important from the standpoint of avoiding service-interruption to both power and telephone systems. In this connection it is well to note that any situation where insufficient clearance between power and telephone facilities is provided may result in trouble for one or both.

Present day construction standards therefore emphasize the necessity of maintaining proper clearances as well as strength of construction; and experience shows that where these standards have been practised, trouble from these sources has been kept within a reasonable limit. The joint general committee is giving

From "Status of Cooperative Work on Joint Use of Poles," (No. 31-24) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931, as Part IV of a symposium on coordination of power and telephone plant.

careful consideration to the matter of construction standards on jointly used poles. Pending the development of complete specifications covering recommended practises under various conditions, the National Electrical Safety Code is recommended as a guide to practise.

PROTECTIVE DEVICES

Both telephone and electric supply circuits are equipped with protective devices fundamentally the same in pinciple and falling within two general classifications:

1. Those which provide protection from abnormal voltages consisting of protector blocks in the telephone plant and lightning arresters in the electric supply system.
2. Those which provide protection from abnormal currents consisting of heat coils and fuses in the telephone plant and fuses and circuit breakers in the electric supply systems.

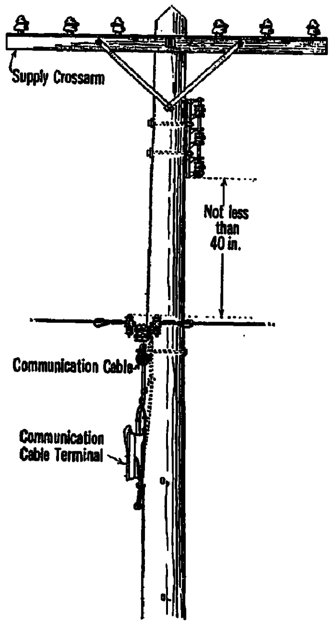

Fig. 1. An example of good practise in joint pole use showing one method of accomplishing satisfactory conditions

These protective devices are of secondary defense against abnormal conditions which it is impracticable to avoid either by design or through adherence to construction standards.

In spite of all practicable precautions with regard to clearances, strength of construction, and insulation, accidental breaks occur both in power and in telephone wires; therefore, and also because of the limitations of protective devices, joint use with certain types of circuits is questionable. Differences of opinion exist between engineers as to the degree of hazard involved in joint use between telephone plant and power circuits of various types, voltages, and connected capacity. This problem has increased in importance as the use of higher distribution voltages and greater generating capacities have been adopted. The joint subcommittee on development and research now is studying several typical rural and suburban areas to determine the over-all advantages and disadvantages of the use of higher distribution voltages and of joint use with these voltages under present conditions.

In connection with these problems the joint committee carried on experimental work to determine the characteristics of various types of fuses. Tests made in a laboratory where 20,000 kv-a. of generating capacity was available showed the range of dependability that could be placed upon the various fuses for interrupting voltages ranging from 2.3 to 13.2 kv. Another phase of experimental work covered breakdowns with direct current and with 60-cycle alternating current, and a complete cathode ray oscillographic study of the behavior of carbon-block protectors and neon and vacuum tubes under steep wave fronts. These tests showed that the carbon-block protector has a breakdown point with all types of applied wave fronts that is sufficiently fast and low to protect the insulation now used in the communication plant. The shortcomings of these blocks lie in their tendency to ground the circuit permanently when forced to carry current for any appreciable length of time. Tests with steep wave fronts were carried to a rate of rise of 36.5 kv. per microsecond.

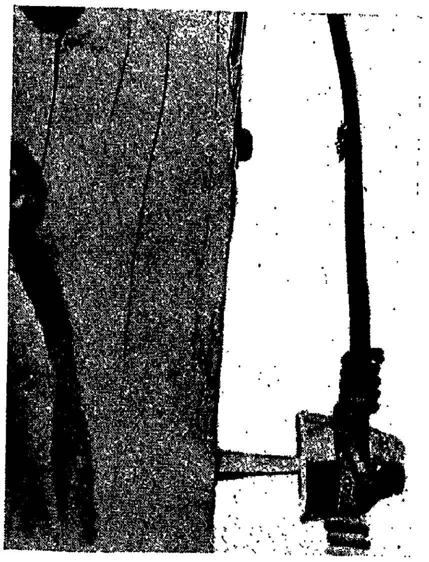

Fig. 2. An example of improper construction. Wire was pulled against through-bolt resulting in an insulation failure which interrupted both services. Wire removed to permit photographing

MUTUAL RESPONSIBILITY FOR PROTECTION

The problem of adequate protection of the telephone plant in joint use obviously cannot be solved by the development of telephone protective devices alone; protective devices in the power system are of equal importance. One problem in present development and research work is the fixing of the part that the protective devices on each system must play in abnormal conditions; the burden of weaknesses in the protective equipment of one system must not be thrown upon the protective equipment of the other. Therefore, the next step in this investigation is a determination of the over-all characteristics of power circuit and telephone circuit protection under typical conditions of contact between the two.

- One of the important functions of the power-system protective devices is that of clearing power-system faults in a reasonable time interval. Obviously, telephone protective equipment cannot be expected to prevent damage to telephone plant in case of contact between the wire circuits of the two utilities when power-system protective devices fail to operate and the physical contact of the circuits is maintained over an indefinite period of time.

All of these problems are being approached upon the basis of determining the best over-all engineering solution to the end that both systems may provide their services in the most convenient and economical manner.

The various operating problems which have arisen almost since the birth of the power and telephone industries, and the investigations conducted by the joint subcommittee on development and research, indicate the importance of giving careful consideration to the inductive coordination features of joint use and of including this factor in studies of the relative advantages and disadvantages of joint use as compared with separate lines. This factor, of course, should be considered from both its technical and economic aspects.

In the inductive coordination of the two distributing systems much can be accomplished by cooperative advance planning. In urban areas where the telephone circuits are largely in cable, there is about a two-to-one ratio in the inductive effects between a joint line and separate lines across the street. In rural areas where the telephone circuits are largely open wire, the ratio of the inductive effects on joint lines as compared with separate lines across the highway is much greater—other things being equal.

In urban areas the power and telephone companies through cooperative planning frequently can arrange to establish important power feeders and telephone circuits on separate streets, thereby avoiding large inductive effects, and permitting more extensive joint use of branch lines. A careful review of the equipment used on the power and telephone circuits and the introduction of operating practises designed to limit the inductive susceptiveness of the telephone circuits and the inductive influence of power circuits, form an important part of advance planning and cooperation.

In the case of rural lines where the telephone circuits are largely in open wire and the exposures between particular circuits are likely to be long, joint use is not always practicable. In these cases locations for separate lines usually are available. Furthermore, joint use in rural areas is not always economical from a purely construction standpoint. Joint use with telephone toll circuits or power transmission lines has not, in general, been found desirable.

Reactance Relay Performance Reviewed

Results of a year's experience with reactance-type distance relays in the South is interpreted as demonstrating the correctness of the reactance principle. Difficulties that have arisen as a result of interconnections which operate near the stability limit, and other operating problems, are outlined here with resulting conclusions.

By E. E. George
Member A. I. E. E.

Tennessee Electric Power Company
Chattanooga

OPERATING EXPERIENCE has shown the correctness of the major principles of design and application of reactance-type distance relays on the system of the Tennessee Electric Power Company. Several difficulties have been encountered, but these have been given less weight than the prime considerations of carrying high loads safely during emergencies and of clearing the majority of faults selectively during all operating conditions.

On February 9, 1930, the company installed three reactance relays at its Great Falls hydro plant. These relays were of the normal-speed distance type (LB-1) furnished by the American Brown Boveri Company, but built in Switzerland by Brown Boveri, Limited. This is believed to be the first installation of reactance relays in this country. Since that time 24 more of the LB-1 relays and 27 General Electric type GAX relays have been installed, making a total of 54 distance relays of

---

From "Operating Experiences with Reactance Type Relays" (N . 30-181), presented at the A. I. E. E. Southern District meeting, Louisville, Ky., Nov. 19-22, 1930.

the reactance type on that system. In addition, six high-speed distance relays of the Westinghouse impedance type (HZ) are now being installed.

In Figs. 1 and 2 are shown typical wiring diagrams for the two types of reactance relays and how the test facilities preferred by the Tennessee company have been applied. If it is desired to use the auxiliary equipment offered by one manufacturer for securing ground protection as well as phase protection, the test scheme becomes more complicated.

Reasons for the rapid installation of these new types of relays may be of general interest; herewith is given a tabulation of the variation in short-circuit kv-a. on the various high-voltage buses of the system. This variation is caused chiefly by changes in operating conditions with steam and hydro generation at widely separated locations. The tabulation covers the total short-circuit kv-a. on the bus; of course, any one outgoing line has substantially less current.

The location of circuit breakers on the 154-kv. and 110-kv. systems, together with the type of phase protection now in service at each are shown in Fig. 3. Many of the line sections are of No. 2/0 copper or its equivalent. The map, together with the table of short-circuit kv-a., shows why the short circuit at the end of a long section may be even lower than the normal load of the line. Furthermore the opening of a section under fault frequently requires the adjacent sections to carry as much as twice normal load for a minute or more. Over-current relays (and relays having over-current pick-up) have proved inadequate and almost useless under these conditions.

TABLE I—VARIATION IN SHORT-CIRCUIT KV-A. ON TENNESSEE ELECTRIC POWER SYSTEM

	Maximum	Minimum
Arlington	680,000	160,000
Centerville	360,000	170,000
Great Falls	480,000	210,000
Hales Bar	600,000	250,000
Ocoee No. 1	780,000	250,000
Ridgedale	560,000	220,000
West Nashville	390,000	180,000
Wilson Dam	800,000	150,000

The principle of the distance relay finds a ready application in handling this situation. Reactance-type relays were preferred over the impedance type since it is thought that the former give a more accurate measurement of the distance to the fault by being independent of arc resistance.

Certain factors relating to the installation and operation of both types of relays have been demonstrated conclusively and are outlined in the following paragraphs.

High-voltage-potential supply is necessary in practically all cases because incorrect operation is likely to result when running on low-voltage supply. After trying various substitutes, the potential transformer has proved the best, and in the long run the most economical source. Pilot indication is highly desirable on potential supply; neon lamps serve this purpose admirably.

By the use of distance relays each section of line is protected independent of other sections and selectively without cascading relay settings.

The amount and location of generating capacity has no appreciable effect on the time of clearing faults. Loads much beyond the sustained thermal capacity of a transmission line can be carried without tripping, but if the voltage is low enough to indicate a fault in the protected zone, a secondary current of about two amperes or more will operate the relay in a predetermined time. Impedance releases or starting units on reactance relays, however, should be set rather high—say at ten amperes or more.

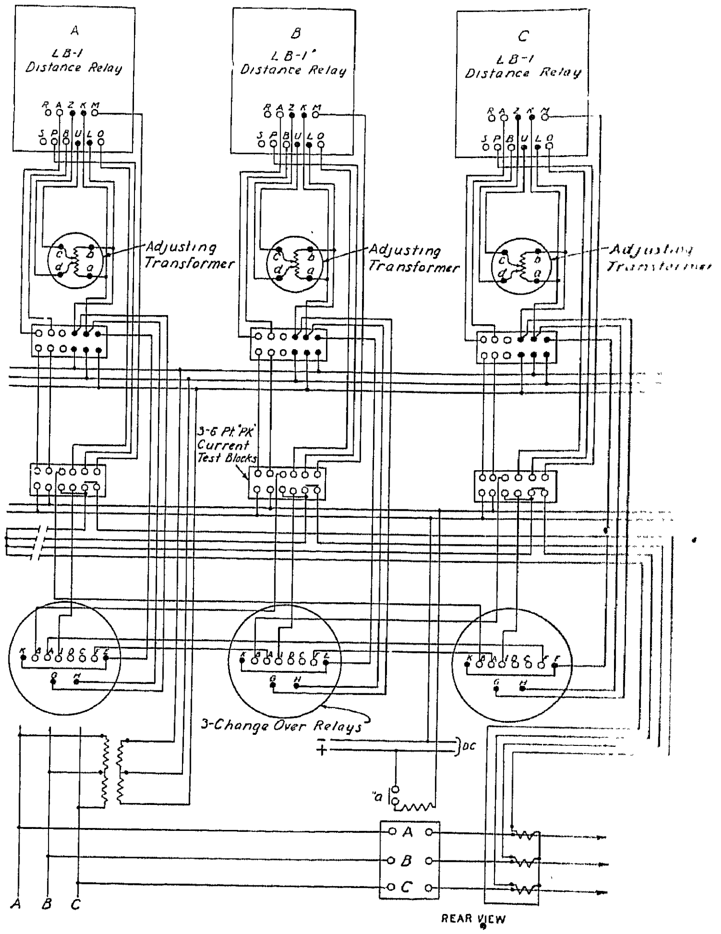

Fig. 1. Wiring diagram for type LB-1 distance relays

Relays of this type can also be used for fast bus protection, but it is not possible to obtain correct directional action in all cases for heavy faults close to the station. It is recommended that the buses of important stations be protected independently so that the distance relays may be used for outgoing protection only.

Both types of reactance relays have been found to operate on arc faults in the same time as on solid short circuits, even up to the longest arcs that could be maintained on the system.

The cost and importance of distance-relay installations justify maintaining complete and accurate operating records, and a careful study of these records after they are obtained. This does not mean, however, that relay settings or schemes should be modified on account of one report of incorrect operation; it is too difficult for the average operator to determine exactly what happens and except in case of careful observation on staged test, too much weight should not be given to any one reported erratic performance.

Quick-trip ammeter installations as used to record neutral-ground current have been very helpful in analyzing relay operations. The absence of a ground-current record indicates a phase-to-phase short circuit which should operate the distance relays. These graphic ammeters frequently show ground current at the same time the distance relays operate, indicating a two-phase-to-ground short circuit, or a phase-relay operation on a single-phase-to-ground fault. Automatic oscillograph installations should also be very valuable in analyzing relay operations especially on occasions when the station operator's time is limited.

In this territory most of the high-voltage phase-relay operations occur in June, July, and August, during the height of the lightning season, thus giving a rather limited time in which to make and note the effect of any changes in relay installations. This means that in order to record the effect of any improvement or revision before the lightning season ends, questionable or incorrect operations must be followed up promptly. The lightning storms are not only concentrated during the summer months, with a peak in July, but these storms also occur most frequently in the afternoon. This extreme concentration of trouble greatly complicates relaying and dispatching problems due to independent troubles occurring close together, or even simultaneously. A second line may relay out before the first line can be closed back in, thus leading to confusion in the operating records as well as to interruptions to customers provided with two or more sources of supply, even though none of the circuits are in trouble permanently.

One type of reactance relay is equipped with a distance indicator which has been very helpful in studying the conditions under which the impedance release operated. It would also be desirable to have more than one target on the step-by-step distance relays so that there would be a record of whether the relay tripped on instantaneous, intermediate, or back-up time. It has been found impracticable to determine this by watching the relay, even on staged tests.

For distance relays, no entirely satisfactory method of low-voltage routine tests has been devised but they have been checked by staged tests during installation and in case of questionable operation, occasionally thereafter.

In addition to the foregoing conclusions regarding distance-relay performance there are certain questions which in the opinion of the writer have not been definitely answered as yet. These together with some of the evidence that may be helpful in reaching conclusions, especially when and if corroborated by further experience, are outlined in the following paragraphs:

Table II is a condensed summary of the operation of distance relays on this system from the dates of their installation up to the present time. Details of these operations are tabulated in the complete paper.

Apparently the operation of all types of these relays is highly satisfactory on radial feeders. The only difficulties arise on trunk lines and on interconnections where wide variations in power factor during load swings seems to be one of the chief difficulties.

The performance of distance relays under out-of-step conditions is still uncertain; this liability, however, is not confined to these relays, as it is definitely known that the old impedance relay will operate quickly on any out-of-step condition if the current peaks exceed the pick-up value for a short time. Many interconnections are subject to more or less prolonged surging somewhat below the stability limit and relays should hold in all such surges. This is one of the problems on the East Tennessee interconnection.

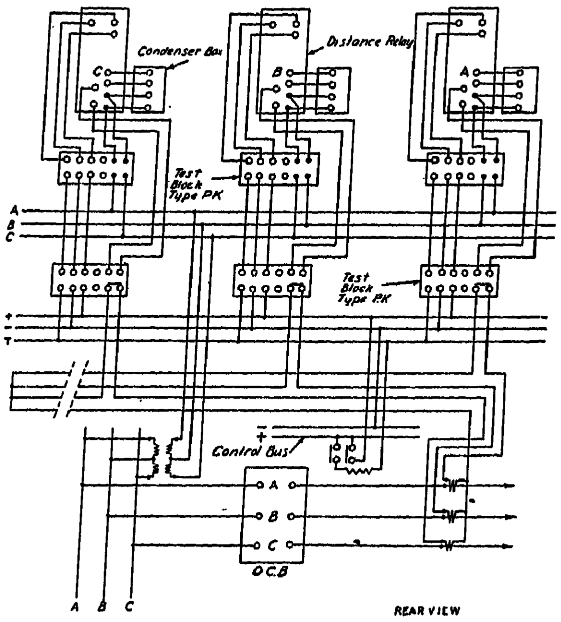

Fig. 2. Wiring diagram for type GAX distance relays

Unfortunately, however, there is no precedent for saying that a line should or should not relay on out-of-step conditions. As a result of relay subcommittee investigation, it has been suggested though tentatively that severe out-of-step conditions should cause relay operation, but only at one location which should be at the point of maximum voltage variation.

Operating experiences also show that impedance releases or starting units should have reset values fairly close to the release values, particularly if the starting unit is non-directional. Otherwise a fault may be cleared promptly at some other location, but the resulting surging or readjustment of power flow may be sufficient to hold the relay released and cause incorrect operation.

TABLE II—SUMMARY OF REACTANCE-RELAY OPERATIONS

Correct operations	47
Questionable operations	7
Wrong operations	0
Inadequate potential supply	18
Total	72
Analysis:	
Correct operations	
Line relayed at one end only	3
Same line relayed simultaneously at other points	28
Line relayed while being supplied from one end only	5
Back-up protection	3
Low-voltage bus failure	1
Bad synchronizing	5
Bus protection	2
Total	47
Questionable operations	
Out-of-step conditions	7
Total	7
Inadequate potential supply	
Cross-phased	3
44-kv. trouble	5
Bushing potential devices	5
110-volt secondary trouble	5
Total	18

In this connection it would be advantageous for the starting units to be made more readily adjustable. At present they are designed and factory-adjusted so as to give back-up protection to only two or three average sections of line, while the distance measuring element is flexible and can be adjusted for almost any combination of sections. The time setting on intermediate and back-up operation of step-by-step distance relays should be rather long—probably 60 cycles or more for the intermediate time if used on heavy interconnections. This is a tentative conclusion from operating experience on the East Tennessee interconnection.

The instantaneous element on a distance relay may operate too quickly if the relay trips under two or three cycles, since incorrect operation may occur due to breaker adjustment. A certain definite time is required for proper directional discrimination, and it does not seem to be wise to try to speed up the initial time too much on certain types of relays.

Distance relays can be used successfully on the same system with other types of relays, but if the ordinary types of relays operate slowly under minimum generating conditions, the distance relays will operate frequently ahead of them. It is entirely feasible however to use separate and independent ground protection with these relays. For ground protection it has always been the practise of this company to use current directional ground relays and no change was made in this practise when distance relays were installed for phase protection; however, both manufacturers have developed schemes of ground protection using distance relays and star potential supply.

Electrical Porcelain

Simple comparative tests of American and European samples of standard insulating porcelains reveal strikingly similar characteristics in the finished products in spite of variations in raw materials and manufacturing processes.

By H. M. Kraner

Westinghouse Electric & Manufacturing Company
East Pittsburgh, Pa.

ALTHOUGH the investment in the insulators used on a modern transmission line represents only a very small percentage of the total cost of the line, much depends upon their continuous and satisfactory performance as an electrical insulator and a mechanical support.

While the electrical industry was still young, the ceramic industry was operating on rule-of-thumb methods. As a result, it was difficult for the electrical engineer to know anything more about porcelain than that the product of one manufacturer was satisfactory whereas that of another gave trouble under the various new conditions which were being encountered. Recent advances in silicate chemistry, made possible by the use of the petrographic microscope, and the application of fundamental mechanical tests to these materials, has done much, however, to diminish this handicap. As a result, manufacturing methods have been improved greatly, and porcelains of much better quality and greater uniformity now are being produced.

Nearly all the many kinds of porcelain now used for transmission line service are made essentially of clays, flint (quartz) and feldspar. Obviously porcelains having all kinds of properties might be made by varying the proportions of these constituents; by good and bad methods of mixing and forming, and by firing at various rates and for various lengths of time.

The clays are used for their unique plasticity which makes possible the molding and drying of the pieces. Flint (quartz) is a somewhat inert refractory material which during firing adds viscosity to the mass and also acts as a skeleton for the entire mass at that time. Feldspar is a melting constituent which, when fused, carries the clay and some of the quartz into solution in the resulting glass matrix. Thus the clays are all-important in the forming operation, while the feldspar is particularly important in the firing process.

Unlike many manufactured products in which the final operation before assembly brings the piece to the prescribed dimension, porcelain undergoes the firing process with a 12 per cent shrinkage after the final dimensioning operation. Any irregularity in the manner in which the piece is placed or fired may affect its ultimate dimensional accuracy and hence the firing as well as the composition is extremely important.

European practise is to fire to approximately 1,400 deg. cent. whereas only 1,200 deg. cent. with a longer firing time is customary in America. Analyses show, however, that the chemical composition of these porcelains is very similar.

European contemporaries have conducted much more fundamental testing on various ceramic materials than has been done in this country. American tests have been limited to those properties which are directly applicable to, and of value in, the finished products—tensile strength, compressive strength, cross-bending strength, impact and dielectric strength. Of these the cross-bending test seems to be most suitable for fundamental indication of the merit of a porcelain. Small inaccuracies in the test piece do not greatly affect the results obtained, and the variation in diameter does not affect the modulus of rupture of a given material as in the case of tensile testing. It has been found also that this method of testing can be used to good advantage as a control procedure in the factory.

Results of a series of cross-bending tests made on various types of porcelain with the machine shown in the accompanying illustrations are given in Table I. As may be noted, the strain cable on the testing machine applies load to the center of the test bar in such a way that the distribution of stress across the diameter of the bar is uniform. Round test pieces ⅜ in. in diameter and 3 in. long were used.

As Table I shows, the resistance of the material to heat shock also was determined. This was done by heating the small test pieces to the temperatures indicated, and quenching them in water at room temperature. The change in strength after such treatment is an indication of the value of the material's resistance to heat shock regardless of the method of manufacture. It is interesting to note that the modulus of rupture for the various samples of American porcelain tested gave a maximum deviation of only three per cent from the average. These results clearly demonstrate also that the improvement in properties resulting from firing at temperature much higher than encountered in American practise is not so great as might be expected, nor at all commensurate with the higher firing cost involved.

High-strength compositions for somewhat stronger insulators are possible, however. In this connection it must be remembered that the economics of the situation keep the industry within fairly narrow limits. The increase in cost attributable to the use of more expensive materials is relatively slight; the real expense comes in the fuel used to obtain the higher firing temperatures required for such compositions; which at

---

Front view of porcelain tester showing test sample in place and method of obtaining evenly distributed strain

present is about 40 per cent of the total manufacturing cost.

It may be noted from Table I that several materials show greater strength unglazed than glazed. This indicates that these glazes have a coefficient of expansion widely different from that of the body and place the two under differential stress. A properly fitting glaze should increase the mechanical strength of the porcelain by sealing the exposed contacts between the grains of the structure.

TABLE I—MODULUS OF RUPTURE OF CERAMIC MATERIALS, INCLUDING TESTS ON QUENCHED SAMPLES

	Lb. per sq. inch			
		Quenched from		
	Not quenched	200 deg. cent.	300 deg. cent.	400 deg. cent.

German Porcelain C				
Glazed	10,797	5,012	3,730	3,571
Unglazed	12,786	10,465	4,291	3,853
Steatite (plastic process)				
Glazed	20,086	14,550	All shattered	
Unglazed	15,667	7,266	5,720	4,166
Melalith				
Glazed	11,236	All shattered		
Unglazed	14,810	5,204	4,311	3,327
Sillimanit				
Glazed	12,926	13,231	3,510	3,125
Unglazed	11,135	4,480	3,382	3,440
American Chemical Stoneware				
Glazed	8,922	7,670	3,390	2,920
Unglazed	7,980	6,013	3,305	2,655

In some cases the glaze is detrimental to resistance of thermal shock; for upon quenching, it not only weakens, but shatters badly. The question of glaze fit has been studied from various angles and its importance has been demonstrated in many different ways.

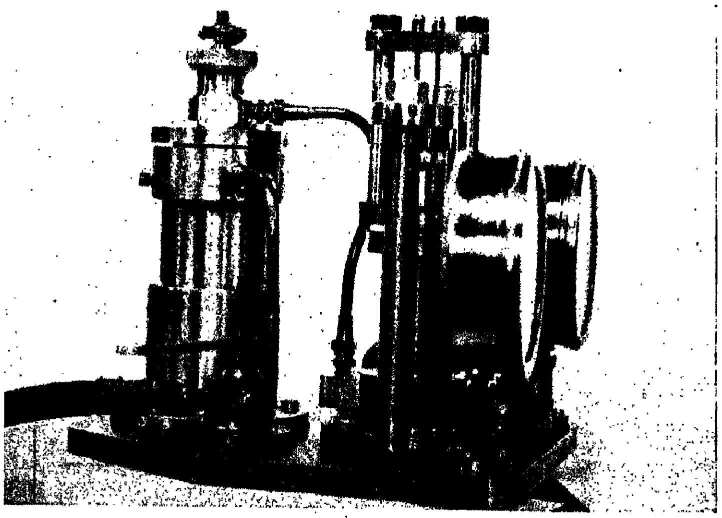
In regard to the uniformity of composition of porcelain now being manufactured, it is sufficient to say that recent chemical analyses reveal only slight differences in these compositions. The best of them is not the highest in silica content, nor the lowest in alkali content (therefore lowest in feldspar); and it has only an average clay content as judged from the alumina present.

The manufacturer of porcelain undoubtedly will find that he can make the greatest strides towards producing a reliable product by keeping his processes as simple as possible and by developing rational methods of control for them. This, unfortunately has not been done extensively, but a striving for uniformity in this manner is undoubtedly of greater benefit to the industry than the use of peculiar processes of unproved or questionable scientific value.

Checking raw materials, fineness of grinding within the plant, consistencies, forming and drying operations and particularly firing processes should be under close control and observation at all times. A full understanding of the effects of varying cooling rates at the various stages of the cooling cycle is also necessary for the most effective operation.

For a long time the x-ray has been looked upon rather hopefully as a possible means of accomplishing routine inspection of porcelain for flaws. But unfortunately the length of time required for an exposure prevents it being used as anything but a laboratory tool.

The assembly of the fired porcelain into pin-type or suspension insulators is as important, or perhaps even more important, than the production of the porcelain



Side view of porcelain tester

itself, for with faulty design or assembly, the best insulating medium may give only inferior mechanical strength and insulating value.

Cement used in the assembly of the insulators must be controlled for uniformity as closely as the clays used in making the porcelain. Temperature variations affect the viscosity and resulting thickness of plastic coatings applied to sand bands and other parts incorporated in the assemblies.

Within the last few years the design of the various parts of these assemblies has been studied systematically from purely theoretical, mechanical, and mathematical standpoints. Photoelastic studies by which accurate determination of stress concentrations in these assemblies have been made have assisted materially in determining the best types of design. The use of other methods of stress studies in three-dimensional models has now been developed. These studies have paved the way for a distinct advance in insulator design, the benefits of which have already been made apparent.

Hydrogen Cooling for Turbine-Generators

With the development of efficient sealing glands and reliable control apparatus the already proved advantages of hydrogen gas as a cooling medium for rotating electrical machinery appear to be readily available for large generators. Actual operating experiences with a 7,500-kv-a. unit are outlined here.

By M. D. Ross
Associate A. I. E. E.
Westinghouse Electric & Manufacturing Company
East Pittsburgh, Pa.

LARGE TURBINE-GENERATORS of today are appreciably smaller, more reliable, and more efficient than the corresponding machine of even five years ago. These improvements are traceable largely to such factors as better methods of ventilation, stronger rotor steels, lower loss in armature laminations, and improved methods of insulating rotor windings. However, in recent designs for the larger machines using present materials, methods of construction, and accepted performance characteristics, there are indications of a close approach to the limits of possible ratings. Therefore, it is believed that any marked further advancement in performance or maximum size probably will result only from radical changes in fundamental design.

Consequently, a great deal of research has been carried out recently in connection with the cooling of rotating machinery by means of gases other than air. A survey of available gases shows that because of its low density (about 7 per cent that of air) and high heat-transfer characteristics with forced convention, hydrogen is the gas most suitable for this purpose. Furthermore, since windage losses vary approximately in proportion to the density of the cooling medium, such losses through the use of hydrogen can be reduced to a negligible figure. Some of the advantages of hydrogen as a cooling medium for rotating electrical machinery are summarized briefly:

1. Windage losses, which may be as much as 40 or 45 per cent of the total losses, are reduced to about 10 per cent of their value in air.
2. For a given amount of active material the rating of a generator with hydrogen cooling would be about 25 per cent greater.
3. In an atmosphere of hydrogen corona has little, if any, effect on insulation. Insulation operating in hydrogen therefore should have a much longer life than in air.
4. Because of the absence of oxygen, fires in th generator cannot occur.
5. Smaller gas coolers and less cooling water are required than with air cooling.

SHAFT SEALS FOR TURBINE GENERATORS

One of the most important developments in connection with hydrogen cooling for turbine-generators has been the design of sealing glands to prevent gas leakage around the shafts where it emerges from the gas-tight enclosure. Experimental work started in 1925 and which covered various methods revealed that a liquid seal employing oil as the sealing medium was best adapted for use with the relatively high shaft speeds involved. Data showed also that a suitable supply of oil under pressure could be obtained from the turbine lubrication system.

An experimental sealing gland was built in 1926 to determine the performance that could be expected in seals for large generators; details of this gland are shown in section, in Fig. 1. Oil under pressure is fed into a groove in the center of the seal and flows both ways over the shaft; the oil film thus formed between the shaft and the seal casting is sufficient to stop the flow of gas at that point provided the oil pressure is higher than the pressure of the gas in the machine. The flow of oil is throttled to a minimum by three

small brass rings fitted closely into grooves in the seal casting and held lightly against the shaft by coil springs.

Tests made on this gland showed that the loss of hydrogen through the seal was very small and that no special detraining tanks were required to separate the hydrogen from the oil before returning the oil to the main system. It was found however that a certain amount of air was being carried into the gas enclosure by the gland oil. Therefore from time to time a quantity of hydrogen gas would have to be added to the mixture to maintain a suitable purity within the machine. Tests showed that for the largest machines this quantity should not exceed 200 cu. ft. per day.

EXPERIMENTAL TURBINE GENERATORS BUILT

In 1928 a 7,500-kv-a., 3,600-rev. per min. generator designed for hydrogen cooling and incorporating the sealing gland just described was built and tested. The frame was constructed along standard lines with certain modifications to make it gas tight. Tests on this machine indicated that in order to obtain minimum gas leakage, frame structures for hydrogen cooling would have to be quite different from the air-cooled designs.

Accordingly early in 1930 a second machine of the same capacity and speed was built and put on test (see Fig. 2). The generator frame was fabricated from steel plate with a minimum length of bolted joints. Active parts of the generator were the same as the standard air-cooled machine parts, and no particular effort was made to design the machine to obtain maximum results with hydrogen cooling. Two sealing glands of the type described were provided, rigidly attached to the bearings, and connected to the end-bells by flexible diaphragms.

Two Griscom-Russell finned-tube gas coolers were built into the generator frame *above* the armature core. To simplify construction and to make the cooler sections more accessible for cleaning straight-tube coolers were adopted and since experience with coolers on a large number of machines never had indicated trouble from leakage or fractured tubes no operating hazards were considered involved in placement of the coolers above the generators.

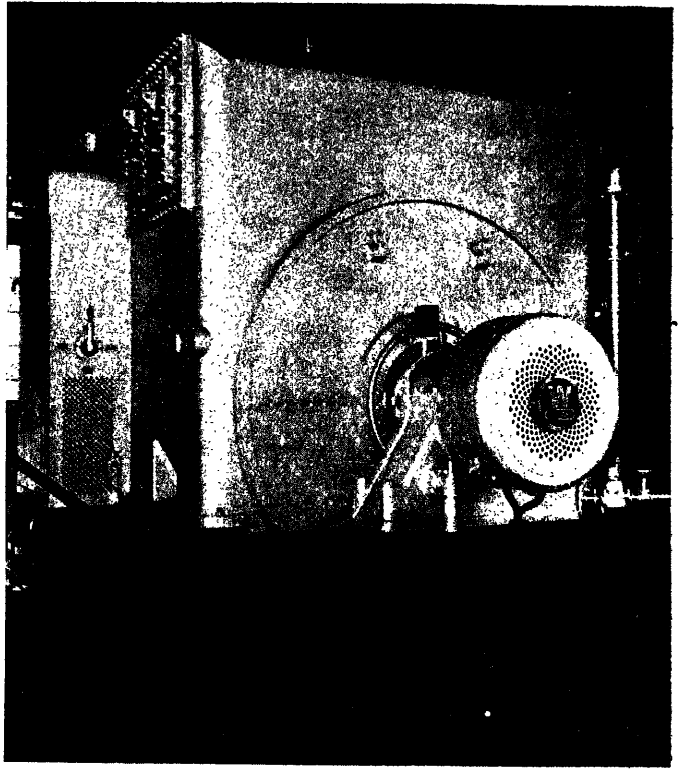

Fig. 2. A 7,500-kv-a. generator with frame and housing designed for hydrogen cooling. Fin-type coolers may be noted above the rotor; control cabinet at the left

Armature leads were brought out through six gas-tight condensers bushings in a flange on the bottom of the generator. Through holes drilled in the shaft field leads were carried to a point outside the bearing where they were connected to the collector rings. Insulating stuffing nuts were provided to keep the gas from leaking around the field leads.

A special system for controlling the gas in the machine was developed, as simple and sturdy in design as possible so that its operation would be readily understood by the average station attendant. In Fig. 2 the control panel is shown bolted to the side of the generator. Principal functions of this apparatus include:

1. Maintenance of gas pressure in the machine at somewhat above atmospheric, to avoid leakage of air into the machine.
2. Warning to the operator when the purity of the gas is too low, so that more hydrogen may be added to bring it up to the proper value.

Electrically-operated intake and relief valves controlled by pressure-operated switches maintained the pressure in the machine at the proper level. A small motor-driven fan running at constant speed drew a small quantity of gas from the generator and before returning it to the machine forced it through an orifice. The pressure difference between the two sides of the orifice is proportional to the density of the gas passing through it. This difference in pressure was registered on a gage mounted on the front of the panel, so that the operator could readily determine the purity of the gas in the machine. Under normal operating conditions, the purity of hydrogen in the machine was maintained at a value greater than 95 per cent which, considering that mixtures of air and hydrogen containing more than 70 per cent hydrogen are non-explosive, allowed a wide factor of safety.

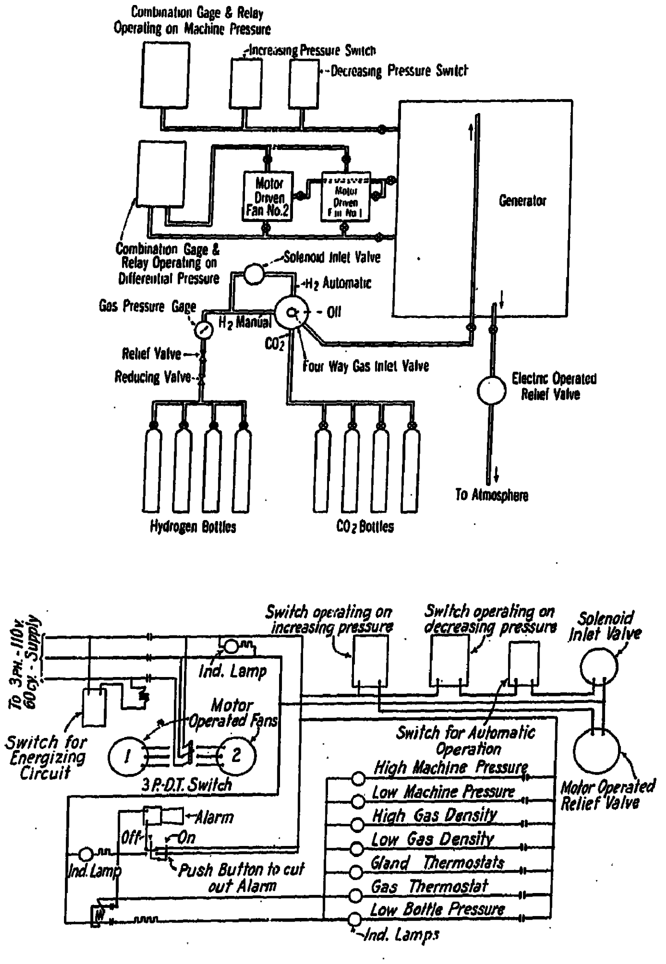

Fig. 3. Piping and wiring diagrams showing hydrogen handling and control methods

Piping required for the gas system is shown schematically in Fig. 3. Fig. 4 shows the wiring diagram for the electrical apparatus used to operate the gas control system. As may be noted, alarms are provided to warn the operator in case of any troubles in the gas system. A supply of carbon dioxide gas is provided with suitable control valves, to take care of removing the air when filling the generator with hydrogen or to remove the hydrogen when scavenging the machine so that explosive mixtures will not be obtained.

EXPERIMENTAL OPERATING DATA

Up to the time of writing this paper the generator now under test has been operating satisfactorily for seven months. No troubles were encountered with the control and sealing gland features and the glands themselves showed no evidence of wear when inspected after intermittent running with no special attention. Whenever the generator was shut down with hydrogen in it the oil pump was kept in operation to maintain the seal at the shafts. Without oil pressure there was some leakage of gas through the sealing glands, but the infiltration of air probably would be very slow.

Comparative temperature rises of the stator and rotor of this generator with air and with hydrogen cooling are given in Fig. 4. With hydrogen cooling, the machine could be rated at 9,375 kv-a., 0.8 power factor. The windage loss with hydrogen was 7 kw. as against 73 kw. with air. This represents an improvement in efficiency of 1.1 per cent at a 6,000-kw., 0.8-power-factor load. The cooling water required for 9,375 kv-a., 0.8 power factor with hydrogen cooling was approximately 40 gal per min., as compared to 80 gal. per min. with air cooling and only a 7,500-kv-a., 0.8-power-factor load.

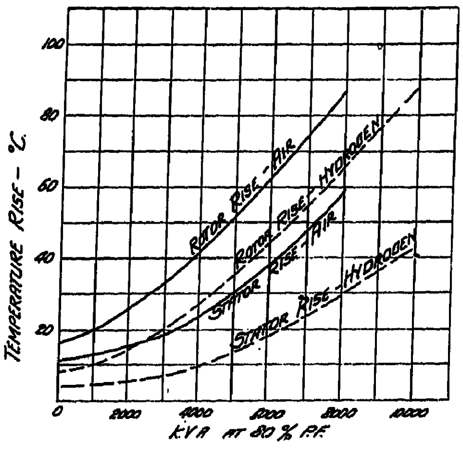

Fig. 4. Operating characteristics of a 7,500-kv-a. machine operating in air and in hydrogen

Desirability of Adopting Hydrogen Cooling

The first question usually raised in connection with hydrogen cooling is: what will happen in case of an explosion? With the worst mixture of air and hydrogen, the explosion pressure will be from 50 to 75 lb. per sq. in., depending upon the size and shape of the gas chambers in the generator. If the frame is provided with a number of diaphrams which will blow out at relatively low pressures, the pressures developed will be lower than the foregoing values. Operating hazards with a hydrogen-cooled generator on a control system such as that just described probably is no greater than those involved in operating other types of station control equipment; therefore it is questionable as to whether frame structures for hydrogen-cooled generators need be made explosion-proof. No attempt was made to design the two 7,500-kv-a. generators described in this article to withstand explosion pressures; however, if an explosion-proof frame be considered necessary it could be built with some increase in cost over that of the lighter frame designed on the basis of gas tightness only.

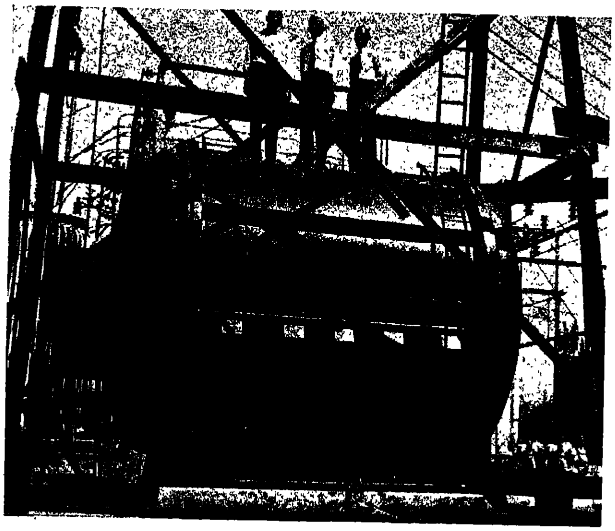

Fig. 5. A 15,000-kv-a., 750-rev. per min., 50-cycle, hydrogen-cooled, synchronous condenser being installed by the Southern California Edison Company, Ltd.

Several hydrogen-cooled synchronous condensers are now in service and as indicated by the number of this type of machine now on order are growing in popularity. As the synchronous condenser does not have to be mechanically coupled with any other apparatus, it can be enclosed readily in a gas-tight casing with provision for cooling the hydrogen gas and recirculating it. The problem so far as hydrogen-cooled turbine-generators are concerned is somewhat different as in order to couple it to the turbine the generator shaft must be brought out through the gas-tight enclosure. It is desirable also to bring the collector-end shaft outside the enclosure to permit work on the brushes while the machine is in operation. This is an important feature in turbine-generators which are sometimes run six months or more at a time without shut-down. However, with the development of sealing glands and control apparatus to the point where their operation can be relied upon in continuous service, there is no apparent reason why hydrogen cooling should not be adopted for large turbine-generators.

Preliminary studies indicate that hydrogen cooling would be desirable in ratings of from 30,000 kw. up. In comparison with the cost of the generator, additional cost of gas-tight enclosures and the control equipment would be relatively small, and the saving in losses would justify the slight additional complication due to this method of cooling. The cost of hydrogen gas should not exceed two dollars per day for the largest generators—a negligible figure when compared to savings in generator losses. As the turbine floor attendant can take care of the gas control equipment the labor cost for operating the generator would be no greater than for an air-cooled generator and while the hydrogen-cooled design would be somewhat harder to take apart than an air-cooled design, the absence of dirt and corona effects in the machine would probably more than balance that point in estimating the cost of maintenance. With built-in gas coolers, as in the hydrogen-cooled machine, considerable space under the generator would be available for removal of condenser tubes and for auxiliary apparatus which is not available with air coolers located below the generator.

The following example indicates the savings in operating expenses with hydrogen cooling, and the possible capitalization of these savings:

Assume:

1. A generator of 100,000-kw. rating, at 1,800 rev. per min.
2. Reduction in windage losses with hydrogen cooling to be 600 kw.
3. Operating time per year to be 7,000 hr.
4. Value of power at the bus to be 0.4 cent per kw-hr.

Savings can be evaluated as follows:

Value of power at bus (4,200,000 kw-hr.).....	$ 16,800
Less cost of gas at $2 per day and cost of hydrogen and carbon dioxide for three fillings after shut-down...............	1,100
Net saving per year with hydrogen cooling...	$ 15,700
Capitalization of savings at 15 per cent......	$105,000

While the first machines built will cost probably somewhat more than the equivalent air-cooled machines, it is hoped that eventually the hydrogen-cooled design will be produced for the same cost per kv-a. as the air-cooled design.

President Lee *answers* Governor Pinchot

AS A MATTER OF RECORD the full text of a telegram received at Institute headquarters from Governor Gifford Pinchot of Pennsylvania and the full text of President Lee's reply thereto are set forth herewith.

GOVERNOR PINCHOT'S TELEGRAM

January 28, 1931

My dear Mr. Lee:

The Annual Meeting of the American Institute of Electrical Engineers now in session is the occasion for my bringing to your attention a matter of grave social import which seemingly calls for action by an association of engineers specializing in the electrical field. The American system of regulation of the electrical industry by state commissions is threatened. The failure of our commissions adequately to control electric service furnished to the homes and stores, and farms, of the country, has occasioned widespread public discontent.

While these consumer groups use not more than one-quarter of the electricity generated they supply approximately sixty per cent of the industry's revenues—and that the most stable portion, as experience in the present depression demonstrates.

One of the principal difficulties in regulating domestic, commercial, and rural electric service is the entire absence of any literature on distribution engineering—a phase of expense peculiar to the service to small consumers and alleged to account for our high domestic, commercial, and rural rates.

Our public service commissions have at their disposal a wealth of information about the generation of electricity and about its transmission. But about distribution, which covers the ultimate disposition of transmitted current to our homes, stores, and farms, there is not a word. The subject has never been discussed before any engineering society—local or national. The secretary of your Institute is authority for the statement that the proceedings of your own organization do not mention distribution.*

Over twenty billion kilowatt hours of electricity were sold to these three classes of small consumers—homes, stores, and farms—in 1929 at an average rate of over $6\frac{1}{2}$ cents per kw-hr. Subtracting an ample allowance for the generation and transmission of the current it will be seen that revenues from this distribution amounts to upwards of $900,000,000 annually out of the industry's total receipts of about $2,000,000,000.

It is most unfortunate that this vast field of engineering and social outlay remains uncovered by an appropriate literature. It would be of material assistance to those of us who are charged by the people with the responsibility for effective and confidence inspiring regulation to have the cooperation of your organization in providing us with the results of technical discussion of distribution engineering, including distribution costs. With the importance and social significance of the matter brought to your attention, I shall hope to see a start made on a literature of distribution comparable to those of generation and transmission.

Yours very sincerely
Signed GIFFORD PINCHOT

PRESIDENT LEE'S LETTER

February 7, 1931

My dear Governor:

Replying to your night letter of the 28th ultimo and with further reference to my acknowledgment of February 3: Your message claims the entire absence of any literature on distribution engineering and also states that our public service commissions have at their disposal a wealth of information about the generation and transmission of electricity, but about distribution, not a word.

For years past, the American Institute of Electrical Engineers has had an active committee on power transmission and distribution, this being one of the standing technical committees of our organization. A large number of papers and discussions upon distribution engineering has been presented at meetings of the Institute and these have been published in our monthly Journal and quarterly Transactions, and are available to the public.

In Pennsylvania, as in most other States, every electric public utility company is required to report in considerable detail on its plant and operations, including for its distribution system its costs under the following headings:

Land
Leaseholds
Rights-of-way
Distribution system structures
Poles and fixtures
Overhead conductors
Overhead transformers
Overhead transformer installations
Overhead services
Underground conduits
Underground conductors
Underground transformers
Underground transformer installations
Underground services
Meters and meter installations

Therefore, after considering your telegram, I fear that you have been misinformed on this particular subject.

The technical problems of distribution are constantly under discussion by our organization and this will naturally continue. These problems involve such references to costs as may be appropriate to an understanding of the engineering aspects of particular problems, but such discussions do not deal with overall costs of service, whether they relate to electric power, telephone, telegraph, railway, or other utilities. Costs of distribution necessarily include taxes, cost of financing, and many commercial and other aspects, often greatly influenced by local conditions, which fall essentially outside the engineering field; hence, discussions of such costs belong more properly to the activities of other organizations.

Our Institute is a professional engineering society, the objects of which, as defined in our constitution, are "the advancement of the theory and practise of electrical engineering and of the allied arts and sciences and the maintenance of a high professional standing among its members."

One of the principal methods of attaining these objects is by holding national, district, and local meetings for the presentation and discussion of electrical engineering and related subjects. Any member may submit for presentation and publication a paper upon any subject within the field of electrical engineering. The code of our technical program committee provides that "to be acceptable a paper should present information which adds definitely to the theoretical or practical knowledge of electrical engineering," and this code also specifies certain groups of subjects which are not regarded as suitable for Institute presentation, including the following: "As abstract propositions not directly connected with electrical engineering,—purely economic and allied studies such as rate making, project financing, obsolescence, depreciation, statistical methods, utility regulation, factory organization, etc."

Respectfully yours,
Signed W. S. LEE

---

*Editor's Note: Apparently this statement represents a misinterpretation of a reply by the editor of ELECTRICAL ENGINEERING to an inquiry from Mr. Morris L. Cooke of Philadelphia, relating *exclusively* to distribution *costs*. It is a matter of record that more than a dozen papers dealing with various phases of distribution engineering have been published by the Institute within the past two years.

Winter Convention's Ten Technical Sessions Each Reported Here Under Separate Heading

Edison Medal Presented to Dr. Conrad

PRESENTATION of the 1930 Edison Medal, highest award of the American Institute of Electrical Engineers, was made Wednesday evening, January 28, 1931, at a special meeting held in connection with the Institute's winter convention, to Dr. Frank Conrad of Pittsburgh, for his contributions to radio broadcasting and short-wave radio transmission. Dr. Dugald C. Jackson, past-president of the Institute, chairman of the Edison Medal Committee, and one of those who assisted in the founding of the award in 1904, briefly sketched the origin and history of the medal. The medal presentation was made by W. S. Lee, president of the Institute, following an inspirational address by Professor Charles F. Scott, past-president of the Institute, and Edison medalist in 1929. An abridgment of Dr. Scott's address follows:

Address of Dr. Chas. F. Scott

"This twentieth award of the Edison Medal is unique, in that the man so honored left school when he was but sixteen—a year before he might have entered high school—whereas all prior recipients of the Edison Medal have attended an institution of higher learning. On leaving school Frank Conrad got a job running a drill press making parts for Shallenberger ampere-hour meters; now, after forty years, this self-made scientist and engineer receives the distinguished service medal of his profession for his important contributions to its advancement.

"Just what differentiated this particular operator of an ordinary machine tool from scores of others in the same shop? What enabled this grade-school lad to meet successfully the competition of thousands of engineering graduates? And this in an age assailed by critics as reducing men to dull automatons! Many of his achievements have determined the course of electrical practise today; untold numbers of them have had an important influence. In the vernacular, this man has pulled himself up by his own boot straps. But what manner of man is this who although little-known to the public has made such a record? And what kind of straps, and what kind of a pull? To answer these questions it is necessary only to trace the man's life and work.

CONRAD'S EARLY LIFE

"What were the antecedents of the . . . boy, useful, ingenious, ambitious? Conrad's father was a railroad man,—a mechanic, a millwright having to do with upkeep and repair of machinery, steam engines and pumps, heating plant, lighting, batteries for telephone, and signals. He had sound ideas about developing boys for he saw to it that Conrad had something to do when not at school by providing him with simple tools and a place to use them—equipment . . . augmented by contributions from the scrap heap of the repair shop.

Facsimile of the face of the Edison Medal, highest A.I.E.E. award, made annually "for meritorious achievement in electrical science, electrical engineering, or the allied arts"

"Conrad learned the door-bell circuit; the ways of connecting battery cells together; he experimented with coils and improvised parts. He was curious about measuring electricity and made his own galvanometers. His mother's father was a civil engineer; Conrad quietly requisitioned his compass, wound a coil to complete a tangent galvanometer and had the satisfaction of a uniformly divided scale.

"Conrad's mother died when he was quite young and he lived sometimes with his father in Pittsburgh, attending the Starrett School, and at other times with his grandparents who lived in Altoona and had a nearby farm . . . But school was perfunctory. Lessons came easily, but the things taught did not excite interest or stimulate investigation and thought. School seemed a waste of time; he wanted to make a steam engine to run his toys or a galvanometer to measure his current. And so the boy brought with him to the laboratory a simple faith in nature's methods which the formal text book did not give . . .

"As co-worker . . . I have known Frank Conrad for many years . . . We met frequently during the twenty years we were together . . . in the same works; . . . in the subsequent twenty years . . . our long-time friendship has deepened . . . Accounts of his boyhood traits, of his development and methods, and of his engineering achievements, are not independent chapters but are interrelated in a single, progressive story.

CONSTRUCTIVE INQUISITIVENESS

"Soon after Conrad began work on the drill press a significant incident occurred; he observed others who were working on arc lamps; he realized their difficulties and devised improvements. These are important steps—observation, analysis, invention . . . Subsequently he found out by trial why volts should not be measured with an ammeter. He made the personal acquaintance of choke coils, transformers, and condensers, and tried about everything he could think of with circuits and apparatus . . . Also he was engaged in studying algebra and geometry by himself . . .

. . . "H. P. Davis and Conrad worked together on the arc lamp, trying to induce it to give a reasonable performance on alternating circuits. The early induction-indicating instruments and watthour meter were large and expensive and although these lay outside of their official province, they undertook to study them as a sort of extra-curriculum activity. They developed a simple form of long-scale indicating instrument which is still used.

"Conrad then sought improvement of the watthour meter and . . . by a happy combination of painstaking study and intelligent cut-and-try . . . he evolved in 1897 the type of magnetic circuit which still is used in the "round-type" watthour meter.

Typical Radio Amateur

"The radio story is fascinating; it began in a simple, indirect way about 1914. A fellow engineer boasted a high-grade watch; . . . . in lunch-table discussion Conrad entered his mongrel timepiece in competition. Realizing that his watch would make a better showing if reset nightly by Arlington time signals he undertook to make a radio receiver, and presently had a crystal device by which he heard ticks. Uncertain whether it was Arlington, he improved his receiver, learned the Morse code, and found the ticks were the station call of a nearby amateur. Presently the Arlington signals made his watch the winner.

"Radio interest continued. His company took part in war activities and he was assigned radio problems and was in consulation in Washington, D. C. Among other achievements was a 1,000-cycle, 200-volt self-exciting generator for airplanes, weighing eleven pounds (much less than the French equivalent), encased with the radio equipment, and driven by a propeller. This was unique in being an American radio device which saw actual war service.

"Following the war, . . . Conrad had an experimental station at his home. One problem was to perfect apparatus for communication between the company's factories in different states. In these local tests his conversations and phonograph music were heard by neighboring amateurs; they liked music better than Morse code; they found the source and asked for more . . . The enterprise grew . . . Presently the studio was moved from garage to house and there were musical groups who were the original radio artists—predecessors of Damrosch and Amos 'n Andy . . . From neighborhood broadcasting came national broadcasting.

Genius

"Genius sometimes consists in selecting the thing which though simple is worth while. Among the innumerable wireless amateurs there was one who produced something different; one who attracted and interested others, and at some personal inconvenience contributed to their satisfaction and enjoyment . . . By painstaking observation and investigation in a discarded field Conrad discovered the characteristics of the short wave for extra long distance transmission and has made radio communication and broadcasting world-wide.

"In recounting these achievements it has been the aim to indicate how the subjects were taken up and how they were developed. Scores of other achievements might be mentioned covering methods of operation, pieces of apparatus, . . . grenades, and other war devices, and other items covered by some three hundred patents.

"Conrad's genius has had a propitious environment; the traditional inventor in the attic suffers for resources and sympathetic understanding; the modern counterpart is the organized laboratory force for industrial research.

DR. FRANK CONRAD

Edison Medalist for 1930 who received the award "for his contribution to radio broadcasting and short-wave radio transmission"

An Individualist

"Primarily, Frank Conrad is an individualist. While cooperative he has not surrounded himself with a corps of assistants. He liked to work in his little shop at home and out of his hobbies and his home work have come some of his notable achievements.

"For many years Frank Conrad's official title has been assistant chief engineer of his company (Westinghouse). A few years ago he received the honorary degree of Doctor of Science from the University of Pittsburgh. The propriety of bestowing such a degree upon one who had no other degree was questioned and met by the reasoning: Granting that his career and achievements would have merited the proposed distinction had he an E. E. degree, was it not more creditable to have made such a record without it?"

Dr. Conrad Responds

After receiving the medal from the hands of President Lee and expressing deep appreciation, Dr. Conrad responded as follows, in part:

"Our present civilization can be said to be a product of comparatively few developments. The important ones which may be mentioned in the order in which they came into the world are, (1) printing, (2) the railroad, (3) the telephone, (4) the automobile, and (5) radio. Each of these has been an influence in molding the lives of people and has changed the destinies of nations.

"From early ages, the human race knew the need of implements to further their gregarious instinct. At first, man depended on muscular effort to travel and transport his goods on land; he early developed the art of water transportation from one land to another. Mechanical developments made the railroad possible and brought about mass movement. Then the automobile came as a more individualized form of transport. Printing, the telegraph, and the telephone made possible the direct exchange of ideas without the necessity of actual physical nearness. All of this has made possible our civilization wherein the individual may have the benefit of the sum total of the knowledge and products of his fellow beings.

Broadcasting Launched Fully Developed

"The arts mentioned, with the exception of radio, are not new to this age, but their usefulness has been made effective by the development of science, the uses and development going hand in hand. Radio broadcasting is distinctive in that it was scarcely visualized before the present century, but became a possibility from the developments of present day science. It has the unique distinction of having been launched as a fully developed art. In the first year of broadcasting we had available all the artifices of the present day. It required no new conceptions to make possible its success. We have made advances in technique but they have been of a comparatively minor nature . . .

"One of the factors which made it possible for science to have ready nearly all the tools required for an entirely new art was the World War. Before the war, radio was considered as a possible rival of the telephone or telegraph, and its apparent field of greatest use was in communication from ship to shore, vessel to vessel, or with isolated spots. The desirability of communication between ships for even limited distances served as an impetus to the development of devices which would thus enable a ship in distress to call for help. The apparatus as developed before the war period effectively served this purpose although it would not make possible the use to which radio is put today. The military necessities of war times not only furnished the incentive for a further development, but what is even more important, furnished the financial support necessary for this work.

"At the close of the war we found ourselves in possession of the products of many research agencies, although there was no apparent use to which these products could be put. The tools were there but there was, so far as the world could see, no work for them to do. I personally experienced this situation in that I had facilities and equipment to carry on this art of radio communication, but no incentive to do it other than the natural fascination of working with a new tool. It is probable that by demonstrating to some of my friends the possibilities of this new instrumentality, we awakened to the fact that radio's field of usefulness was not between any two restricted points, but instead was over the widest possible area. Radio broadcasting, a new art, so came into being. . . .

"The progress of any development usually is one of slow evolution. The railroad at first was an exceedingly impractical and apparently impossible venture. . . . The telephone instruments which Bell exhibited at the Centennial Exposition in 1876 were workable devices and compared favorably with the instruments used for many years afterwards. Except for refinements that came in later years, Bell's equipment was probably the great major step in this development until the telephone borrowed from radio the vacuum tube, which device has made possible the intricate telephone systems of today.

What of Specialization?

"We should, of course, expect that any new development will progress relatively more rapidly than those that came in an earlier day, because each new development has the advantage of utilizing an accumulated storage of knowledge. We might ask: Is this store becoming greater than one individual mind can assimilate? An affirmative answer might be construed from the present tendency to specialization, but I hope we shall not specialize so thoroughly that some change in our environment will subject us to the fate of the highly specialized prehistoric animals who could not survive a change in the conditions suited to their particular existence. We, of course, may find the necessity of extreme specialization in present day sciences is not so real after all. . . "

◆

Telegraphic Speed Reaches 2,500 Words per Minute

Telegraphy is the first commercial application of electricity on record. Unlike a great many of these early developments which long since have been discarded, telegraphy still is in the course of active development. During the first twenty years this development progressed to a remarkable degree—so far, in fact, that no further advance in the art was brought out until the comparatively recent, extensive application of the vacuum tube. It is a tribute to the engineers of the time of Lord Kelvin that their work was carried out upon such a firm foundation that no further advances were made for such a long period. Five papers presented at the 1931 winter convention emphasized the efforts being put forth to increase speed and improve accuracy.

High-Speed Cables

A joint paper by J. W. Milnor and G. A. Randall, Western Union Telegraph Company, New York, showed some of the design characteristics and operating performances of high-speed ocean cables. It was demonstrated that now a transmitting speed of 1,400 letters per minute, simultaneously in both directions, is practicable; in uni-directional service a speed of 2,500 letters per minute is attainable. Indications are that the ultimate speed has not yet been reached, and that high-speed duplex operation is highly desirable, especially in cases where the installation of only one cable has been justified. However, in some cases—for example between America and Japan—the difference in time is such that most of the traffic naturally flows in one direction at a time, and it is better therefore to operate in one direction only in order to take advantage of the higher speed possible when operating that way. Usually where more than one cable is available part of the equipment is operated duodirectionally, and part uni-directionally, depending upon traffic conditions.

Interference

Any consideration of cable operating speeds, however, leads to a consideration of interference. This was shown in the other paper presented by Mr. Milnor. It is known that interference definitely limits the speed at which a cable can be operated. Such interference is caused sometimes by other nearby cables, and sometimes by power or railway systems in the vicinity of the cable terminals. The most troublesome form is that which in origin is chiefly natural, and may be likened to atmospheric disturbances commonly known as static.

The interference from natural causes is greatest at moderate frequencies, decreases with increasing depth of cable, is greatest at low latitudes, and also depends to some extent on cable design and shielding. This type of interference can be controlled to a considerable extent by installing a "sea earth" of the proper length, depending upon the local and economic conditions involved.

Cable Testing

An interesting dissertation was presented by F. B. Bramhall, Western Union Telegraph Company, New York, concerning a unique telegraph testing machine. The machine was shown to have a wide variety of uses, most important of which appears to be the measurement of distortion on telegraph lines, the study of telegraph relay operating characteristics, and the measurement of telegraph line efficiency.

The novel feature of this device is its recording mechanism through which the record is made by electrochemical action between the indicating needle and a chemically treated paper strip. The needle is in continuous contact with the paper but does not make a record until a potential is applied to it.

Private-Wire Service

A paper by W. B. Blanton, Western Union Telegraph Company, New York, dealt with the system now in use for handling messages in telegraph printer installations. This system was developed for the quick answering of calls, which is of extreme importance in high-speed transmission.

It was stated that in the new installation in New York, 1,600 circuits are being handled from 608 operating tables. The system has worked out so well that only a few seconds are required to answer a call, and the total time of completing a message has been almost halved.

R. E. Pierce, American Telephone and Telegraph Company, New York, gave some interesting facts concerning the private-wire telegraph service maintained by the Bell system. (This paper was abstracted, beginning on page 45, of the Jan. 1931 issue of ELECTRICAL ENGINEERING.)

The session was presided over by H. S. Osborne, Transmission Engineer, American Telephone and Telegraph Company, New York, and vice-chairman of the A. I. E. E. committee on communication.

◆

Higher Speeds Aim of Railway Motors

The only evening business session held in connection with the winter convention was devoted to the discussion of single-phase a-c. railway motors. The occasion was a joint meeting of the Institute's transportation committee and the Transportation Group of the New York Section.

Locomotives employing these motors have been in use by the New York, New Haven & Hartford Railroad Company since 1907, and from the standpoints of both operating experiences and maintenance costs are proving quite satisfactory. In an effort to provide for greater loads and higher sustained speeds intensive development work has been carried on in connection with these motors during the past few years. Two papers covering design details and operating characteristics were presented during this session—One by H. C. Jungk, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., and the second jointly by F. A. Pritchard and Felix Konn, both of the General Electric Company, Erie, Pa. A lively discussion followed in which almost every phase of operation with this type of motor was brought up by the numerous railway engineers present.

These two papers appear in abridged form beginning on pages 1009 and 1013 of the December 1931 issue of THE JOURNAL OF THE A. I. E. E.

High Torque vs. High Speed

Mr. Jungk stated that the prime requirements for railway motors are high starting torque and high maximum running speed. The main difficulties in achieving this with the series a-c. motor were found to be in building a motor with sufficient poles to keep the flux per pole small, and still keep the armature diameter small enough to permit the desired running speed.

In Mr. Pritchard and Mr. Konn's presentation, a number of pictures were shown illustrating the structural details of these motors. Here again was emphasized the desirability of keeping the flux per pole small in order to minimize commutation difficulties but in addition was demonstrated how the application of interpoles and compensating windings to these motors also greatly improved commutation.

In addition to the items already mentioned, the following were pointed out:

1. Operating characteristics of single-phase, series, a-c. motors compare favorably with those of series, d-c. motors.
2. Commutator peripheral velocities up to 9,000 ft. per min. now are permissible with the use of the disk-spring construction.
3. Better core materials and more compact brush holders have permitted a large number of poles with small motor diameter.
4. More compact ventilation design now is obtained.
5. The use of roller bearings is an important aid in obtaining high speed.
6. Locomotives now being built with these motors have better operating characteristics at all speeds than do steam locomotives.

It was stated that it now is practical to build locomotives with single-phase series 25-cycle, a-c. motors (in twin) for an axle loading as high as 75,000 lb., and a maximum sustained speed of 90 mi. per hr. There is every reason to believe that should higher loading and increased speed be desired these limits can be exceeded.

◆

From Inductive Interference to Inductive Coordination

Of significance is the fact that an entire session of the winter convention was devoted to a symposium covering the coordination of power and telephone plants. The session was presided over by A. E. Knowlton, associate editor of *Electrical World*, New York, and chairman of the Institute's meetings and papers committee, who said of the session:

> "Actually the symposium has done more than assemble the elements of the problem into a comprehensive perspective, and thus serve as an interpretation for both power and telephone enterprises. It has demonstrated the ability of engineers to solve within their own sphere and that of precise economics, problems which otherwise would have brought into play the incompatible procedures of law. It also has demonstrated that engineers recognize their professional obligations to make available to the populace in general the fruits of technical accomplishment at minimum cost and maximum serviceability. Of all these performances the electrical profession may justly be proud."

Pack and Gherardi Emphasize Harmony

R. F. Pack, vice-president and general manager, Northern States Power Company, Minneapolis, in his introductory remarks, preliminary to the formal presentation of the technical papers, outlined briefly the history of the subject and the activities of the joint general committee of the National Electric Light Association and the Bell Telephone System, which has guided the destiny of this coordination work since 1921. On that initial foundation the various problems involved were approached in the broadest possible spirit of cooperation, bearing in mind the fact that the object to be attained was the removal of friction and the early development of mutually satisfactory construction and operating standards for these two types of utility systems. Mr. Pack said in part:

> "It was recognized also that the public's interest is paramount and that both the power and communication utilities must be able to render their respective services to the public in an economical and efficient manner......... We know now that the foundation stones have thus been well and truly laid. It was not so much what had actually been accomplished that mattered, but that the whole spirit of the relations between the telephone and power interests had been completely changed from one of friction, distrust, suspicion, and even of enmity, to one of confidence, good-will, and a desire on the part of both to cooperate.........I am more and more convinced that this is the sound way to settle such problems and controversies arising between great interests in this country. Courts and regulating authorities approve this method because it promotes harmony and permits them to devote their time and talents to other useful purposes, and because it saves the taxpayers the material expense of costly technical hearings in which the interests of the public are in no way jeopardized."

In adding brief comments, Bancroft Gherardi, vice-president and chief engineer, American Telephone and Telegraph Company, New York, and past-president of the Institute tersely seconded Mr. Pack's remarks by characterizing the original state of affairs as "one in which the two utilities agreed on nothing, whereas now there was entire agreement as to the fundamentals involved, and a willingness to work in harmony" in solving detailed and specific problems. In emphasizing the economic value to all parties concerned including the users of utility services, of working out controversial problems on the basis of sound engineering judgment instead of fighting them out before courts and regulatory commissions, Mr. Gherardi cited the whole situation as illustrative of the broadening scope of the engineer and his work.

Technical Problems Outlined

The "Trend in Telephone and Power Practise as Effecting Coordination," discussed by W. H. Harrison, American Telephone and Telegraph Company, New York, and A. E. Silver, Electric Bond and Share Company, New York, is liberally abstracted elsewhere in this issue.

The "Status of Joint Development and Research on Noise Frequency Induction," was given by H. L. Wills, Georgia Power Company, Atlanta, and O. B. Blackwell, American Telephone and Telegraph Company, New York, who classified the factors contributing to induction in general and to noise frequency induction in particular, discussed methods of control, and outlined some of the further work to be undertaken. A similar dissertation concerning low-frequency induction was presented by R. N. Conwell, Public Service Electric & Gas Company, Newark, N. J., and H. S. Warren, American Telephone and Telegraph Company, New York, who gave a classification of factors responsible for inductive effects and discussed the various factors controlling the magnitude of induced voltages, their frequency of occurrence, and their duration and effect. Types of protective measures also were discussed at some length.

J. C. Martin, Middle West Utilities Company, Chicago, and H. L. Huber, American Telephone and Telegraph Company, New York, discussed the "Status of Cooperative Work on Joint Use of Poles," pointing out good and bad construction practises. (This paper is abstracted elsewhere in this issue.)

◆

Industrial Subjects Attract Institute Attention

Electron tubes, automatic regulators, electrical distribution systems and special types of synchronous motors were included in the discussions presented during a winter convention session devoted to industrial power applications of electrical equipment.

High-Torque Synchronous Motors

A special "Synchronous Motor with Phase-Connected Damper Winding As a Drive for High-Torque Loads," was described by M. A. Hyde, Jr., Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa. This particular type of motor was described as having been designed to meet industrial requirements for low-speed synchronous motors such as are used in the drive of grinding machinery in the cement and mining industries. This type of motor is capable of developing extremely high starting and pull-out torque although the results obtained are bound up to an unusual extent in the control equipment which of necessity is somewhat more complicated than with the ordinary synchronous motor.

Some of the problems met in the design and application of synchronous motors to meet special industrial requirements were discussed by D. W. McLenegan and A. G. Ferriss, of the General Electric Company, Schenectady, N. Y. They presented the conclusions that the design characteristics of a normal type of synchronous motor best adapted for steady-load operation should include: (1) separate d-c. excitation, (2) internal revolving field, (3) laminated salient-field poles, (4) air-gap equal to from 1.5 to 2.0 per cent of the pole pitch, (5) amortisseur winding section of sufficient heat capacity to enable the motor to start its load safely, and (6) open armature slots somewhat fewer in number than those of an equivalent induction motor. They outlined methods whereby without abandoning this basic form the electric design of a synchronous motor may be so proportioned as to meet the characteristics required for many different exacting industrial applications.

Industrial Control and Power Distribution

J. H. Ashbaugh, Westinghouse Electric & Manufacturing Company, East Pittsburgh, outlined some of the many industrial operations in which the application of automatic regulators of one kind or another could be made advantageous. He explained the fundamental theory of all regulators and pointed out that any one regulator has a wide range of applications possible, stating as an example that a voltage regulator could be used just as well as a speed regulator or a current regulator. Mr. Ashbaugh asserted that one of the greatest needs was for a fully satisfactory and dependable speed regulator, and described a newly developed carbon-pile device developed for this service.

In discussing "Electrical Distribution Systems for Industrial Plants," Walter J. McClain, electrical engineer with Louis T. Klauder, consulting engineer, Philadelphia, outlined a method of compiling distribution problems and by analyzing these, determining a solution embodying general requirements suitable for an electrical system serving industrial plants. The scope of his consideration included everything from the source of power supplied to the power-consuming devices.

W. R. King, General Electric Company Schenectady, in his paper "Electron Tubes in Industry," gave an illuminating index to some of the rapidly increasing applications of various electron tubes. He touched briefly upon the theory and characteristics of photoelectric tubes and their application, discussed briefly the theory and application of the "pliotron," and discussed at some length the theory and application of the thyratron.

C. H. Drake, general engineer, Westinghouse Electric & Manufacturing Company, and chairman of the A. I. E. E. general power applications committee, swung the gavel during this session.

◆

Traveling Waves and Lightning Effects Studied

In a winter convention session devoted to some of the problems incident to electric power transmission, two general subjects were discussed in five papers: (1) traveling waves on transmission systems and (2) lightning investigations of one character or another. The session was presided over by P. H. Chase, chief engineer of the Philadelphia Electric Company, and chairman of the Institute's transmission and distribution committee.

Continuing an extended investigation, L. V. Bewley, General Electric Company, Pittsfield, Mass., discussed further his investigation and calculations of "Traveling Waves on Transmission Systems." In the current paper Mr. Bewley presented the theory of traveling waves on multi-conductor systems and compiled a brief compendium on the general subject of traveling waves on transmission systems. The origin, shape, and general characteristics of traveling waves are discussed; equivalent circuits of terminal equipment and the corresponding reflections and refractions from such junctions were given for a large number of cases. Methods of computing a multiplicity of successive reflections by means of graphical lattices also were described. This latter is quite similar to the author's dissertation as presented at the 1930 Pacific Coast Convention at Portland, Ore.

Attenuation and Reflection

In discussing the "Attenuation and Successive Reflections of Traveling Waves," James C. Dowell, General Electric Company, Pittsfield, described a method which he had followed in segregating the individual waves from the oscillographic record of the voltage at a transition point due to the superposition of several successive reflections. In the author's opinion it is necessary to effect this separation to permit the determination of wave attenuation on a given transmission line. He stated that in the past it has not been unusual to attribute the reduction in crest value of each successive reflection to attenuation, whereas the major cause of such reduction was reflection at the terminal equipment. The author presented analyses and calculations of the information revealed in certain oscillograms of successive reflection, and stated that his calculations demonstrated that by treating the line as distortionless the behavior of artificial lightning surges on a transmission line could be computed with a reasonable degree of engineering accuracy.

To supplement laboratory information on the subject, "Impulse Tests on Substations" of the Public Service Electric & Gas Company, Newark, N. J., were reported upon by R. M. Southgate and A. S. Brookes of that company, and E. R. Whitehead and W. G. Roman, of the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., These practical tests on an operating system included the surging of a 220-kv. switching station over eight miles of overhead lines. A study was made of the effects of various amounts of connected bus and station equipment, and the effect of different arrester locations.

FIELD DATA ON LIGHTNING

Further practical data were sought in a "Lightning Investigation on a Wood-Pole Transmission Line," reported upon by R. R. Pittman, Arkansas Power & Light Company, Pine Bluff, Ark., and J. J. Torok, Westinghouse Electric & Manufacturing Company, East Pittsburgh. As a result of field tests covering a total of 38 surges occurring on a highly-insulated wood-pole transmission line, the authors concluded that harmful effects are caused only by direct strokes. Of the 38 surges recorded, one reached a crest of 5 million volts and one a crest of 4½ million volts; analysis showed that these high surges were the results of lightning striking the line and causing faults between conductors but not to ground. Records obtained indicated that surge currents varied relatively from insignificant values to 100,000 amperes. The authors conclude that insulation alone does not offer a solution to the lightning problem.

Presenting his fifth annual paper on the subject of "Lightning Experiences on the 132-Kv. Transmission Lines of the American Gas and Electric Company," Philip Sporn, chief engineer of that company, discussed and analyzed the records of his system for 1929. Upon the basis of his own analyses the author has arrived at the conclusion that:

(1) Two-circuit lines are more reliable than single-circuit lines.

(2) Two ground wires are better than one.

(3) Grading shields do not reduce line outages, but decrease line damage.

(4) Direct and induced strokes must be considered.

(5) Flashovers do not concentrate on towers of high-footing resistance.

(6) Tower footing resistance must be low if an overhead ground wire is to give effective protection.

◆

Machinery Developments Emerge From Laboratory

Five papers were presented at the machinery session of the winter convention, each recording a definite advance in the knowledge of electrical machinery performance. When asked for his impressions of the session, P. L. Alger, assistant to the vice-president in charge of design engineering, General Electric Company, Schenectady; chairman of the A. I. E. E. electrical machinery committee, and chairman of the session, said:

MERCURY ARC RECTIFIERS

"Dr. A. W. Hull of the General Electric Research Laboratory described striking improvements in mercury arc rectifiers obtained as a result of extended research work, particularly on the control of current flow from the anodes. By the use of anode heaters to provide a definite mercury vapor pressure, the use of grids to increase the arc-back potential, and by other means the current-carrying capacities of rectifiers have been greatly increased, and the frequency of arc-backs has been materially reduced. New 3,000-volt rectifiers employing these new features now are in successful operation supplying all the power for the D. L. & W. electrification. In commenting on the paper, H. D. Brown, co-author with Dr. Hull, mentioned that the research work described had enabled the current capacities of rectifiers to be more than doubled in a brief time, and enabled very high momentary overload current ratings to be given. Mr. Brown also mentioned

Substation is Built in 70 Working Days

COMPLETION within 70 working days and with an average of 75 men on the job of the substation shown in the accompanying illustrations is the record established by the United Engineers & Constructors, Inc. The station was built at North Arlington, N. J., for the Public Service Electric & Gas Company (Newark, N. J.) and it is stated that notwithstanding the speed with which the job was completed the unit costs of carrying on the work were no higher than for other structures of similar design. The building is 70x30 ft., with the outdoor structure designed to accommodate four 26.4-kv. incoming lines, twelve 4.15-kv. automatically-regulated feeders, ten street-light circuits, and two 6,000-kv-a. transformer banks. At present two 26.4-kv. lines, six 4.15-kv. lines and two street-light circuits are in service.

that there is now under construction a 10,000 ampere, 625 volt rectifier.

"Gabriel Kron of the United Research Corporation, (Long Island City, N. Y.) presented a paper on the slot effects in induction motors, giving ten definite rules to predetermine vibration, "crawling," and noise. While this subject is a familiar one, and most designers have developed fairly satisfactory rules for their own use, Mr. Kron's paper presents for the first time a compact rational explanation of all these effects.

Stroboscopic Movies

"H. E. Edgerton, of the Massachusetts Institute of Technology electrical engineering staff presented a paper on the synchronizing performance of salient pole synchronous machines. His discussion was illustrated with a stroboscopic moving picture which showed the motion of the rotor as clearly as if the observer actually were carried around with the revolving flux, thus enabling the oscillations as the rotor pulls into step to be seen plainly. The solution of the salient-pole-machine synchronizing equation never has been obtained mathematically, because of its complex form, but Mr. Edgerton put the M. I. T. integraph to work on the task and with it obtained an exact solution in a form very convenient for use by designers. Discussion of the paper indicated that the results will be of immediate practical use in enabling the load synchronizing ability of synchronous motors to be accurately predetermined.

Heat Flow in Turbines

"C. R. Soderberg, Westinghouse Electric and Manufacturing Company, described a complete theory of steady-state heat flow in large turbine generators, which he has developed. The theory is based on laying out the heat-flow paths in the form of definite thermal circuits, and converting these into equivalent electrical circuits, the solution of which are in familiar form. The proportions of the total heat dissipated from the various machine surfaces were discussed, and a future paper giving experimental results was promised.

"The last paper of the session was one dealing with the effects of transient voltages on power transformers, by K. K. Palueff of the General Electric Company. This paper is the third in a series written by the author, presenting the theory and practical results of shielding as a means of reducing the voltage concentration in transformer windings under lightning and switching surges. The first two papers dealt with two-circuit transformers solidly grounded, and grounded through an impedor, respectively, while this latest paper deals with the auto transformer. The theoretical and experimental results presented show that it is possible now, by proper shielding, to control the surge voltage distribution throughout the windings of all of these types of transformer, thus greatly reducing abnormal voltage stresses and permitting simpler insulation design."

◆

Protective Devices Improve Electric Service

Developments in circuit-interrupting devices and theory easily occupied the center of the stage in the winter convention session on protective devices; not, however, to the exclusion of presentations concerning transient stability limits of power systems and current advances in lightning arrester theory and application, which also claimed general interest.

Lightning Protection

J. J. Torok, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., described "An Experimental Lightning Protector for Insulators" the operation of which was said to be similar to that of the expulsion fuse, causing the extinction of the arc at the end of the first half-cycle when the current goes through zero value. The supporting principle is that excessive potentials will set up an arc in the confining chamber, which arc is subsequently extinguished by a deionizing effect in a remarkably brief period of time, thus clearing the system of what otherwise might be a troublesome flashover.

In "Field Tests on Thyrite Lightning Arresters Using Artificial Lightning of 1,500,000 Volts" described by K. B. McEachron and E. J. Wade, General Electric Company, Pittsfield, Mass., the authors had studied that type of arrester in experimental operation on a 45-mi. transmission line. As a result of experimental findings it is proposed that line insulation shall be limited for a distance of a half-mile back from the station at which lightning arresters are installed. Oscillograms were interpreted to show that for the traveling wave used, no protection is offered by an arrester at a distance of 2,180 ft.

System Stability

In suggesting the "Series Resistance Method of Increasing Transient Stability Limits," R. C. Bergvall, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., characterized it as an "ace in the hole" of some importance in effecting station system stability, particularly in connection with hydroelectric generators of relatively low inertia as compared with the system load inertia. He presented evidence to support his contention that synchronism could be maintained readily on a hydro system of normal proportions for any type of fault if, through a combination of high-speed circuit breaker and high-speed relay operation, a series resistor of suitable proportions could be inserted in the generator neutral lead for a brief period of time.

Circuit Breaker Trends

In discussing "The Trend in Development of Modern Circuit Interrupters," J. B. MacNeill, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., reviewed briefly the major mechanical and electrical characteristics of all important contemporary devices including some foreign types. Mr. MacNeill stated that through the use of the modern high-power testing facilities now available to engineers, many of the now novel ideas for such interrupting devices may possibly be developed commercially. It is his conclusion that the several forms of circuit interrupters not using oil and which now are assuming commercial importance, should be limited in application to insulations of 25 kv. or less, and largely for indoor service only. For higher voltages he sees little competition with the oil circuit breaker in its present greatly improved forms.

"The Oil-Blast Circuit Breaker" (see page 134, Electrical Engineering, February 1931) was described at some length by D. C. Prince and W. F. Skeats, General Electric Company, Schenectady. Extensive field and laboratory tests on this breaker itself and in comparison with other types, were described at length in a paper by Philip Sporn and H. P. St. Clair, of the American Gas & Electric Company, New York, and in a paper by R. M. Spurck and H. E. Strang, General Electric Company, Philadelphia. These latter two papers presented field and laboratory test results upon the basis of which the General Electric authors stated in part that:

"A high-voltage, high-capacity breaker now has been demonstrated to have the ability to interrupt forty short circuits up to 115 per cent of its rating in a short period of time without inspection or attention and still be in condition to operate. This would indicate that in some respects the general impression of an oil circuit breaker as an unreliable device and one requiring undue maintenance may be subject to revision. Such a development appears to meet the requirements set up only a few years ago by some operating engineers for a breaker that would operate 50 times under short circuit without requiring attention."

In commenting upon the session its chairman, Raymond Bailey, assistant electrical engineer of the Philadelphia Electric Company, chairman of the Institute's protective devices committee said, in part:

> "Discussion of the oil circuit breaker papers indicated a disagreement between the research engineers of American manufacturers, on the underlying theory of circuit interruption in oil. This frank discussion of opposing views should prove particularly valuable in arriving at the final solution of the oil circuit breaker problem."

◆

Welding Session Studies Arc Characteristics

Of importance and particular significance in the field of electric welding is the trend of research and investigation toward a better understanding of the basic fundamentals underlying the electric arc itself. While the cut-and-try method based upon field experience and laboratory tests has been responsible for some noteworthy improvements in both welding equipment and procedure it stands to reason that a more intelligent and economical solution to many of the problems of that arc may be expected when the basic fundamentals of the electric arc itself are better understood. In recognition of the prominent place occupied by electric welding in the field of engineering activities is evidenced by the fact that one entire session of the winter convention program was devoted to that subject under the chairmanship of P. P. Alexander of the General Electric Laboratory, and chairman of the A. I. E. E. welding committee.

The principal contribution of fundamental research was in the discussion of "Some Experiments With Arcs Between Metal Electrodes" presented by Prof. G. M. Shrum, University of British Columbia, Vancouver, B. C., and H. G. Wiest, Jr., General Electric Company, West Lynn, Mass. and presented by Dr. Saul Duschmann, General Electric Company, Schenectady. The paper described experiments on arcs occurring between metal electrodes in argon and other gases, in which the current was controlled by means of a kenotron. Volt-ampere characteristics of the discharge for the entire transition stage from glow to arc, or the reverse, were obtained by varying the temperature of the cathode in the kenotron. According to observation the spectrum of the discharge in the arc phase is characteristic of the cathode material, at least for the smaller current values. Results obtained led the authors to state that they did not support the assumption that a temperature effect at the cathode and the resulting thermionic emission causes the glow discharge to develop into an arc. Rather, the indication is that the resulting arc is a matter of current density of the cathode.

Arc-Welding Equipment

Arc welding generators and related equipment in one form or another were discussed at some length in three papers:

1. An Improved Arc-Welding Generator, by J. H. Blankenbuehler, Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.
2. The Neutralized Welder—A Means of Controlling Transients, by Frederick Creedy, Lehigh University, Bethlehem, Pa.
3. A System for D-C. Arc Welding, by S. R. Bergman, General Electric Company, West Lynn, Mass.

Mr. Blankenbuehler attributed most of the trouble in starting and maintaining arcs to the operating characteristics of the welding generator involved, and presented an analysis of these troubles explaining them in terms of generator design. He described equipment including a specially designed transformer built into the circuit of a welding generator in such a manner that surges due to arc variations are practically obviated.

These three papers presented various experimental data—mathematical and of other analyses—and the results of a certain amount of practical experience. Suggestions covering the use of transformers, reactors and special machine design in varying combinations, all intended to take the peaks out of the short-circuit characteristic curves of welding generators were made by the authors. The resulting general discussions and barrage of claims and counter-claims somewhat clouded the issue so far as it concerned the accurate determination of just which one of the several ideas was conceived first or worked best. However, the consensus of opinion seemed to be that the general trend of the suggested development, and certainly the objective were correct.

Welding Methods

A method for the "Resistance Welding of Motor Frames," discussed by Malcolm Thomson, General Electric Company, Lynn, Mass., involves the use of a flash-welding process which appears to be particularly successful in this application.

The author of this paper described the process of making motor frames from flat plates rolled into cylindrical form and butt-welded by the flash process; with feet welded on by ordinary arc welding. He added that these two welding methods made possible the production of motor frames from 25 to 50 per cent cheaper than with corresponding steel castings besides adding the definite advantages of greater uniformity in dimensions and structures.

Equipment and procedure for "Electric Resistance Brazing," were described by Samuel Martin, Jr., General Electric Company, Schenectady. Equipment developed includes a special portable transformer unit complete with service extension cord, leads of convenient length, and a specially-designed brazing clamp or tongs. Soft carbon blocks are used in the tongs as the heating elements, and the metallic parts to be brazed are clamped between them, receiving all of their heat according to the author, by conduction. With this equipment and the use of silver solder, joints of much greater mechanical strength, durability, and higher electrical conductivity than the more usual soft solder joints, were said to result with an actual saving in cost per joint.

◆

Research Forms Basis For Further Development

Seven subjects, principally of a fundamental nature and revealing some noteworthy results of continued persistent efforts, were presented and discussed in a winter convention session devoted to research. L. W. Chubb, assistant to the vice-president of the R. C. A.-Victor Corporation, and chairman of the Institute's research committee, presided.

Oil Characteristics Sought

"Some Electrical Characteristics of Cable Oils" were outlined by Hubert H. Race, General Electric Company, Schenectady, who divided his presentation into three parts. His first section dealt with routine measurements of d-c. resistivity and described a quartz-insulated testing cell and portable testing set for use with it, with which it is claimed that absolute resistivity between 1×10^9 and 1×10^{13} ohms per cm.^{3} can be measured at any temperature up to 150 deg. cent. In his second section he gave data concerning the variation of the apparent d-c. conductivity of a heavy cable oil with potential gradient and with temperature showing that the conductivity is constant only for very low gradients. His third section was a summary of variations of dielectric coefficients and dielectric loss, occurring with temperature and frequency as observed for a viscous cable oil. His analysis shows that the total dielectric loss is the sum of two components, one due to conduction and the other qualitatively explained by Debye's theory of polar molecules.

In a companion paper, J. B. Whitehead, of The Johns-Hopkins University, Baltimore, presented some of the results of his further investigation into "The Conductivity of Insulating Oils." Dr. Whitehead concluded that:

(1) Certain high-grade insulating oils have electrical characteristics similar in type and comparable in magnitude to those of the carefully refined, poorly-conducted liquids used in physical research.

(2) In the purest state they show a definite though brief dielectric absorption.

(3) The initial dielectric absorption increases with decrease of temperature and thus is associated with the viscosity.

(4) The dielectric loss at less than 60 cycles alternating stress is determined definitely by the continuous-current characteristics within the interval from zero to 0.1 sec.

(5) The initial absorption conductivity and subsequent decay are not completely accounted for by the residual impurities as frequently stated.

In collaboration with Dr. Whitehead, Prof. W. B. Kouwenhoven, The Johns-Hopkins University, presented a paper on on "Fundamental Properties of Impregnated Paper." The authors jointly emphasized the importance of the initial conductivity of impregnated oils as distinguished from the final conductivity and stated that higher conductivity is reflected in increased losses arising from both reversible and irreversible dielectric absorption.

Vacuum Tubes Control Traffic

Traffic-control equipment operated automatically by light beams, one of the many and ever-increasing commercial applications of the versatile vacuum tube was described by R. C. Hitchcock, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa. The equipment is described fully elsewhere in this issue.

Commutation in Hydrogen

Two papers having to do with research looking toward the improvement of rotating machinery, were presented by R. M. Baker, and G. M. Little, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa. As the result of experimental data collected by Mr. Baker concerning "Commutation and Current Collection in Hydrogen," he has come to the conclusion that:

(1) A commutator machine designed and adjusted for good commutation in air will operate satisfactorily and give good brush life in hydrogen.

(2) If a commutator machine must spark in hydrogen the brush life may be increased materially by maintaining less than 10 per cent humidity.

(3) Contact resistance between carbon brushes and commutator may be lowered materially by the introduction of hydrogen.

(4) Carbon or graphite brushes cannot be operated satisfactorily on plain tool-steel slip-rings running in hydrogen and that

(5) contact drop between a carbon or graphite brush and a brass slip-ring may be as much as ten times higher with the ring running in air as it is with the ring running in hydrogen.

Mr. Little has been investigating "The Application of the Helical Groove to Slip-Rings and Commutators," and has come to the conclusion that the helical groove:

(1) provides a means for forcing a more uniform distribution of current over the brush face; (2) permits the escape of air trapped under a brush; (3) prevents local spot heating under overload conditions; (4) raises the content drop of the brush, improving commutation and (5) in some cases increases brush life.

A rather comprehensive paper by C. G. Suits, General Electric Company, Schenectady, covering his "Studies in Non-Linear Circuits" and a discussion of the "Magnetic Circuit Units as Adopted by the I. E. C." prepared by Dr. Arthur E. Kennelly, Harvard University, brought the research program to a close.

◆

Railroad Electrification Problems Are Discussed

Of the five papers presented at the transportation session of the winter convention, two may be said to be of general interest in the field of transportation, and three of somewhat specific interest in that field. In commenting upon the session, Sidney Withington, electrical engineer of the New York, New Haven & Hartford Railroad, chairman of the Institute's committee on transportation, and chairman of the session said, in part:

> Mr. Moreland's paper was especially timely in that it followed closely the inauguration of one of the notable projects of the year in railroad electrification. The comprehensive description, together with the inspection trip, presented to the Institute members a somewhat unusual opportunity to learn the details of the Lackawanna electrification. Mr. Drake's paper on the Sperry fissure detector car also was timely and may well be considered a tribute to the late Elmer A. Sperry.

The five papers presented were:

1. Lackawanna Suburban Electrification, by E. L. Moreland, Jackson & Moreland, Boston.
2. Motive Power for Suburban Electrification, by Charles Kerr, Jr., Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.
3. Transverse Fissure Detector Car, by H. C. Drake, Sperry Products, Inc., Brooklyn, N. Y.
4. Inclined Catenary Calculations, by B. M. Pickens, Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.
5. Design of Catenary System for Cleveland Union Terminal, by N. F. Clement and E. E. Richards, Cleveland Union Terminals Company.

Mr. Moreland's paper is rather fully abstracted elsewhere in this issue.

Mr. Kerr dwelt upon the problems peculiar to suburban electric railway operation where the number of cars required during rush hours varies from two to six times that required for off-peak service. He pointed out that trailer cars may be used to advantage under these circumstances without reducing the schedule speed more than three or four per cent.

In discussing this paper, H. F. Brown of the New York, New Haven & Hartford Railroad stated that for twenty years his road had used a system similar to that which Mr. Kerr outlined, and that it worked out very well.

Faulty Rails Revealed

In introducing Mr. Drake, Mr. Withington paid tribute to the late Emler A. Sperry who was directly responsible for the development of the rail-fissure detector described in Mr. Drake's paper, and one of the last of the many contributions which Mr. Sperry has made to civilization. This presentation was illustrated by a moving picture which showed the effectiveness of the device in locating all kinds of transverse rail faults and fissures before the point of actual rail breakage. As many as 24 fissures have been found in a single rail section.

In Mr. Pickens' absence Mr. Kerr read an abstract of his paper. This paper demonstrated a unique method for calculating the space factors involved in the design and layout of inclined overhead catenary construction as required in electric railway work. His method provides for a smooth, continuous curve of contact wire from span to span, lying in a horizontal plane.

The Cleveland Union Terminal is a station which is used jointly by the several railroads entering Cleveland, and is located in a central part of the city; the electrification, which is of the 3,000-volt d-c. type, extends from the terminal some distance out in both directions, covering a total of 59 track miles. The last paper of this session explained the design details of the overhead power supply used on this electrification. The scheme consists of tangent-chord compound catenary system. Parabola formulas were used for the calculations and where feasible were made up in the form of charts.

In discussing all of the papers of this session, D. C. Jackson brought out the point that the problem involved in electric railway construction and operation was primarily one of transportation, and that the electrical engineering work involved was chiefly a means to the furthering of that end. According to Mr. Jackson the most important question to be answered is an economic one; "will the improvements possible through electrification justify themselves from a cost standpoint?"

◆

Winter Convention Attracts 1,589 Registrants

With devotion of its special attention to inductive coordination, and industrial applications of electricity and electrical devices, the winter convention, held Jan. 26-30, inclusive in the Engineering Societies Building, 33 West 39th Street, New York, N. Y., attracted 1,589 persons, officially registered, but heavy attendance at the sessions indicated the presence of many others. As revealed by the following tabulation nearly every geographic district was represented:

District	Registrants
New York City and Foreign (3)	730
Middle Eastern (2)	515
North Eastern (1)	231
Great Lakes (5)	47
Canada (10)	42
Southern (4)	11
South West (7)	10
North Central (6)	3
Total	1,589

New York Sights are Shown to Convention Delegates

In addition to its wealth of technical papers covering a wide variety of timely and important subjects, the winter convention program offered a multiplicity of entertainment features in keeping with the quality of its technical program. Inspection trips included the recently electrified divisions of the Delaware & Lackawanna Railroad and its power supply facilities; the new Hudson River Bridge, the longest single-span structure in existence; and the Empire State Building, the world's highest. Also available to all conventioners, practically at their own convenience, were such features as the Westinghouse Lighting Institute; the Chrysler Building (exceeded in height only by the Empire State Building) with its vertical distribution network; modern photo lithograph and newspaper plants; the Electrical Testing Laboratories; and various immense steam-electric generating plants, not to mention the museums and exhibitions peculiar to New York.

Particular attention was given to the women's entertainment program which included charmingly conducted luncheons and bridge teas, to say nothing of inspection trips specially chosen for their unique attractiveness, including a visit to the White Star Line Steamship "Majestic" and a practical demonstration of television at the Bell Telephone Laboratories.

For the men, if attendance be any index, the informal buffet dinner and supper was a huge success, and there truly was "standing room only" at the "The Frolics of 1931," the nine-part headliner stage show put on by the entertainment committee. Concluding the social affairs in connection with the convention was the annual dinner dance held in the Grand Ballroom of the Hotel Astor, Thursday evening, January 29, and presided over by that genial personage, President Lee.

◆

A. I. E. E. Directors Meet During Convention

The regular meeting of the Board of Directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, Wednesday, January 28, 1931, during the annual winter convention of the Institute. Those present were:

President—W. S. Lee, Charlotte, N. C.

Past-presidents—R. F. Schuchardt, Chicago, Ill; Harold B. Smith, Worcester, Mass.

Vice-presidents—W. S. Rodman, Charlottesville, Va.; C. E. Sisson, Toronto, Ont.; G. C. Shaad, Lawrence, Kans.; I. E. Moultrop, Boston Mass.; H. P. Charlesworth, New York, N. Y.; T. N. Lacy, Detroit, Mich.

Directors—F. C. Hanker, East Pittsburgh, Pa.; E. B. Meyer, Newark, N. J.; J. Allen Johnson, Buffalo, N. Y.; A. M. MacCutcheon, Cleveland, Ohio; J. E. Kearns, Chicago, Ill.; F. W. Peek, Jr., Pittsfield, Mass.; C. E. Stephens, New York, N. Y.; A. B. Cooper, Toronto, Ont.; A. E. Knowlton and R. H. Tapscott, New York, N. Y.

National treasurer—W. I. Slichter.

National secretary—F. L. Hutchinson, New York, N. Y.

Present by invitation—H. A. Kidder, New York, chairman of the committee on the engineering profession.

Actions Ratified

Minutes of the directors' meeting of December 4, 1930, were approved.

Reports of meetings of the board of examiners held December 23 and January 20 were presented, and the actions taken at those meetings were approved. Upon the recommendation of the board of examiners, the following actions were taken upon pending applications:

391 Students were enrolled.

486 applicants were elected to the grade of Associate.

27 applicants were elected to the grade of Member.

25 applicants were transferred to the grade of Member.

4 applicants were transferred to the grade of Fellow.

The board ratified the action of the finance committee in approving for payment, monthly bills amounting to $33,253.52 for the month of December and $30,159.22 for the month of January.

The annual report of the president of the U. S. national committee of the International Commission on Illumination was received and ordered filed, and payment of the Institute's annual contribution of $300 to the U. S. committee was authorized.

In accordance with Sec. 22 of the constitution, N. T. Wilcox was exempted from future payment of dues, thereby being added to the list of "Members for Life."

The national secretary reported that the members in arrears for dues for the fiscal year which ended April 30, 1930, were dropped from the membership list on December 31, 1930, with the exception of those who had requested an extension of time for the payment of these dues. The members dropped totaled 739 including 2 Fellows, 40 Members, and 697 Associates.

1932 Institute Meetings

The committee on coordination of Institute activities reported a recommended schedule of national and district meetings for the calendar year 1932, based upon applications for meetings received from district executive committees in response to a request of the coordination committee that such applications be filed by January 1,1931. The schedule included all requests for meetings that were received. The Board voted to approve the recommended schedule of meetings for 1932, as follows:

January 25-29, Winter convention, New York, N. Y.

March 14-16, District meeting (No. 5), Milwaukee, Wis.

May (early), District meeting (No. 1), Providence, R. I.

June 20-24, Summer convention, (location to be decided later).

Aug. 29-Sept. 2, Pacific coast convention, Vancouver, B. C.

October, District meeting (No. 2), Baltimore, Md.

November, District meeting (No. 4), Memphis, Tenn.

Upon request of the executive committee of the North Eastern District, the dates of the Rochester district meeting were changed from May 6-9, 1931, to April 29-May 2, 1931.

NEW SECTION

Upon the recommendation of the sections committee, the territory of the Louisville section was extended to include the remainder of Woodford County and all of Fayette and Jessamine Counties, and a new section was authorized; namely, a Florida section, to include as its territory the entire state.

As recommended by the committee on student branches, authorization was given for the organization of student branches at the University of Illinois, Urbana, Ill., and Rice Institute, Houston, Tex.

STANDARDS SPECIFICATIONS

Upon recommendation of the standards committee, approval was given to the following specifications developed by the sectional committee on insulated wires and cables:

Specification No. 12—Weatherproof (weather-resisting) Wires and Cables.

Specification No. 12A—Heat-Resisting Wires and Cables.

Specification No. 4—Code Rubber Insulation for Wire and Cable for General Purposes.

These specifications were approved for publication in the regular A. I. E. E. series of pamphlets dealing with standards and related material.

MISCELLANEOUS ACTIONS

Amendments to the By-laws were adopted, changing the following references therein to conform to changes in names which have already gone into effect: "Journal of the A. I. E. E." changed to read "Electrical Engineering," "Engineering Foundation, Inc." changed to read "United Engineering Trustees, Inc.," "Engineering Societies Research Board" changed to "The Engineering Foundation."

Appointment of two representatives of the Institute on the Council of the American Association for the Advancement of Science for the year 1931 was referred to the president.

The designation of delegates to attend the annual meeting of the American Academy of Political and Social Science, Philadelphia, April 17-18, 1931, was referred to the president.

A communication from the Museum of Science and Industry, Chicago, enclosing an outline of proposed exhibits in the museum on the subject of electric power and asking for comments, was referred to the Chicago Section of the Institute.

It was voted to hold the March meeting of the board of directors in Pittsburgh, during the district Meeting of the Institute, March 11 to 13.

Other matters were discussed, reference to which may be found in this and future issues of ELECTRICAL ENGINEERING.

◆ ◆ ◆

Some Winter Convention Discussions are Summarized

A SUMMARY of some of the many discussions presented at the first four sessions of the winter convention is given herewith. Only discussion submitted in writing in accordance with A. I. E. E. rules governing it is summarized; complete discussion together with all papers so approved will be published in the TRANSACTIONS. A list of papers presented was published in the January issue of ELECTRICAL ENGINEERING. Later discussions will be summarized in subsequent issues.

Symposium on Telegraphy

E. R. Shute discussed "Newfoundland-Azores Duplex Cable." Referring to Fig. 1 of the paper he pointed out that this cable forms the diagonal of a quadrilateral, and in the event of a cable failure or stoppage of any of the cables the resulting triangular circuit layouts tend to maintain continuity of service.

INTERFERENCE

A. W. Breyfogel discussed "Submarine Cable Telegraphy—Influence of Interference." He stated that the paper gives the theoretical as well as the practical means for determining the magnitude of the effect that transient forms of interference will have upon the receiving instrument; but it does not give the practical means available for minimizing the effect of such disturbances. Where interference is present, it is always of advantage to tune the receiving equipment to the lowest practical frequency consistent with reception of satisfactory shaped signals. This generally permits reception at a higher speed than might otherwise be obtained.

TRANSMISSION TESTING MACHINE

H. H. Haglund in his discussion on "Telegraph Transmission Testing Machine" stated that the machine has many other uses besides the testing of telegraph transmission. It is used for comparing the speed of oscillating systems of comparatively low frequency such as electrically-driven tuning forks. Mr. Haglund told of five methods which in the past have been so commonly employed for this purpose.

P. B. Shanck in his discussion on "The Telegraph Transmission Testing Machine" believed that the machine is particularly well suited to the investigation of distortion which, with a regularly-recurring signal, oscillates through a definite cycle so as to form a regular pattern as is the case with a-c. interference.

PRINTING CONCENTRATOR

C. M. Brentlinger, in discussing "A Printing Telegraph Concentrator" explained that the concentrator was developed to give very fast service without incurring prohibitive operating expense. He also pointed out in his discussion the advantages of splitting circuits into several 100- or 200-wire units instead of putting them all in one large unit. These are as follows: space limitations imposed by the need of other equipment before each operator, a saving in cable expense, a possible saving effected in the provision of equipment to care for future growth, and greater flexibility of operation.

PRIVATE-WIRE SERVICE

H. H. Nance discussed "Modern Practises in Private-Wire Telegraph Service" with special reference to the operation of voice-frequency carrier telegraph systems on channels of carrier-telephone systems. He cited the value of the flexibility of this method that resulted when line trouble encountered during a recent severe storm in the mid-west caused the re-routing of service.

Symposium on Coordination of Power and Telephone Plant

J. J. Smith in discussion of "Trends in Telephone and Power Practise As Affecting Coordination" did not believe that the references in the paper to the use of transformers with graded insulation and Y-Y transformers were representative of the more usual type of practise on power systems. A large proportion of 220-kv. transformers are so constructed but for 66-kv. systems and above, a large proportion of the transformers have sufficient insulation on the neutral end of the winding to permit the insertion of considerable impedance between line and ground. He also pointed out that the use of delta-Y instead of the Y-Y connection is by far the more common practise.

NOISE-FREQUENCY INDUCTION

In discussion of "Status of Joint Development and Research on Noise-Frequency Induction," J. J. Smith predicts the introduction of the use of vacuum tube devices on a fairly large scale within the next decade. He also calls attention to fact that some of the work of the Joint General Committee is of interest in other fields, such as electrical machinery, elimination of street noise, etc.

M. D. Hooven in discussion of the papers in the symposium called attention to the educational value of the material presented, and in particular, with reference to the problem of low-frequency induction. He also cited the importance of cooperative advance planning which was expressed in the last three papers of the symposium.

W. W. Lewis read a discussion prepared by L. T. Robinson on the papers in the symposium and which brought out the fact that a similar problem exists in the relation of the use of radio to other electrical industries. The three factors defined in the papers—namely "Influence Factor," "Susceptiveness Factor" and "Coupling Factor"—also exist and have the same importance in the radio communication field.

LOW-FREQUENCY INDUCTION

H. S. Phelps discussed "Status of Joint Development and Research on Low-Frequency Induction." He remarked "that the paper should be most helpful to one called upon to outline the essential feature of low-frequency induction." In further discussion he commented upon the benefits of the shielding effects that may be derived from the proper use of ground wires.

L. P. Ferris discussed "Status of Joint Development and Research on Low-Frequency Induction." Showing the effect of diminishing-earth conductivity on the permissible closeness of power and telephone lines with the aid of a curve prepared from field data, and by considering a hypothetical case.

H. M. Trueblood discussed "Joint Development and Research on Low-Frequency Induction." He explained that the division of the work is such that some of the project committees are engaged upon questions relating very largely to telephone systems, while others are giving their attention to questions which concern power systems almost exclusively. Each project committee is made up of members representing both industries so that the power and telephone engineers are getting pretty well acquainted with each other's problems.

D. H. Gage discussed "Status of Joint Development and Research on Low-Frequency Induction," with relation to the interference on telegraph lines as caused by power lines. He believed that there is a field for investigation in cases where unexpected interference results from an exposure of a communication line to an apparently well-balanced power circuit, with very little current in the neutral. He also cited a situation where short exposures at different places on the same line which while alone would not cause serious interference, but when they were combined in certain ways, materially affected the operation of communication circuits.

JOINT POLE USE

D. H. Gage also discussed "Status of Cooperative Work on Joint Use of Poles" and brought out the question of joint-line agreements with particular reference to the character of circuits on jointly-used poles; also the question of liability. He believed engineers should give these questions careful consideration, even though they might seem outside the scope of an engineering study.

Protective Devices Session Discussion

STABILITY

S. B. Crary in discussion of "Series Resistance Method of Increasing the Transient Stability Limit" pointed out that the practical gain to be realized from the use of the series-braking resistor decreases with faster switching time.

J. W. Anderson in his discussion of this paper gave some actual figures of acceleration serving to emphasize the marked tendency of hydroelectric generators to overspeed upon loss of load immediately after a short circuit occurs. This was pointed out by Mr. Bergvall in his paper.

G. D. Floyd, discussing "Series Resistance Method of Increasing the Transient Stability Limit," believed that from the calculations and tests covered by the paper, zero resistance at point of fault might be inferred. He pointed out that the inference is justified for three-phase faults, but in cases of single- and double-line-to-ground faults where there might be high resistance at fault location, the added resistance in the generator leads might cause a drop in the unit's speed sufficient to make it lose synchronism.

H. S. Phelps in discussion of "Series Resistance Method of Increasing Transient Stability" took exception to the idea expressed in the paper that instead of trying to solve the stability problem by building lightning-proof lines consideration might be given to building lower-cost transmission lines that would be expected to flash over. He pointed out that this conclusion must be considered in conjunction with the views expressed in the symposium on coordination of power and telephone plants.

CIRCUIT INTERRUPTING DEVICES

Philip Sporn discussed "Trend in Development of Modern Circuit Interrupters" and commented upon the advances made within the last three or four years in the oil circuit breaker field. He expressed disappointment, however, in the lack of progress in the development of an oil-less interrupting device.

C. L. Fortescue in discussion of "Trend in Development of Modern Circuit Interrupters" commented on the various principles of oil circuit breakers, emphasizing the noiselessness and smoothness with which the deion circuit interrupter and the deion-grid oil circuit breakers operated.

R. M. Spurck in discussion on this paper commented upon the attempts that have been made to eliminate oil from high-duty circuit-interrupting devices. He believed that although workable devices not requiring oil have been developed there is a question whether or not the entire elimination of oil does not introduce some handicaps which are greater than those it has tried to eliminate.

Philip Sporn in discussion of "Oil Circuit Breaker Tests—Philo 1930" pointed out that the present OCO-two minutes-OCO breaker duty cycle does not meet actual operating conditions or practise. He expressed a need of bringing Institute standards and service practise into closer conformity.

J. B. MacNeill discussed "The Oil-Blast Circuit Breaker" and he pointed out that some of the ideas advanced in the paper seemed to be at variance with well-established facts about arc behavior He believed that at some point on the arc. tip the arc would form a crater which would move about but never permit the arc to envelop the tip. In consequence the oil and gas would rush past the arc, partly into the hollow electrode and partly out the explosion pot throat, through the regular contact clearance instead of passing through the arc as claimed in principle in the paper.

In discussion on "Field Tests on Standard and Oil-Blast Explosion Chamber Oil Circuit Breakers," H. M. Wilcox cited a number of tests that have been made on oil circuit breakers equipped with deion grids. The average performance of the deion-grid circuit breakers on all of these tests ranged from 7,000 to 8,000 volts per inch, with a grand average of 7,500 volts per inch of total arc length as compared with a performance of 4,050 volts per inch on the 140-kv. tests of the oil-blast circuit breaker under average circuit conditions.

Power Transmission Session Discussion

Traveling Waves

C. L. Fortescue's discussion on "Traveling Waves on Transmission Systems" was read by J. J. Torok. He expressed interest in finding that in making computations, Mr. Bewley used the method of successive reflections; he further stated that to determine proper clearances, etc., for lightning calculations this method is simple and direct and is sufficiently accurate.

H. L. Rorden's discussion of "Traveling Waves on Transmission Systems" was read by J. G. Lusignan, Jr., who emphasized the importance of experimental verification of mathematical treatment and described tests of traveling waves made with the cathode ray oscillograph. The results obtained with line conditions as given by Fig. 10D of Mr. Bewley's paper were illustrative of the general correlation found.

O. Ackerman's discussion of "Attenuation and Successive Reflections of Traveling Waves" was read by E. Beck, and pointed out the results of this paper as pertaining to attenuation which deviated from any previous results reported. Figs. 12 and 13 of the paper indicate that in a travel of 85 microseconds, corresponding to about 16 mi. surges decrease only 10 to 20 per cent. Previously reported tests indicated that surges over a 16-mi. stretch attenuate to about one-half their original value.

L. V. Bewley read a discussion which E. W. Boehne prepared on this paper. In the light of information gathered from field observations it pointed out one additional way in which corona affects the attenuation of voltage surges.

Lightning Investigations

L. V. Bewley in discussion of "Impulse Tests on Substations," commented upon the fact that the paper gives a number of oscillograms showing the effect of bus structure, breakers, and transformers, on traveling waves; however, conclusions were not drawn as to the characteristic effect of station equipment on traveling waves.

L. V. Bewley in discussing "Lightning Investigation on a Wood-Pole Transmission Line" gave the definitions and derivations of the self- and mutual-surge impedances of the equivalent conductor which replaces any number of conductors in parallel.

C. L. Fortescue's discussion on "Lightning Investigation on a Wood-Pole Transmission Line" was read by Mr. Garnett. He pointed out that Fig. 11 in the paper cannot possibly be a cathode ray oscillograph record of what happened on the line itself as on either side of the lightning experimental station 4½ mi. distant, the line was provided with fused drain points having a flashover of from 800 to 1,000 kv. for long surges. He asserted that the record was false, and that it was due to something influencing the cathode ray oscillograph circuit directly instead of through the line.

E. C. Williams read a discussion prepared by C. E. Ambelang and F. E. Andrews on "Lightning Investigation on a Wood-Pole Transmission Line." In this they reported their experience with lines of voltage lower than those of 110-kv. investigated by the authors, but their experience substantiates that cited in the paper; their conclusions also correspond.

J. J. Torok discussed "1929 Lightning Experience on the 132-Kv. Transmission Lines of the American Gas and Electric Company." He analysized the author's data, interpreting it on a direct stroke basis. In further discussion J. J. Torok stated that the paper shows markedly the importance of adequate ground-wire protection. He predicted that if two ground wires properly located were used instead of one on the Turner-Logan Line, the number of flashovers would be reduced from thirteen to one or two.

R. N. Southgate discussed "1929 Lightning Experience on the 132-Kv. Transmission Lines of the American Gas and Electric Company." He described a case where a lightning stroke was photographed, and then located as having struck the ground about 2,000 ft. from the station. The location of this stroke was placed within 350 ft. of a 220-kv. line to which an oscillograph was connected, and within 275 ft. of the live 132-kv. line. A surge was not recorded and a trip-out on the 132-kv. line did not occur, which indicates immunity of lines of this nature from induced strokes and lends support to the direct-stroke theory.

L. V. Bewley discussed "1929 Lightning Experience on the 132-Kv. Transmission Lines of the American Gas and Electric Company." One of the points which he explained and illustrated mathematically was that a flashover on the bottom conductor might be due to a direct stroke on the ground wire rather than an induced surge.

A summary of some of the discussions of the papers presented at the later sessions of the convention will be given in a subsequent issue.

A. S. T. M. To Meet in Pittsburgh

A regional meeting and dinner of the American Society for Testing Materials will be held in Pittsburgh at the William Penn Hotel March 18, 1931. The program constitutes a symposium on welding, and the Pittsburgh section of the American Welding Society is in cooperation.

The sessions include:

1. General survey of welding processes
2. Welding processes applicable to aluminum
3. The quality of materials for fusion welding
4. Modern applications of arc welding
5. Recent developments in gas welding and cutting
6. Stethescopic examination of welded products
7. Tests of welding made by the Watertown Arsenal
8. Magnetic methods of testing butt welds
9. Fatigue and impact testing of welded products
10. Welded inspection.

◆

Rutgers University Plans European Tours

Russia with its new experiments and many aspects of engineering as well as of industrial management, will be the object of practical observation and study by a party which will tour that country during the summer of 1931 under the leadership of Parker H. Dagget, dean of the college of engineering at Rutgers. It is planned also that a party of educators and travelers studying social conditions will make the tour through Russia and Europe under the direction of Prof. N. C. Miller, head of the Rutgers University Extension Division.

The tour now is being organized with headquarters at Rutgers University, New Brunswick, N. J., the expectation is to visit in addition to Russia, cities in Germany, Austria, France, Sweden, Finland, Denmark, Switzerland, and Poland. The entire group is scheduled to sail from New York July 4, 1931.

◆

Turbine Inventor Chas. Parsons Passes Away

Sir Charles Parsons, K. C. B., inventor of the steam turbine design bearing his name, passed away February 11, 1931, while aboard ship on a West Indies cruise. He was 76 years old.

The steam turbine upon which he began experiments in 1884 represents but one of his many contributions to science and mechanics. Sir Charles evoked much comment while visiting in the United

States in 1924, when he made a plea for the founding of an international corporation to dig twelve miles into the crust of the earth. He contended that the water power supply of the world was being depleted rapidly and that it might be possible to harness the heat that lies deep beneath the surface of the globe.

During the World War Sir Charles served on numerous government committees. He was knighted in 1911. Later he served terms as president of the Institute of Physics, the British Association, and other similar organizations. Among the many scientific awards received by him was the medal of the Royal Society, of which he was a fellow. Sir Charles was chairman of the numerous industrial corporations which manufactured his turbines and other inventions.

◆

Lehigh University to Hold Welding Symposium

The subject of welding and its progress each year in process and equipment. is comprehensively handled in the welding symposium presented annually by Lehigh University. This year the symposium will be held on Friday, March 27th; and one of the important papers will be that presented by J. C. Hodge of the Babcock & Wilcox Company. Mr. Hodge has made important improvements and contributions to the art of welding, and is in position to speak authoritatively concerning this important branch of engineering activity.

In addition to the discussion, there will be many demonstrations of all of the different types and methods of welding; and this year a special feature, which will reflect the most recent progress in the art in accordance with scientific development, will demonstrate the equipment and process of testing welds by gamma rays.

The success of the symposium in advancing the art of welding has been evidenced in the past by the heavy attendance of engineers from many industrial districts.

◆

Research Assistantships Offered by U. of Illinois

To assist in the conduct of engineering research and to extend and strengthen the field of its graduate work in engineering, the University of Illinois maintains fourteen research graduate assistantships in its engineering experiment station. Two other such assistantships have been established under the patronage of the Illinois Gas Association. These assistantships, for each of which there is an annual stipend of $600 and freedom from all fees except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics, or applied chemistry.

Appointments are made and must be accepted for two consecutive collegiate years of ten months each, at the expiration of which period, if all requirements have been met, the degree of Master of Science will be conferred. Half of the time of a research graduate assistant (approximately 900 clock hours for each ten-month period) is required in connection with the work of the department to which he is assigned, the remainder being available for graduate study.

Nominations to these positions, accompanied by assignments to special departments of the Engineering Experiment Station, are made from applications received by the Director of the Station each year not later than the first day of April. Preference is given those applicants who have had some practical engineering experience following the completion of the undergraduate work. Appointments are made in the spring, and they become effective the first day of the following September. Additional information may be obtained by addressing The Director, Engineering Experiment Station, University of Illinois, Urbana, Illinois.

◆

Business Conditions Reflected by "Indicators"

The following table of "selected business indicators" gives a comprehensive view of the business situation at the beginning of February. It is a new and easily understood tabulation, devised by a conference of statisticians in industry which meets once a month under the auspices of the National Industrial Conference Board, Inc., New York.

The conference represents more than 8,000 industrial firms throughout the United States and its statistics are compiled each month for the preceding month.

SELECTED BUSINESS INDICATORS

	Jan. 1931 expressed as percentage of:		
	Dec. 1930	Oct. to Dec. 1930 average	Jan. 1930
Basic Production			
Auto. U. S. A. and Canada	114	122	64
Building contracts	91	81	70
Steel ingots[1]	119	103	65
Pig iron[1]	103	89	60
Bituminous coal	98	95	78
Machine tool shipments	88	89	41
Machine tool orders	100	93	37
Copper, N. and S. America	96	91	77
Cotton cloth, standard	108	105	78
Newsprint paper	102	97	87
Electric power	102	100	94
Basic Consumption			
Steel orders unfilled	105	112	92
Cooper shipments	80	87	86
Machine tool orders unfilled	88	80	32
Crude rubber	133	119	78
Silk taken by manufacturers	89	98	68
Stocks on Hand			
Crude rubber	103	109	116
Copper in U. S. A.	98	97	121
Raw silk in storage	89	98	68
Newsprint paper	104	95	149
General Trade			
Carloadings, total	106	89	86
Merchandise and miscellaneous	104	86	88
Advertising lineage, newspapers	93	86	86
National magazine cost	71	64	87
Retail Trade			
Department stores[2]	106	103	93
Mail order[2]	86	84	
5 and 10 cent stores[2]	115	115	105
Business failures, number	131	149	120
Business failures, liabilities	113	145	155
Wholesale prices, general[3]	90	97	83
Wholesale prices, raw materials	101	98	80
Wholesale prices, semi-manufactured	97	96	78
Wholesale prices, finished	98	96	86

1. Average daily basis.
2. Corrected for monthly variation.
3. Estimated.

North Eastern District Meets at Rochester Apr. 29

A four-day meeting of the North Eastern District of the A. I. E. E. will be held at Rochester, N. Y., April 29 to May 2, 1931. Headquarters will be at the Sagamore Hotel.

The city of Rochester possesses many features which should prove most interesting to visitors attending the meeting; geographically located on the southern shore of Lake Ontario, and built upon the banks of the Genesee River falling 261 ft. in three cataracts within the city limits, it has all the natural resources which go to make a city attractive. From an industrial point of view Rochester is an important manufacturing center. It is the home of such well-known plants as the Eastman Kodak Company, the General Railway Signal Company, and the Stromberg-Carlson Telephone Manufacturing Company.

Technical Sessions

Four technical sessions which have been tentatively planned by the local committee will be built around: (1) Selected Subjects, (2) Research, (3) Symposium on Noise in Electrical Machinery, and (4) General Distribution. At these sessions many interesting papers will be presented, several of them dealing with the subject of lightning in relation to distribution systems.

A list of the papers to be presented and more complete details of the meeting will appear in the April issue of Electrical Engineering.

◆

Mining Engineers Register Another Successful Annual Meeting

With a general attendance of over sixteen hundred members and guests the 140th annual meeting of the American Institute of Mining and Metallurgical Engineers meeting in the Engineering Societies Building, 29 West 39th St., closed February 19th proclaimed by all in attendance as thoroughly successful. The year's progress in mining and metallurgical fields had been definitely and interestingly presented and discussed; entertainment occupied a liberal portion of the program and two medal awards and one prize award conferred for distinguished service.

William H. Pierce, vice-president of the American Smelting & Refining Co. who has made abundant contributions to the art of mechanical casting, electrolytic refining, and copper converting, notably the Smith-Pierce basic converter, which has long stood supreme, received the James Douglas Medal for his numerous designs and improvements of devices and machinery for smelting, refining and rolling copper. This medal was established by anonymous donors to commemorate the work of Dr. James Douglas, twice president of the Institute of Mining engineers and an earnest worker for the cause. The William Lawrence Saunders medal, awarded "for distinguished achievement in mining" was conferred upon Francis William Maclennan, the second McGill University man to win it since it was established in 1927.

The Robert Woolston Hunt prize and medal, won by Doctor E. C. Bain in 1929, this year went to one closely associated with Doctor Bain in much of his work—Edmund Sharington Davenport, research engineer for the Eastern Malleable Iron Company, the Westinghouse Lamp Company, and now with the United States Steel Corporation at Kearny, N. J. His studies have dealt specifically with cast iron, tungsten, thorium, and the transformation of autinite at constant subcritical temperatures.

The election of officers for the ensuing year makes Robert E. Tally, executive vice-president in charge for the United Verde Copper Company, New York, director and president; Howard N. Eavenson, consulting engineer, Pittsburgh, and H. A. Guess, managing director of the American Smelting & Refining Company of New York, directors and vice-presidents; and Louis S. Cates of the Phelps Dodge Corporation, Karl Eilers, consulting metallurgist, S. R. Elliott, general superintendent of the Cleveland Cliffs Iron Company, Ishpeming, Michigan, H. G. Moulton, consulting engineer, New York, and William Wraith, of the Inspiration Consolidated Copper Company and the Andes Copper Mining Company of New York, directors.

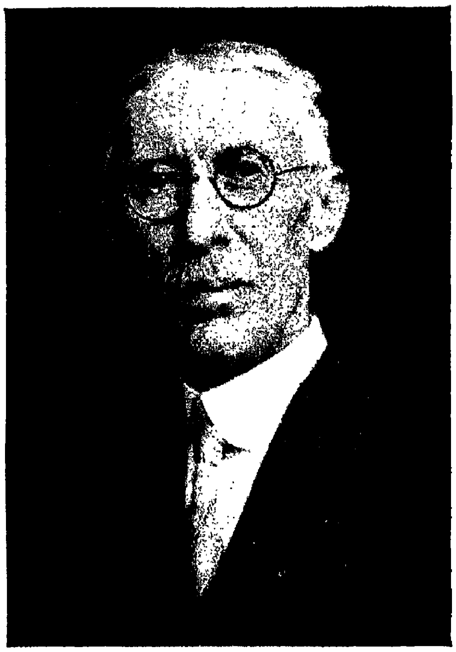
Personal

William J. Foster is Awarded Lamme Medal

Dr. William J. Foster of Schenectady, N. Y., has been awarded the Lamme Medal of the American Institute of Electrical Engineers "for his contributions to the design of rotating alternating current machinery," and will be presented at the summer convention of the Institute which is to be held in Asheville, N. C., June 22-26, 1931.

William James Foster, Sc. D., consulting engineer (retired) General Electric Company, was born in Argyle, N. Y., September 17, 1860. His college preparatory work was done partly alone with borrowed textbooks and partly at an academy and a boarding school. After graduating from Williams College with an A. B. degree in 1884, he remained a year for advanced work in mathematics. During the next five years, he taught high school subjects, and made an intensive study of physics. The degree of Master of Science was conferred upon him by Cornell University in 1891, following a year of graduate study.

In the summer of 1891, Dr. Foster began his engineering career in the Thomson-Houston Works in Lynn, Mass.; a few months later he was assigned work on synchronous converters. On October 1, 1892, he became assistant engineer, and began at that time a close association with Dr. H. G. Reist which continued for thirty-seven years.



DR. WILLIAM J. FOSTER

Beginning in 1893 and extending through several years, his association with Dr. Steinmetz also was very close. During this period, Dr. Foster assisted in general improvements, developed retardation tests, and originated tests for measuring short-circuit losses. His drafts of test methods involving heat runs, overloads, temperature rises, etc., through Dr. Steinmetz were submitted to the Committee on Standardization of the A. I. E. E. and adopted as standards.

During most of his engineering life he has had general charge of the electrical designs of a-c. rotating machines, built by the General Electric Company. For about twenty-five years, beginning in 1895, he made practically all the calculations on the most important generators that were built by this company.

He joined the Institute in 1907, and was transferred to the grade of Fellow in 1916. He served as a member of the Committee on Electrical Machinery for ten years, and was Chairman during the year 1928-29.

His other memberships include the American Association for the Advancement of Science and Phi Beta Kappa.

◆

E. C. Stone Named Vice-President Philadelphia Co.

E. C. Stone, vice-president of the Institute, was appointed on February 1st assistant to the senior vice-president of the Philadelphia Company and its subsidiaries.

Mr. Stone is a native of Charlestown, N. H.; following graduation from Harvard University in 1904, he immediately became affiliated with the Westinghouse Electric & Manufacturing Company at East Pittsburgh as an engineering apprentice, later entering the engineering department engaged in the design of transformers. In 1911 he joined the Allegheny County Light Company in Pittsburgh which two years later became the Duquesne Light Company. In 1913 he organized the system operating department for the lighting of the city of Pittsburgh, acting until 1919 as system operator; then he was promoted to the office of technical assistant to the general manager. In 1922 he became planning engineer, a position in which he organized and developed the planning division. In 1927 he again received promotion to become system development manager.

E. C. STONE

Mr. Stone has just relinquished his duties as chairman of the engineering national section of the National Electric Light Association. He is a member of the advisory board of the International Electrotechnical Commission and a member of the Association of Iron and Steel Electrical Engineers and the Engineers Society of Western Pennsylvania.

◆

E. A. Hester, formerly planning engineer of the Duquesne Light Company has been placed in charge of the newly formed operating systems planning division of the company's vice-president and general manager's office, taking over the previous duties of E. C. Stone, former system development manager.

◆

B. M. Jones, formerly general engineer of the Duquesne Co. has been promoted to planning engineer, the position vacated by Mr. Hester, and will be directly responsible for the planning and orderly development of company system and the preparation of the annual capital improvement budget.

◆

Richard H. Ranger has entered consulting engineering practise, to specialize in radio, acoustics, and general electronic technique. With him are four of his former associates in the Radio Corporation of America. The R. C. A. retains him in matters of radio picture transmission.

Previous to joining the R. C. A. ten years ago, Major Ranger was Commanding Officer of the Signal Corps Laboratories at Fort Monmouth. His first work in the R. C. A. was building the long wave, transatlantic receiving stations of that company—notably that at Riverhead, Long Island. Subsequently, he built the first R. C. A. broadcasting station at Aldene, N. J., and started the broadcasting stations, WJZ on top of the Aeolian Building, and of WRC in Washington. He was identified also with the first ship-to-shore telephony on the S. S. *America.*

◆

Frank W. Smith, vice-president, general manager, and a director of the United Electric Light & Power Company and chairman of the board of the New York and Queens Light and Power Company, two of the five companies composing the New York Edison System, has been made a vice-president of the New York Edison Company. Mr. Smith is very much of a pioneer in the arc light field; when a lad of thirteen he engaged with the United States Illuminating Company, and by the time he had reached the age of sixteen, had become general clerk. In 1889 when the United Company was formed, he was paymaster, and at twenty-four, assistant auditor. Since 1912 he has been a vice-president of the Brush Electric Illuminating Company, having priorly served both this company and the United Company as secretary.

Clarence L. Law, general commercial manager of the New York Edison Company and assistant to vice-president of the Yonkers Electric Light & Power Company was elected president of the Electrical Association of New York at its recent annual meeting. As general secretary, director, treasurer, and president of the Illuminating Engineering Society, Mr. Law is a prominent figure in the electrical industry; he also has served the National Electric Light Association as chairman of numerous committees, and has been active in the Empire State Gas and Electric Association, American Institute of Electrical Engineers, Association of Edison Illuminating Companies, and American Association for the Advancement of Science.

◆

Roy Wilkins, according to ratification by the stockholders of the Pacific Electric Manufacturing Company, San Francisco, has been appointed its vice-president in charge of engineering. Mr. Wilkins joined the organization Jan. 1, 1928 in a consulting capacity, and for fifteen years prior to that date had been associated with the Pacific Gas and Electric Company; he has conducted many hydroelectric and high-voltage experiments and is well known to the industry for his corona research and his knowledge of high-voltage oil circuit breakers. He has always taken an active part in Institute affairs and those of the Pacific Coast Electrical Association.

◆

Douglas Montgomery, who was previously electrical engineer in Pasadena, California, has been for the past year, lacking some three weeks, in Buenos Aires with the Western Electric Company, Inc. of Argentina, (local foreign subsidiary of the Electrical Research Products, Inc.), operating as service supervisor for the company's Buenos Aires district. Mr. Montgomery has been "seeing to it that from 18 to 38 motion picture installations kept their company voices in any one of the several languages—Spanish, French, English, or German."

◆

Frank B. Steele, until recently vice-president and general manager of the Utica Gas & Electric Company, Utica, N. Y., has opened offices in that city for the general practise of engineering. Mr. Steele will specialize in heating, power, electrical and pumping problems, tests and reports on private industrial power plants, design of steam, hydro, heating and pumping plants and transmission, substations and distribution systems. After eleven years in its service he resigned as an officer of the Utica utility two years ago. He is a member of the

A. I. E. E., N. E. L. A., and the American Gas Association.

◆

L. M. Cargo, Mountain States representative of the Westinghouse company, Denver, Colo., whose election to the presidency of the Electrical League of Colorado is announced, is a real veteran in the electrical business, having been continuously with the same firm for 42 years, 33 of which have been spent in the Rocky Mountain region.

◆

Byron E. White of the Utica Gas & Electric Company has been named division engineer of the central division of the Niagara Hudson Power System. Mr. White's appointment follows more than 25 years' experience in the engineering department of the Utica Gas & Electric Company.

◆

J. G. Corrin, who has been with the transformer division of the Allis-Chalmers Manufacturing Company in Los Angeles, has resigned to join American Brown Boveri Company, Inc., in New York City, as a special transformer representative. Mr. Corrin went to the Pacific Coast from New York seven years ago; he was formerly district manager for the Pittsburgh Transformer Company, later joining Allis-Chalmers when that company took over the Pittsburgh company.

◆

Robert S. Hale, long associated with the Edison Electric Illuminating Company of Boston, has resigned. Mr. Hale was a graduate of Harvard and obtained his M. E. degree at Cornell. From 1893 to 1895 he was assigned to special engineering work with the Boston Edison Company and from 1910 has been in charge of the special research department, where, as an authority on utility economic problems, he became widely known throughout the electrical industry.

◆

S. P. Larsen, for the past four years northwest manager of the Line Material Company, Portland, Ore., has been made district sales manager in the Northwest for Hubbard & Company, pole-line hardware manufacturers of Pittsburgh, Chicago, and Oakland, Calif. Mr. Larsen will transfer his headquarters from Portland to Seattle.

◆

Otto Snyder, president of New York Power & Light Corporation and in charge of eastern division activities of the Niagara Hudson Power Corporation System at the February 5th meeting of its board of directors was elected a vice-president of Niagara Hudson system.

◆

George E. Deming, works manager of the Philadelphia Storage Battery Company, has been named as its executive vice-president and Walter E. Holland, chief engineer, becomes vice-president in charge of engineering.

◆

J. R. Murphy has received appointment as manager of the General Electric Company at Spokane, succeeding Bernhard Olsen, who has been transferred as local manager of the company's Indianapolis office.

◆

Harvey H. Hoxie has been appointed San Francisco manager of the Joslyn Company of California. Mr. Hoxie has been associated with the San Francisco office of the company for some time.

◆

Mathew S. Sloan, at the organization meeting of the board of directors of the New York Edison Company, was reelected president.

Obituary

C. L. Doub, assistant engineer of the Reading Company and an Associate of the Institute (1922), died at the age of thirty-four, January 21. Mr. Doub was born at Washington, D. C., and was a graduate of Johns Hopkins University. In 1918 he became substation operator for the Hagerstown & Frederick Railway, Maryland, but continued to study in a Westinghouse graduate student course, which he completed in 1920. Prior to joining the Reading Company, he was assistant engineer of the Illinois Central Electrification Work. His affiliation with the Reading Company dated back to 1927.

◆

Harry B. Alverson, for the past thirty years a member of the Institute, and for a long period identified with the Buffalo General Electric Company as its electrical engineer, died on January 25th after an illness of several weeks. He had left the Buffalo General Electric shortly before he was taken ill and was apparently well on the road to recovery when he suffered a relapse.

A native of Portage, Wisconsin, he was graduated from the University of Wisconsin in 1893. This was followed by a course at Cornell University.

He was an active member of the Institute's Niagara Frontier Section, and his death terminates a long and useful professional career.

◆

Elwood F. McLaughlin, district manager of the central station department of the southeastern district of the General Electric Company, Atlanta, Ga., died in the local hospital of that city on January 8th, following an attack of pneumonia. He was a prominent and popular member of the Institute's Atlanta Section; one upon whom the Section's officers always could depend for wholehearted cooperation. Mr. McLaughlin was born in Philadelphia and at the time of his death was forty-seven years of age. He was graduated with the class of 1905 from Pennsylvania State College and immediately entered the steam turbine testing department of the General Electric Company at Lynn, Mass.

He was a member of the A. S. M. E., had served as chairman of its Atlanta section, and always took a leading and active part in all local enterprises of both A. I. E. E. and A. S. M. E. plans. He was a member also of the Atlanta Athletic Club, entering into its work with the same vigor and enthusiasm which typified all of his affiliations. He first joined the Institute in 1922.

◆

John Lundie, president of the Lundie Engineering Corporation, New York City, and an Associate of the Institute since 1899, died at his home on Seventy-Second Street after an illness of several weeks. He was 73 years old,—a noted consulting engineer and inventor of many railway devices bearing his name:—the Lundie tie-plate, rheostat, duplex rail anchor and the "telfer," a combined electrical hoist and traveler. Mr. Lundie was born in Arbroath, Scotland, obtained his early education there, and received his Bachelor of Science degree from Edinburgh University in 1880. This was supplemented by an honorary degree of Doctor of Science conferred by the same university in 1902. From 1873 to 1877, while still pursuing his studies, he was engaged in harbor work at Dundee. Immediately after leaving the university at Edinburgh, he came to this country, spending the next four years employed in railroad engineering in Oregon and Washington. From 1884 to 1890, municipal work in Chicago claimed his attention;

this was followed by three years of bridge construction work. In 1893 he began his practise as consulting engineer.

Doctor Lundie was member of the American Society of Civil Engineers, the American Association for the Advancement of Science, the American Institute of Consulting Engineers, the American Iron & Steel Institute, the Knights Templars, the New York Railroad Club, the New York Athletic Club and was a Fellow of the Royal Society of Arts.

◆

O. E. Huebner, electrical engineer of Russell & Stoll Company, New York City, and an Associate of the Institute (1918) died recently. He was born in Halle, Germany, in the year 1880. Much of his later time has been devoted to research problems, the dissemination of some of his attained results being made through the columns of *Engineering News*. The pycnotic substance theory and its practical application, another of Mr. Huebner's investigations, found publicity in *Technologist*, organ of the German American Technical Societies.

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the addresses as they now appear on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the Secretary at 33 West 39th St., New York, N. Y.

Davis, R. H., Westinghouse E. & M. Co., East Pittsburgh, Pa.

Dawson, Leonard L., 98 Looker Ave., Springfield, N. J.

A. DiLucci, Box 1051, Chicago, Ill.

Gale, R. E., 706 N. 19th St., Boise, Idaho.

Charles T. Gilliam, Central Power & Light Co., Frost Nat'l. Bank Bldg., San Antonio, Tex.

Kigar, D. F., 1403 Minnie St., Port Huron, Mich.

Lieb, Adolph W., N. Y. Edison Co., 393 7th Ave., New York, N. Y.

Mahnke, E. Chris, 1400 E. 53rd St., Chicago.

Prehn, Victor N., 940 Broad St., Newark, N. J.

Sherwood, W. E., Kew Gardens, 2700 Que St. N. W., Washington, D. C.

Sliney, David, 11 Orchard St., Cranford, N. J.

Van Wyck, P. V. R., Summit, N. J.

Vreeland, F. P., 110 E. 176th St., New York.

Williams, Clifton S., Research Lab., Westinghouse E. & M. Co., East Pittsburgh, Pa.

Local Meetings

Gaseous Tubes For Illumination Purposes

On March 3, 1931, the Illumination Group of the New York Section will hold a meeting on the subject of "Gaseous Tube Lighting,"—of great interest at present when so many noteworthy developments of it have taken place within the last few months. To bring section meetings up to date on a matter which is receiving so much attention a symposium has been arranged. The three speakers all intimately connected with this phase of electrical engineering, to each present a fifteen-minute résumé accompanied by striking demonstrations; also, there will be ample opportunity for open discussion. The subjects and speakers will be as follows: "A Brief Résumé of the History of the Development of Gaseous Tube Lighting," by D. C. McFarlan Moore, consulting engineer; "High-Tension Cold Cathode Gaseous Conduction Lamps," by Leo Beck, chief engineer, Claude Neon National Laboratory; "Hot-Cathode Gaseous Conduction Lamps," by Ray D. Mailey, vice-president, General Electric Vapor Lamp Company.

The meeting will be held at 7:30 p. m. in Room 1, Fifth Floor, Engineering Societies Bldg., 33 West 39th Street, New York, N. Y.

◆

Intercommunication For Ships at Sea

The Communication Group of the New York Section will hold a meeting on the evening of March 10 for the discussion of "Communication Facilities of Ships at Sea." Two speakers have been selected to present the subject as follows: "Ship-to-Shore Radio Telephone Systems," by Frederick R. Lack, Bell Telephone Laboratories, Inc., New York, N. Y., and "Ship-to-Shore Radio Telegraph Systems," by George H. Clark of the Radio Corporation of America, New York, N. Y. There will be ample time for discussion. The meeting will be held in the auditorium of the Bell Telephone Laboratories, 55 Bethune St., (corner of West Street) New York, N. Y., and will be called to order at 7:30 p. m.

By courtesy of the Laboratories, dinner will be served in the cafeteria from 6:00 p. m. on, to members and guests at a charge of 75 cents, and during the period preceding the meeting sound pictures will be presented in the auditorium.

Developments In X-Ray Science

Dr. A. Mutscheller, director of research of the Westinghouse X-ray Company, will be the speaker at the next general meeting at the New York Section to be held at 8:15 p. m. on March 27 in the Engineering Auditorium, 33 West 39th Street, New York, N. Y.

Renowned for his contributions in the field of X-ray, Doctor Mutscheller will trace the progress from early beginnings, pointing out some of the problems which have been overcome in bringing this science up to its present highly developed state. He will describe some of the recent and outstanding accomplishments—among them the hot-cathode high vacuum valve which has made possible the generation of extremely high voltage direct current—and will discuss the various applications of the modern X-ray in the industrial and scientific world.

The lecture will be followed by a demonstration of the Lenard cathode ray tube showing some of the more spectacular results achieved today by the X-ray.

Future Section Meetings

Cleveland

March 19, 1931—Industrial Applications of Vacuum Tubes and Photoelectric Cells, by E. L. Manning, General Electric Research Laboratories, Schenectady, N. Y.

April 16, 1931—Human Relations in Industry, by Whiting Williams. Joint meeting with Student Branch of Case School of Applied Science, at which two papers will be presented by students.

Detroit-Ann Arbor

March 17, 1931—The Sound of a Shadow, by J. B. Taylor, General Electric Co.

April 21, 1931—1,000-Deg. Turbine, by Paul W. Thompson, Detroit Edison Co. Meeting to be held at the Detroit Edison Auditorium.

Lehigh Valley

March 27, 1931—Adventures in Science, by E. L. Manning. Meeting to be held at Sterling Hotel, Wilkes-Barre, Pa.

April 24, 1931—Ladies' Night, to be held at Americus Hotel, Allentown, Pa.

Niagara Frontier

March 20, 1931—Subject and speaker to be announced later.

April 17, 1931—Art of Engineering, by Mr. Dohner, Westinghouse Electric & Mfg. Co.

Seattl

March 17, 1931—Annual joint meeting of the Founders' Societies with program in charge of the American Society of Civil Engineers.

April 21, 1931—Annual joint meeting with the A. I. E. E. Student Branch of the University of Washington. Program under the auspices of the students.

Sharon

March 3, 1931—Recent Interesting Aeronautical Developments, by Lieutenant S. P. Mills, War Department, Wright Field, Dayton, Ohio.

Spokane

March 27, 1931—Program by local members as follows: Service and Services, by G. S. Covey; Standard Meter Equipment, by J. G. Finley; Relay Applications to Feeder Protection, by C. F. Norberg.

Toledo

March 20, 1931—Industrial Applications of Vacuum Tubes and Photoelectric Cells, by E. L. Manning, General Electric Laboratories, Schenectady, N. Y.

Past Section Meetings

Akron

Excitation Systems and Excitation Problems, by James F. Foote, Allied Engineers, Inc. January 8. Attendance 115.

Atlanta

The Responsibilities of the Engineers, by R. V. Wright, managing editor, *Railway Age*, and president, A. S. M. E. W. L. Stanley, Seaboard Air Line Railway, described the important problems of railroads. Joint meeting with the A. S. M. E. and A. S. C. E., preceded by dinner. February 3. Attendance 85.

Boston

Possible Application of High Tension D. C. Transmission, by H. R. Summerhayes, General Electric Co. Mr. Mr. Summerhayes outlined the development work his company is doing on thyratron tubes, and explained by the use of slides the action within the tubes and how they would be used on a transmission line. January 13. Attendance 300.

Cincinnati

George W. Bason, Condit Electrical Mfg. Corp., presented a talk on the various factors involved in circuit breaker operation. Illustrated with slides and motion pictures showing actual arc interruptions made under oil in heavy glass tanks. Dinner preceded the meeting. December 11. Attendance 102.

Cleveland

Future Power Development and Distribution in the Cleveland Metropolitan Area, by H. L. Wallau, Cleveland Electric Illuminating Co. Having described the generating equipment used by the above Company in 1901, Mr. Wallau outlined and illustrated the development and progress of the system from that period to the present day. January 22. Attendance 115.

Columbus

Some New and Interesting Developments in Engineering and Research by C. K. Lee, Westinghouse Electric & Mfg. Co. Illustrated. Also, moving pictures showing modern mechanized mining. January 31. Attendance 60.

Connecticut

Machine Switching Mechanism, by O. C. Levy, Automatic Electric, Inc. Illustrated with slides and a demonstration of the Strowger automatic telephone. Meeting held at Dunham Laboratory, Yale University. January 16. Attendance 98.

Denver

General Aspects of the Boulder Canyon Project, by E. B. Debler, U. S. Reclamation Bureau. Illustrated with lantern slides. January 16. Attendance 56.

Erie

History and Art of Paper Making, by Henry J. Obermans, Hammermill Paper Company. Many exhibits on display. December 16. Attendance 118.

Fog Flying and Development of Electrical and Magnetic Instruments for Blind Flying, by E. G. Haven, General Electric Co. Dinner in honor of the speaker preceded the meeting. January 20. Attendance 118.

Fort Wayne

Dance. January 23. Attendance 80.

Indianapolis-Lafayette

The Production of Copper, by E. S. McConnell, Anaconda Wire & Cable Co. Moving pictures showing the production of copper, starting at the mine and carrying through the various stages to the finished wire, tube, and sheet, were presented. Dinner preceded the meeting. January 23. Attendance 42.

Ithaca

Some Engineering Considerations of Talking Movie Apparatus, by Herbert Belar, R. C. A.-Victor Co. The underlying principles of sound picture systems and functions of each component part were explained in detail. January 23. Attendance 150.

Kansas City

The Engineers Place in the Community, by Rev. Earle A. Blackman, Sponsor, Kansas City Youths' Forum;

Specialty, by B. J. George, Kansas City Power & Light Co. December 23. Attendance 51.

Some Recent Developments in Lightning Protection, by I. P. Monseth, Westinghouse Electric & Mfg. Co.;

Futuristic Trend in Switchgear Equipment, by A. J. Peterson, Westinghouse Electric & Mfg. Co. Illustrated. January 28. Attendance 76.

Los Angeles

The Small but Mighty, by Dr. H. D. Arnold, Bell Telephone Laboratories, Inc. Considerable discussion followed. January 27. Attendance 271.

Madison

Symposium on Methods of Increasing the Load Factor of a Power Distribution System. Speakers—S. M. Coe, Wisconsin Power & Light Co. and Harold E. Koch, Hevi Duty Electric Co. Discussion followed. January 21. Attendance 43.

Memphis

The New City Water Works Plant, by Major Thomas H. Allen, consulting engineer. Discussion followed. January 13. Attendance 24.

Mexico

The Exploitation of Saltpeter in Chile, by E. F. Lopez, National Import Co.;

Car Lighting by Electricity in the National Railways of Mexico, by R. C. Rodriguez, National Railways of Mexico. Illustrated with charts. January 13. Attendance 41.

The Applications of Electricity in Sugar Mills, by E. I. Brown; Mental Calculations, by E. Leonarz, Jr., Mexican Light & Power Co. February 3. Attendance 34.

Milwaukee

A New System of Speed Control for A. C. Motors as Applied to Auxiliary Power Stations, by Fraser Jeffrey, Allis-

Chalmers Mfg. Co. Illustrated with slides. Discussion followed the talk. January 7. Attendance 205.

Arc Welding Generators and Their Application, by K. L. Hansen, Northwestern Mfg. Co. Mr. Hansen traced the history, application of arc welding, necessary apparatus, and latest developments in the art. Discussion followed. February 4. Attendance 53.

Minnesota

Analysis of Circuit Breakers under Short Circuit, by George W. Swallow, American Brown Boveri Co., Inc. Illustrated with motion pictures. January 28. Attendance 150.

Nebraska

The Development and Application of Radiant Energy, by T. Tennyson Harris. January 19. Attendance 25.

Oil Circuit Breaker Phenomena, by George W. Swallow, American Brown Boveri Co., Inc. February 4. Attendance 50.

Niagara Frontier

Application of Electric Power in Railroad Transportation, by S. T. Dodd, General Electric Co. Illustrated with slides and motion pictures. Informal dinner in honor of the speaker was held at the Hotel Statler. January 16. Attendance 60.

Philadelphia

Smoker at the Penn Athletic Club. February 9. Attendance 200.

Pittsburgh

Some Recent Work of the Bureau of Standards, by Dr. G. K. Burgess, Director, Bureau of Standards. Moving pictures and a demonstration of the theremin followed. Midwinter dinner meeting held jointly with the Engineers Society of Western Pennsylvania. January 13. Attendance 277.

Pittsfield

Yucatan and Its Ancient Civilization, by Colonel E. H. Thompson. Illustrated with lantern slides. January 13. Attendance 850.

Electrotherapeutics, by Dr. William Bierman, New York Physical Therapy Society. Illustrated. January 26. Attendance 175.

With Byrd to the Bottom of the World, by Dr. Laurence Gould, University of Michigan. Illustrated with moving pictures. February 3. Attendance 990.

Portland

Building of Condit—Yakima 110 Kv. Line, by C. S. Knowles, Pacific Power & Light Co.;

New Developments in High Speed Oil Circuit Breakers and Relays, by E. C. Curtis, General Electric Co. December 16. Attendance 80.

The Small but Mighty, by Dr. H. D. Arnold, Bell Telephone Laboratories, Inc. Dinner in honor of the speaker preceded the meeting. January 15. Attendance 220.

Providence

Aims and Objects of the Institute, by Professor Harold B. Smith, Worcester Polytechnic Institute. Dinner preceded the meeting. December 9. Attendance 40.

The Electrical Development of the Fifteen Mile Falls Hydroelectric Project, by E. W. Dillard, New England Power Association. Illustrated with lantern slides and motion pictures. Dinner in honor of the speaker preceded the meeting. January 7. Attendance 150.

St. Louis

Radio System of the St. Louis Police Department, by Professor R. S. Glasgow, Washington University. E. J. Bonnesen, Bell Telephone Laboratories, Inc., gave an interesting account of the new broadcast station KMOX. January 21. Attendance 180.

San Antonio

Air Conditioning of a Modern Office Building, by T. M. Cunningham, Carrier Engineering Corp. Following the address, those present inspected the air conditioning apparatus in the Milam Building. January 26. Attendance 35.

San Francisco

The Small but Mighty, by Dr. H. D. Arnold, Bell Telephone Laboratories, Inc. Illustrated. Dinner preceding the meeting held at the Engineers' Club. January 23. Attendance 450.

Seattle

The Small but Mighty, by Dr. H. D. Arnold, Bell Telephone Laboratories, Inc. January 19. Attendance 130.

Sharon

Audible Light, by John B. Taylor, General Electric Co. Demonstrations of applications of the photoelectric cell. February 3. Attendance 320.

Spokane

The Small but Mighty, by Dr. H. D. Arnold, Bell Telephone Laboratories, Inc. January 12. Attendance 200.

Syracuse

Aids to Aerial Navigation, by Charles F. Green, General Electric Co. November 17. Attendance 167.

Radiation Energy—Sun and Artificial Rays, by Paul Luckenbach, General Electric Co. January 12. Attendance 249.

Toledo

Power Transmission and High-Voltage Insulators, by A. O. Austin, Ohio Brass Co.;

Regulation on Distribution Systems, by W. T. Lowery, Toledo Edison Co. Illustrated. January 16. Attendance 90.

Toronto

Artificial Transients of Transmission Lines with Particular Reference to Performance of Lightning Arresters, by K. B. McEachron, General Electric Co. Illustrated with slides. January 23. Attendance 110.

Urbana

Physical Properties and Problems of Dielectrics, by Professor V. Karapetoff, Cornell University, and Professor J. Kunz, University of Illinois. January 13. Attendance 175.

Utah

Research Developments, by H. T. Plumb, General Electric Co. Apparatus for demonstration purposes on display. January 19. Attendance 84.

Vancouver

Practical Aspects of System Stability, by F. A. Hamilton, Jr., General Electric Co. Discussion followed. February 2. Attendance 51.

Washington

Industrial Applications of Vacuum Tubes, by E. L. Manning, General Electric Co. Mr. Manning described early and recent developments of vacuum tubes and discussed present and possible future industrial applications. Dinner in honor of the speaker held at the Cosmos Club. January 13. Attendance 249.

Cables for the Transmission of Power, by I. T. Faucett, General Cable Corp. Illustrated with slides and moving pictures. Dinner preceded the meeting. February 10. Attendance 97.

Past Branch Meetings

University of Akron

Theory and Application of Diverter Pole Generators, by N. Dickinson, Student;

Amateur Radio, by S. Liebowitz, Student. Accompanied by a demonstration of a short-wave code transmitting set. January 14. Attendance 14.

Alabama Polytechnic Institute

Oil Electric Locomotives, by K. R. Clark, Westinghouse Electric & Mfg. Co. January 8. Attendance 8.

Discussion of means to increase student participation at meetings. January 29. Attendance 7.

General discussion of Branch activities. February 5. Attendance 12.

University of Arkansas

Television, by Hugh Nelson, Student. Film—"A Tell You How Story of Telephotography." February 3. Attendance 30.

Armour Institute of Technology

Lightning Investigation on Transmission Lines, by William Drigot, Student. January 12. Attendance 38.

Illumination, by O. P. Cleaver, Westinghouse Lamp Co. Illustrated with slides. January 26. Attendance 64.

University of British Columbia

Automatic Sulphur Dioxide Testing, by M. Saunders, Student;

The Development of the Incandescent Lamp, by D. Smith, Student. Discussion followed. December 6. Attendance 10.

Inspection trip to the Haro Street substation of the B. C. Electric Railway Co. January 10. Attendance 14.

Electrical Precipitation, by E. M. Kershaw, Branch Secretary;

The Life of Michael Faraday, by E. H. Full, Student. January 20. Attendance 12.

Bucknell University

Prospective Relation of the Hoover Dam to Electrical Power, by L. H. Spangler, Student;

Faraday and His Work, by O. R. Sterling, Branch chrirman. January 19. Attendance 10.

California Institute of Technology

The Electrical Distribution System of Pasadena, by E. L. Bettanier, Pasadena Municipal Light and Power Bureau. Luncheon preceded the talk. January 23. Attendance 40.

University of California

After a discussion of Branch activities three films were presented as follows: "The Manufacture of X-ray Tubes," "Bituminous Coal," and "The Manufacture of Salt." Joint meeting with the A. S. M. E. Branch. January 28. Attendance 81.

Case School of Applied Science

Dinner meeting at which G. A. Sanow, Branch chairman, outlined the activities at the Institute's district meeting held in Philadelphia; F. A. Green spoke about the advantages of membership; and William Thomas, Instructor, discussed his experiences while employed by the General Electric Company in the Testing Department. January 8. Attendance 30.

University of Cincinnati

Michael Faraday, by Carl Heyel, Student;

Recent Trends and Developments in Power-Plant Practises, by D. Brown, Union Gas & Electric Co. Refreshments served after the meeting. February 4. Attendance 27.

Clarkson College of Technology

The Field of Chemical Engineering in Electrical Engineering, by Professor Hecker. Refreshments served. January 13. Attendance 26.

Colorado Agricultural College

Photoelectric Cell, by W. R. Carmack, Student;

Analysis of Electric Heat Treating, by L. Dougherty, Student; A. C. Holden, Student, related his experiences while employed by the Crocker-Wheeler Electric Manufacturing Co. at Ampere, N. J. January 12. Attendance 16.

University of Colorado

Talks on the Hoover Dam Project in the Colorado River Canyon, by E. B. Debler, hydrographic engineer; B. W. Steele, engineer in charge of the dam design; and L. N. McClellan, chief electrical engineer of the power plant. Meeting sponsored by the Bureau of Reclamation, U. S. Department of the Interior. Joint meeting of all engineering societies. January 7. Attendance 208.

Appraisals, by Juston H. Haynes, Lloyd-Thomas Co. January 21. Attendance 28.

Life of Faraday, by J. E. Gorochow, Student;

Life of Joseph Henry, by William Wildhack, Student;

The Thyratron, by Paul Huber, Student. Film—"Through the Oil Lands of Europe and Africa." Refreshments served. February 4. Attendance 60.

Cooper Union

Fuses, Their History, Construction, and Causes of Failure, by L. E. Edwards, Bussman Mfg. Co. January 14. Attendance 60.

Drexel Institute

Television, by E. K. Cliver, Branch Chairman. January 13. Attendance 26.

University of Florida

Operation of the Automatic Telephone, by J. L. Sanders, Student;

Electrical Equipment for Overhead Cranes, by E. Menendez, Student. February 9. Attendance 26.

Iowa State College

Business meeting. January 20. Attendance 42.

Discussion and adoption of By-laws. January 27. Attendance 21.

Televox and Electric Eye, by H. B. Stevens, Westinghouse Elec. & Mfg. Co. Joint banquet with the Iowa Section. February 6. Attendance 410.

University of Iowa

Film—"The Single Ridge." January 21. Attendance 36.

Electric Elevators, by Mr. Hathaway, Student. February 4. Attendance 46.

Kansas State College

Film—"Frozen Credits." Nomination of officers for second semester. January 15. Attendance 106.

Restoration from an Electric Shock, by L. L. Naus, U. S. Bureau of Mines. Election of officers. December 13. Attendance 69.

Lewis Institute

Business meeting. January 13. Attendance 22.

Massachusetts Institut of Technology

Inspection trip to the Edgar generating station of the Edison Electric Illuminating Co. of Boston. January 14. Attendance 40.

Michigan College of Mining and Technology

Experiences with the General Electric Company, by Mr. Howell, Instructor. Motion pictures were shown on the uses of compressed air in industry. January 14. Attendance 21.

Transformers, Their Use, and Methods of Construction, by A. G. Rogers, Student;

Substations, by W. D. Stewart, Student. January 28. Attendance 18.

Michigan State College

Short talk by Professor W. A. Murray, Counselor, on the advantages of membership in the Institute. January 8. Attendance 30.

Business meeting. January 13. Attendance 18.

Discussion of plans for the electrical show. January 27. Attendance 18.

Business discussion. February 10. Attendance 17.

University of Michigan

Power System Development, by S. M. Dean, Detroit Edison Co. January 14. Attendance 65.

School of Engineering of Milwaukee

Audio-Amplification in Public Address Systems and Broadcast Studios, by N. J. Richard, Student. Film—"Blasting the Water Highways of America." A review of business conditions of the past year was outlined by Karl Werwath, Student. January 14. Attendanc 85.

University of Minnesota

Inspection trip through the Northern States Power Company's High Bridge Plant in St. Paul. December 3. Attendance 75.

Taxation as a Measure of Valuation of a Public Utility for the Purpose of Establishing a Rate Base, by John Roe, Student;

Sale Price as a Measure of Valuation of a Public Utility for the Purpose of Establishing a Rate Base, by L. A. Rovelsky, Student. January 13. Attendance 52.

Mississippi A. & M. College

Film—"Hydroelectric Production in the New South." January 30. Attendance 61.

Missouri School of Mines and Metallurgy

Biography of Faraday, by G. L. Leisher, Student;

My Summer's Work, by M. R. James, Student. Film—"Steinmetz." January 28. Attendance 16.

University of Missouri

The Engineering Profession and the Rewards it Offers, by A. C. Lanier, head, Dept. of Elec. Eng. February 4. Attendance 28.

Montana State College

The Button Railroad, taken from *Westinghouse Magazine*, presented by M. J. Ovens, Student;

Some Technical Aspects of Sound Picture Photography, taken from Bell Laboratories Record, presented by Joseph J. Schuler, Student;

Power for Aircraft Radio, taken from *Electric Journal*, presented by M. Severud, Student. January 8. Attendance 130.

Three films presented entitled "Building New York's Newest Subway," "Hydroelectric Power Production in the New South," and "Blasting the Waterways of America." January 15. Attendance 213.

Radio Charts the Air Course, taken from *Radio News*, presented by E. J. Christiansen, Student;

Power Generation at Niagara Falls, taken from *Electric Journal*, presented by Earl Doney, Student;

Noise Measurements, taken from Electrical Engineering, presented by Frank Holly, Student;

Improving Theater Acoustics, by Joseph Hurst, Student. January 22. Attendance 131.

English for Engineers, by Paul O. Koetitz, Student;

Piezoelectric Effects, by William McKay, Student;

Vacuum Tubes Lead the Way, taken from Electrical Engineering, presented by Thomas Micka, Student. January 29. Attendance 135.

Industrial Mobilization, by Dr. Kirk, professor of chemistry. Illustrated with lantern slides. February 5. Attendance 149.

University of Nebraska

Election of officers as follows: P. Ehrenhard, chairman; W. G. Norris, vice-chairman; Walter M. Ely, secretary-treasurer. Following dinner, the students went to the Burlington Yards where Mr. Wesson, signal engineer for the C. B. & Q. Railroad, demonstrated the switching and signal system installed there. January 23. Attendance 32.

University of Nevada

Business meeting. January 7. Attendance 8.

Up-River Storage, by James Shaver, Sierra Pacific Power Co. January 14. Attendance 15.

The Operation of the Dial Telephone, by Willis Pressel, Bell Telephone Co. and senior student in Electrical Engineering. January 21. Attendance 16.

Newark College of Engineering

The Mechanical Brain, by C. H. Stephan, Student;

The Application of A. C. Rectifiers to Radio High Voltage Supplies, by A. Katz, Student. January 26. Attendance 18.

The Mercury Jet Wave Rectifier, by G. Rust, Student;

The A-C. Arc and Deion Circuit Breaker, by J. Scheid, Student;

The Earth Inductor Compass, by by C. Wayer, Student. February 9. Attendance 17.

College of the City of New York

Election of officers as follows: Charles Hachemeister, Chairman; Alex Rosenberg, vice-chairman; Howard Klein, secretary; Bernard Beaman, treasurer. January 15. Attendance 20.

New York University

Description of Apparatus and Routine in the Sherman Creek Power Plant, by J. F. Seivers, Student;

Operation of D-C. Relays, by W. J. Driver, Student;

An Acoustical Treatment of Broadcasting Studios, by M. Bogstahl, Branch Secretary;

An Original Idea in Television Scanning, by S. H. Revitz, Student;

Cables, by O. M. Lerz, Student. January 9. Attendance 17.

Business meeting. February 2. Attendance 18.

North Carolina State College

Film—"Nature's Frozen Assets." January 20. Attendance 40.

University of North Carolina

The Principle of the Three-Electrode Vacuum Tube, by Professor R. F. Stainback. Report of the Southern District Meeting at Louisville, by C. P. Hayes, Branch Representative. January 15. Attendance 33.

The Place of the Electrical Engineer in a Power Company, by P. G. Johnson, Student;

Cooperative Talk, by E. F. Frisby, Student. January 29. Attendance 29.

North Dakota State College

Film—"Conowingo." January 16. Attendance 75.

The Centennial Exposition of 1876, by F. W. Pearson, New York Life Insurance Co. Film—"Enamelware." January 28. Attendance 89.

University of North Dakota

The Effect of Lightning on Transmission Lines, by B. J. Shields, Student. Refreshments served. January 14. Attendance 20.

Election of officers as follows: B. J. Shields, chairman; Charles King, vice-chairman; Mark Scarff, secretary-treasurer. Febuary 4. Attendance 20.

Northeastern University

Construction Problems of the Fifteen-Mile Falls Development Transmission Line, by C. A. Booker, New England Power Co. Illustrated with slides. January 13. Attendance 48.

University of Notre Dame

Street Lighting and the Use of Remote Control, by Mr. Guin, South Bend Controllers Co.;

The Photoelectric Cell, by A. Petrauskas, Student;

Crosstalk and Its Elimination in Telephony, by John Perone, Student;

The Life of Ampere, by A. D. Neal, Student. Summary of news events in the electrical field was given by Patrick Murray, Student. January 12. Attendance 66.

Ohio Northern University

Automatic Train Control, by G. F. Ross, Student. January 20. Attendance 15.

Ohio State University

Synchronization of Paper Machinery, by G. E. Stoltz, Westinghouse Electric & Mfg. Company. January 15. Attendance 32.

Ohio University

A New Light-Intensity Meter, by George Wyckoff, Student;

Artificial Fever and Other Effects in the Human Body, by Herbert Adcock, Student. Film—"Arc Welding Industry." January 12. Attendance 14.

Oklahoma A. & M. College

Watt-Hour Meters, by Harold Brown, Student. January 15. Attendance 26.

University of Oklahoma

The Belle Isle Generating Station of the O. G. & E. Co., by Mr. Danner, engineer for the company. Illustrated with diagrams and slides. November 20. Attendance 51.

The Effect of Frequency Cut-Off on Sound Transmission, by Mr. Jones, Bell Telephone Co. Illustrated. January 6. Attendance 44.

Oregon State College

Business meeting. December 19. Attendance 30.

My Experiences at the Solar Observatory and Elsewhere During the Past Year, by Professor W. Weniger. January 15. Attendance 31.

Electromagnetic Light Valve and Its Application to Sound Recording, by Dale Hansen, Student;

High-Permeability Alloys, by C. Boucher, Student. February 2. Attendance 49.

University of Pittsburgh

Radio Compass, by C. W. Robinson, Student. C. H. Carroll, Student, gave a travelogue of a trip from Pittsburgh to New Orleans. December 4. Attendance 118.

A Travelogue Through China and Korea, by S. R. Staples, Westinghouse Elec. & Mfg. Co. Entertainment and refreshments followed. December 11. Attendance 76.

The History of Lighting, by D. C. Stengel, Student. E. F. Freundt, Carnegie Steel Co., reviewed power plant operation at the Homestead Steel Mill. December 18. Attendance 119.

History of the Inhabitants of Czechoslovakia, by M. Getting, Student;

Mine Laying During the World War, by O. L. Endler, Student. January 8. Attendance 111.

Two films as follows: "The Deion Breaker," and "Dynamic America." R. J. Hanna, Westinghouse Research Laboratories, demonstrated a talking motion picture projector. January 15. Attendance 85.

Modern Street Cars, by R. L. Dumeyer, Student. An explanation of the telephone typewriter was given by R. E. Morrell, Student. January 23. Attendance 114.

Pratt Institute

A discussion of the relation between education and industry was given by H. P. Miller, Instructor in Electrical Engineering. January 15. Attendance 91.

Two films presented, "New York's Newest Subway," and "Distribution of Power in the New South." January 29. Attendance 51.

Rhode Island State College

Fifteen-Mile Falls Development, by A. Galonio and J. Scussel, Students. January 19. Attendance 8.

Circuit Breakers, by L. Crandall, Student. Short business meeting followed. February 11. Attendance 13.

Rutgers University

Tendencies and Progress of Railroad Electrification in Europe Compared with American Practise, by Mr. Gelhaus, Student;

The Opportunities for Employment with the Railroads, by Mr. Jobbins, Student. December 9. Attendance 20.

Steam Generation, by Mr. Howell, Student;

Transmission and Distribution, by Mr. Trompen, Student;

The Opportunities for Employment with the Electric Light and Power Companies, by Mr. Wegel, Student. January 6. Attendance 21.

University of South Carolina

Radio Central, Rocky Point, L. I., by J. A. Kaigler, Student;

Electric Power for Cotton Mills, by H. G. Smith, Student January 12. Attendance 30.

Election of officers as follows: L. E. Rankin, chairman; C. H. Bryan, vice-chairman, L. W. Dickerson, Jr., secretary. February 9. Attendance 10.

South Dakota State School of Mines

Mr. Mitenger gave an interesting talk on his work with the Westinghouse Electric & Mfg. Co. January 22. Attendance 44.

University of Southern California

Nomination of officers. January 7. Attendance 44.

Election of officers as follows: A. E. Mathews, chairman; H. G. Cook, vice-chairman; M. C. Marshall, secretary; C. M. Drury, treasurer. January 14. Attendance 32.

A discussion of radio interference was given by A. G. Walters, Radio Trades Commission. January 21. Attendance 26.

Stanford University

Panel Type and Step-by-Step Type of Dial Telephone Systems, by W. W. Stahl, Pacific Telephone & Telegraph Co. January 15. Attendance 31.

Inspection trip through the Palo Alto exchange of the Pacific Telephone & Telegraph Co. January 17. Attendance 23.

Syracuse University

Thyratron Tubes, by Donald Robinson, Student;

Electrical Equipment in the Gypsum Industry, by Willis Kleppinger, Student. February 6. Attendance 25.

University of Tennessee

Engineering Salesmanship, by J. E. Housley, Aluminum Company of America. February 5. Attendance 18.

University of Texas

Election of officers as follows: T. E. Cole, President; C. J. Pilgrim, vice-president; J. H. Neidert, secretary-treasurer; D. Sussin, corresponding secretary. January 23. Attendance 49.

University of Vermont

Micarta Insulation, by E. V. Kibby, Student. January 13. Attendance 25.

Film—"Through the Switchboard." February 10. Attendance 33.

Virginia Polytechnic Institute

The Steinmetz that I Knew, by J. E. Birdsall, Student;

The Signal Corps Camp, by L. W. Webb, Jr., Student;

Arc Welding and Structural Steel, and, A Soundless Substation, by F. S. Boch. January 15. Attendance 31.

Business discussion. January 29. Attendance 22.

University of Virginia

G. G. Quarles, branch chairman, gave a report of the conference on Student Activities held during the Institute's Southern District meeting at Louisville, Ky. January 13. Attendance 16.

University of Washington

Film—"From Mine to Consumer." December 11. Attendance 23.

My Trip East to the Tau Beta Pi Convention, by George Palo, Student. January 8. Attendance 18.

A Year in the Frozen Arctic, by Robert J. Gleason, Student. January 15. Attendance 14.

Washington State College

Crysal Oscillators, by Lester Hatfield, Student. Duane Olney, Student, described the hydroelectric station on the Clearwater River, owned by the Pacific Power & Light Co. January 7. Attendance 24.

Washington University

L. W. Sieck, Student, gave a talk on the

St. Louis, Mo., police radio installation. January 15. Attendance 18.

West Virginia University

Business meeting. February 3. Attendance 30.

University of Wyoming

EINSTEIN'S THEORY OF RELATIVITY, by Dr. Philo F. Hammond, head of Physics Department. January 22. Attendance 37.

Yale University

TIDE WATER POWER, by H. Gears, Student;

ROCKY RIVER DEVELOPMENT OF THE CONNECTICUT LIGHT AND POWER COMPANY, by A. A. Watson, Student;

BOULDER CANYON PROJECT, by O. C. Rutledge, Student. December 9. Attendance 13.

ELECTRO-ACOUSTIC REPRODUCTION OF SOUND, by Dr. E. E. Free, Professor of General Science, N. Y. University. Joint meeting with the A. S. M. E. Branch. January 6. Attendance 66.

THE ART OF PUBLIC SPEAKING, by Professor Hubert Greaves. Illustrated. January 13. Attendance 44.

STROWGER DIAL SYSTEM, by E. Levy, Automatic Electric Company. Joint meeting with the Connecticut Section, A. I. E. E. January 16. Attendance 97.

LIGHTNING ARRESTER PROBLEMS IN DISTRIBUTION SYSTEMS, by R. Philip Hart, Cazenovia Electric & Telephone Co. January 17. Attendance 30.

A COMPREHENSIVE STUDY OF ELECTRICAL DEVELOPMENTS IN 1930, by J. N. Buckwalter, Student;

A STATISTICAL SURVEY OF ELECTRICAL INDUSTRIES IN 1930, by L. Clare, Student;

THE NATIONAL BROADCASTING NETWORK, by P. Thomson, Student;

STEEL MILLS, by R. M. Ferris, Student;

DIRECT CURRENT APPLICATION TO STEEL MILL DRIVES, by D. B. Fisk, Student;

ALTERNATING CURRENT FOR STEEL MILL DRIVES, by R. Schlitt, Student. January 20. Attendance 13.

Employment Notes

Of the Engineering Societies Employment Service

Men Available

ELECTRICAL ENGINEER, age 28; single; with considerable industrial experience; one year as graduate assistant; M. S., Iowa State College, 1930; B. S., Pennsylvania State College, 1925. Desires position as instructor, with prospect of permanent teaching position. C-3202.

ERECTING ENGINEER, 46, of broad experience in power plant construction, maintenance and operation. Exceptional ability in the erection and wiring of switchboards, power plant auxiliaries, oil circuit breakers, and high-voltage outdoor substations. Available immediately. C-8792.

HEAD OF ENGINEERING DRAWING DEPARTMENT of prominent university for seven years will consider change to similar position. Available June 1931. B. S. in electrical engineering. Telephone and electrical experience. Practical machine designer. B-8248.

1930 GRADUATE ELECTRICAL ENGINEER, University of Minnesota, age 23. Experience as a regular tester at Westinghouse Electric & Manufacturing Company. Desires position with a power company. Interested in generator or distribution work. Location, Middle West or Pacific Coast. Available now. C-8796.

ELECTRICIAN, experienced in all branches of electrical work, especially insulation application and manufacture. Capable of directing any type of electrical construction or maintenance. Considerable experience in development and application of porcelain parts. C-8769.

MECHANICAL AND ELECTRICAL ENGINEER, after thirteen years with one of the leading corporations, is now available. Experience covers all phases of design, construction, and operation of modern turbo-electric generating stations for public and private utilities, including putting existing plants in more efficient operation at moderate cost. C-8249.

GRADUATE ELECTRICAL ENGINEER, 1921. Many years' maintenance and construction work in Latin America, design and drafting experience, sound sales engineering training with G. E., fluent Spanish. Desires position along commercial or engineering lines. Preferred location, New York City or abroad. Available immediately. C-6551.

ELECTRICAL-MECHANICAL ENGINEER, married, 7 years' experience including G. E. Test, substation and distribution with utility, development with electrical manufacturer, superintendent of small shop and operation of substations and motor rooms with a steel mill. C-1063.

ELECTRICAL ENGINEER, 1930, experienced in installation, maintenance, and repair of motors as used in plants for driving industrial machinery. Have had some work on control; control of equipment for motors, on a-c. and d-c. circuits. Desires to connect with some kind of industrial equipment company. Location, immaterial. C-8763.

GRADUATE ELECTRICAL ENGINEER, 1929. One year Westinghouse Student Course. Several months' diagram and substation layout experience. Age 23, single. Location preferred, Middle West. C-8523.

ELECTRICAL ENGINEER, 1930 graduate of first-class technical school of New York State desires immediate connection. Prefers testing, research, or any other junior electrical engineering work suitable for a recent graduate. Some hydroelectric, power and lighting maintenance, construction, installation and testing before graduation. Keeping up in studies. Not interested in sales. Good references and personality. C-7936.

ELECTRICAL ENGINEER, 30, single, technical graduate, G. E. Test, ten years design and construction of substation, power plants, electrical railways and mines, five years foreign. Desires position as engineer or general foreman. Location, anywhere. Available at once. C-217.

SOUTH AMERICAN ELECTRICAL ENGINEER, 1930 graduate, 25, single. Two and one-half years' power plant experience. Desires connection with an American company. Location in any part of the States or in any Spanish speaking country. C-8766.

GRADUATE ELECTRICAL ENGINEER, 1928, single, age 25. Aggregate of two years in public utility and railway operating companies. Year Student Course, and two years railway and material handling application engineering with large manufacturer. Desires position with railway, utility, manufacturer or consulting firm. C-8671.

ELECTRICAL ENGINEER, university graduate, 44, married. Two years G. E. Test, 16 years' experience in design and manufacture of transformers with large companies. Desires position with utility or manufacturing company. Best of references. Available on short notice. C-8806.

ELECTRICAL ENGINEER, age 42. Have twenty years' experience in public utility business design, construction and operation. Also some industrial experience. With last employer twenty years. Location, immaterial. C-8798.

ELECTRICAL ENGINEER, college graduate, 31, married. Eleven years in station, transmission and distribution designs; system operation and planning; superintendence of meter and relay department; studies; reports and calculations. Good theoretical as well as practical background. Accustomed to responsibilities. Prefer New York or environs but will consider good proposition elsewhere. B-9401.

ELECTRICAL ENGINEER, graduate Sheffield Scientific School, 23 years' experience including: electrical contracting with companies doing large power work; five years in service department of large electrical manufacturing company as field engineer and supervisor. Experienced electrical estimator. Desires permanent connection, preferably in the East. C-3175.

INDUSTRIAL ENGINEER, electrical graduate, with additional study at M. I. T. Three years' manufacture and electrical test. Considerable electrical and mechanical experience relative to application of power equipment in industrial plants. Fifteen years' experience including seven years with electric utilities. Available upon short notice. Location, anywhere. A-4018.

PHYSICIST Ph. D., 39 years old, with 12 years' experience in electrical development, formerly chief of a physical laboratory, familiar with U. S. A. and foreign patent laws, desires position in electrical concern, preferably television or movietone laboratory. C-8604.

GRADUATE ELECTRICAL ENGINEER, 29, married. Two years' experience on industrial plant layout. 1½ years supervising construction jobs and one year system planning, eastern utility. Desires position where extensive accounting knowledge, acquired through night studies is an asset. Best references. Location preferred, Metropolitan New York. Available immediately. C-8535.

COLLEGE GRADUATE, 25, single, B. S. degree in E. E. Seven months R. C. A. engineering course, 11 months N. B. C. engineering course. Experience in development and research work. Seeking position in any electrical line with future and opportunity for advancement. C-8457.

ELECTRICAL ENGINEER, S. B. degree in in E. E. in 1925. Five years' experience in electrical equipment design, public utility operation and field construction. Natural writing talent. Desires work in editorial or related fields. C-4875.

WEST COAST REPRESENTATION—ELECTRICAL ENGINEER with successful selling experience, wishing to locate in Southern California, offers his services to manufacturers of products requiring a representative with engineering background. At present employed in New York City. C-1074.

WIRING DIAGRAM SPECIALIST, desires position with public utility; 43, married, technical education. Understands cooperation necessary between office and field forces in connection with wirings. Familiar with power-house and substation layouts, conduit plans, bus structures, switchboards. Experienced in drafting and its application to field work. Location preferred, East or South. C-8436.

ELECTRICAL DESIGNING ENGINEER, technical graduate, 33, expert draftsman. Power-plant, substation and illumination design experience. Two years' experience on mercury arc rectifier substations for railway service. Seeking permanent position with progressive concern. B-7332.

GRADUATE ELECTRICAL ENGINEER, single, 33. Six years with large manufacturing corporation. Experienced in manual and automatic switchgear application, preparation of specifications, testing and electrical drafting. Location, United States America. Available immediately. C-8680.

GRADUATE ELECTRICAL ENGINEER, 31, single, eight years' experience, design and construction of transmission lines, voltages up to, and including 220-kv., outdoor and indoor high-voltage substation and distribution networks. Desires position in engineering or construction department of large utility or holding company. Location, immaterial. C-3564.

ELECTRICAL DRAFTSMAN, 29, single but with dependents. Experienced on substation and power-house design, industrial and marine equipment installation. Desires temporary or permanent position. Available at at once. Location preferred, Pacific Coast. C-8729-311-C-7.

PRODUCTION MANAGER, age 49, married. Mechanical and electrical graduate. Experienced executive and organizer. Eighteen years' experience in production, maintenance, plant layout, budgeting, estimating and time study in large machinery and copper wire field. Desires a position that requires energy and initiative. Available immediately. Location preferred, immaterial. C-4440.

ELECTRICAL ENGINEER has had 8 years' experience with vacuum tube applications. Experience has covered research and development of precision laboratory apparatus. Recent activities have been centered on audio-frequency transmission circuits and design of high quality amplifiers. Inquiries invited from leading companies requiring such services with location preferably in New York. C-8745.

RAILROAD-TELEPHONE MAN, 42, married. Six years' railroad experience, 25 years' telephone experience. Desires position as foreman. Qualified to engineer layout of circuits for construction, maintenance, installation of printers, pneumatic tubes, other communication auxiliaries. Able to do Western Union Telegraph contact work, prepare close estimates and handle men. Can furnish references. C-7753.

GRADUATE ELECTRICAL ENGINEER, 28, married, American, wishes position in experimental, research or development work. Three years' experience in inspection and small instruments. Two years in accounting and statistics. B-8815.

ENGINEER, B. S. Harvard; B. S. Massachusetts Institute of Technology, mechanical and electrical engineering. Three years instructor in physics and electrical engineering. Three years drafting and design. Three and one-half years radio research and development, last two and one-half years being with R. C. A. Victor Company (Massachusetts). C-4275.

INDUSTRIAL ELECTRICAL ENGINEER, 43, over 15 years' experience on industrial plants, distribution, special applications; design, specifications, construction and maintenance. Also fire prevention and protection engineering. C-8414.

ELECTRICAL ENGINEER, 35, technical education with 10 years' executive experience supervising both design and construction. Desires position as engineer in charge of design or construction, or plant engineer. Location, immaterial. C-8683.

ELECTRICAL DESIGN DRAFTSMAN OR CHECKER, 31, single. Third year night engineering, twelve years' experience covering design of power plants, substations and network systems. Desires connection with public utility or engineering firm. Location, immaterial. Available on two weeks' notice. B-8628.

GRADUATE ELECTRICAL ENGINEER, age 25, single. Reared in the Orient, traveled widely. One year test course with motor manufacturer, one year sales experience on Pacific Coast. Desires permanent location with a company looking forward to an expansion in its foreign business. Available at once. Location, anywhere in U. S. B-6945-311-C-5-San Francisco.

MANAGER OR SUPERINTENDENT, ag 47, married. Executive, electrical or industrial. Successful organizer, efficient operator. Knows men and can handle them. Especially interested properties not now paying, where future depends on results. Reads, writes, and speaks Spanish. Capable earning six thousand up. Available, reasonly short notice. Location, preferred, not particular (Western U. S. preferred)." C-8777-312-C-1-San Francisco.

TECHNICAL GRADUATE in electrical engineering, 29, single, 1½ years' G. E. Test; over 10 years' experience with leading electrical company in repair and testing of electrical apparatus. Desires position in testing and experimental work on motors, generators, etc. Future prospects considered more important than initial salary. Best of references. C-8778.

1930 GRADUATE, ELECTRICAL ENGINEERING, 22, single. Seven months Westinghouse test. Desires position in operating or service department of utility company, but will consider work of any kind. References. Location, West or Middle west. Available at once. C-8779.

ELECTRICAL ENGINEER, 25, single. E. E. and Master's degrees. Good mathematician with theoretical and research grounding. General Electric test and general engineering courses. Interested in pure engineering, mathematics and teaching. Best references. Will consider any location. C-8382.

GRADUATE ELECTRICAL ENGINEER, 35, good technical school. Ten years' experience in electrical station construction and design drafting, including considerable mechanical experience. Latest position superintendent of design and construction of transformer substation. Preferring station design and construction with ability would consider engineering industrial plant maintenance or operation. C-8785.

ENGINEER, specially qualified in industrial construction or management in Spanish America. Twenty years' experience, design, construction, management, sales, more than two-thirds in United States. Unusually fluent, correct Spanish. Large acquaintance officials, industry, South America, especially West Coast.

ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco
N. D. Cook, Manager

205 West Wacker Drive
Chicago
A. K. Krauser, Manager

31 West 39th St.
New York
W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

Men Available.—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

Opportunities.—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

Voluntary Contributions.—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

Answers to Announcements.—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

Would take a contract, branch managership, or sales agency part commission basis, any engineering line, states or abroad. C-8822.

SWITCHBOARD FOREMAN, age 31, married, four years with Western Electric Company. Six years with construction companies for public utilities, specializing in installation of switchboards and control apparatus for power houses and substations. Also experience in metallic telephone and carrier current telephone installation. C-4831.

ELECTRICAL ENGINEER, 27, single. Experience with public utility company in transmission, distribution (overhead and underground), and substation design and construction. Two years design on motor installations and power-plant equipment with nationally known engineering corporation. Desires connection with engineering department of public utility company in West or Middle West. C-8541.

ELECTRICAL ENGINEER, 24, single. B. S. in E. E. Westinghouse graduate student course. Twenty-one months' experience, design and application of railway control apparatus. Also some experience as student engineer, large power company. Desires position with opportunity for advancement with railway operating company, other utility, manufacturing company. Location preferred, East, Middle West. C-8742.

ELECTRICAL ENGINEER, B. S. degree in 1919; age 33, married. Ten years' experience with large company making electrical power apparatus, includes designing of electrical and mechanical construction and calculating of cost, weight and dimensions, in connection with customers' negotiations. Available at once. Location, immaterial. C-4633.

ELECTRICAL ENGINEER, 24, married. Desires engineering work. Has had experience with oscillographs and radio. Holds second-grade commercial wireless operators license. Has public utility test experience. Also surveying experience. Personal interview desired. C-8035.

GRADUATE ELECTRICAL ENGINEER, 30, married. Practical experience in design and construction of industrial equipment and lighting layouts; electric overhead and underground distribution with traction utility; electric and general contracting in own business. Available immediately. B-6384.

GRADUATE ELECTRICAL ENGINEER, 28, four years' manufacturing experience in production and engineering on electrical motors, desires position with company where greater opportunities are offered. C-2882.

Membership

Transfers Recommended

The Board of Examiners, at its meeting of February 18, 1931, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the National Secretary.

To Grad of Fellow

CHURCHWARD, ALEXANDER, Technical Director, Wilson Welder & Metals Co., North Bergen, N. J.

HARRISON, WILLIAM H., plant engineer, American Tel. & Tel. Co., New York.

JOHNSON, F. ELLIS, head of Dept. of Elec. Engg., Iowa State College, Ames, Iowa.

MELVIN, HOWARD L., assistant electrical Engr., Electric Bond & Share Co., New York.

SILLCOX, LEWIS K., vice-president, New York Air Brake Co., Watertown, N. Y.

To Grad of Member

ABBOTT, THOMAS A., instructor in Elec. Engg., Yale University, New Haven, Conn.

AYRES, EDMUND D., Asst. Prof. of Elec. Engg., University of Wisconsin, Madison, Wis.

BRAATEN, THEODORE, Switchgear Engineer, Westinghouse Elec. & Mfg. Co., Boston, Mass.

BROWN, JOSEPH S., engineer, Stone & Webster Engg. Corp., Boston, Mass.

BURTON, JAMES A., telephone & telegraph engr., American Tel. & Tel. Co., New York.

COWGILL, LESTER B., asst. engr., Electric Bond & Share Co., New York.

FARRINGTON, JOHN F., radio engr., International Communications Labs., New York.

HAGAN, JAMES S., elec. engr., Central Railroad Co. of New Jersey, Jersey City Terminal, N. J.

HENDRICKS, CHESTER I., Plant Engr., Texas Electric Service Co., Fort Worth, Texas.

HUTTON, LESLIE B., chief engr., Southland Electric Power Board, Invercargill, N. Z.

JORDON, CHARLES A., asst. engr., Electric Bond & Share Co., New York.

PIERCE, ROBERT E., asst. engr., Electric Bond & Share Co., New York.

SCHWAGER, A. C., oil circuit breaker design engr., Pacific Electric Mfg. Corp., San Francisco, Calif.

SQUIRES, HOWARD A., district manager, Delta-Star Electric Co., and Champion Switch Co., Boston, Mass.

VAN DYCK, WILLIAM VAN BERGEN, manager, International General Electric Co. Inc., Schenectady, N. Y.

WRIGHT, ERNEST M., asst. engr., Pacific Gas & Elec. Co., San Francisco, Calif.

◆

Applications for Election

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before March 31, 1931.

Abeel, L. B., Tonawanda Power Co., North Tonawanda, N. Y.

Amick, W. M., Western Electric Co., Inc., Newark, N. J.

Anderson, E. G., General Electric Co., Fort Wayne, Ind.

Babbitt, G. W., Canadian & General Finance Co., Toronto, Ont., Can.

Bairos, C. A., Stanford University, Stanford University, Calif.

Barnett, F. G. (Member), Rockford Electric Co., Rockford, Ill.

Becker, A. J., Allis-Chalmers Mfg. Co., Pittsburgh, Pa.

Berlin, J. A. W., International Harvester Co., Chicago, Ill.

Blocksom, F. C., United States Bureau of Mines, Denver, Colo.

Boicourt, F. R., Iowa Public Service Co., Storm Lake, Iowa

Breece, C. A., Indiana Bell Tel. Co., Indianapolis, Ind.

Butler, J. W., General Electric Co., Schenectady, N. Y.

Campbell, G. H., General Electric Co., New York, N. Y.

Clutts, C. E., American Tel. & Tel. Co., New York, N. Y.

Cole, C. S., Copper & Brass Research Association, New York, N. Y.

Compton, K. T., (Fellow), Mass. Inst. of Technology, Cambridge, Mass.

Crary, S. B., Jr., General Electric Co., Schenectady, N. Y.

Cyr, A. J., New Brunswick Electric Power Comm., St. John, N. B., Can.

David, A. R., Brooklyn Edison Co., Brooklyn, N. Y.

Deavers, W. R., Virginia Electric & Power Co., Richmond, Va.

Diaz, M. S., Allis-Chalmers Mfg. Co., West Allis, Wis.

Dorman, B. H., General Electric Co., Buffalo, N. Y.

Elder, T. W., The Ohio Power Co., Coshocton, Ohio

Erskine, S. E., Canadian General Electric Co., Vancouver, B. C., Can.

Fife, W. H., United Electric Light & Power Co., New York, N. Y.

Foos, C. B., General Electric Co., Schenectady, N. Y.

Fountain, L. L., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Franzen, J. E., Management Engg. Corp., Indianapolis, Ind.

Geer, A. L., Shell Pipe Line Corp., Colorado, Tex.

Gosinski, J. N., Allied Engineers, Inc., Jackson, Mich.

Goslin, R. A., Fairbanks-Morse & Co., Indianapolis, Ind.

Haege, O. C., E. J. Cheney, New York, N. Y.

Hamner, F. G., Allied Engineers, Inc., Birmingham, Ala.

Hansen, P., Western Union Telegraph Co., New York, N. Y.

Haynes, H. H., 59 Hilltop Drive, Nichols, Bridgeport, Conn.

Heiser, C. A., Anaconda Wire & Cable Co., Dallas, Tex.

Henderson, F. M., Indiana & Michigan Electric Co., South Bend, Ind.

Herrington, L. B., Kentucky Utilities Co., Louisville, Ky.

Hitchcock, R. C., (Member), Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Hively, J. P. H., General Electric Co., Schenectady, N. Y.

Holper, P. E., Western Electric Co., Kearny, N. J.

Holzman, W. H., 245-29th St., Oakland, Calif.

Horan, T. I., Pennsylvania Power & Light Co., Danvill , Pa.

Hutcheson, R. M., Virginia Electric & Power Co., Richmond, Va.

Engineering Literature

New Books

In the Societies Library

AMONG the new books received at the Engineering Societies Library, New York, during January are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

INDUSTRIAL HISTORY OF THE UNITED STATES. By Witt Bowden. N. Y., Adelphi Company, 1930. 511 pp., 8 x 6 in., cloth. $4.00.——A very readable one-volume account of our industrial growth from the period of discovery to the present day. The economic forces governing each epoch are clearly indicated and their influence upon our industrial development shown. The general reader as well as the student will find the book of interest.

TELEPHONE THEORY AND PRACTICE, v. 1; Theory and Elements. By Kempster B. Miller. N. Y., McGraw-Hill Book Co., 1930. 486 pp., illus., diagrs., 9 x 6 in., cloth. $5.00.——This is the first volume of a three-volume text which is intended to give students and advanced workers a comprehensive review of modern telephony. The book is the successor of the author's "American Telephone Practice," but is entirely new.

The present volume relates to the underlying theory. An introductory general and historical section is followed by a discussion of acoustical and electrical principles. The elements of telephone apparatus are then treated. The work is non-mathematical and descriptive.

AMBER TO AMPERES; the Story of Electricity. By Ernest Greenwood. N. Y., Harper & Bros., 1931. 332 pp., illus., ports., 10 x 6 in., cloth. $4.00.——Sketches the growth of our knowledge and use of electricity from the earliest times to the present day. The author's method has been to select the principal events in the progress of the science and to present an account of the social and historical background of each and of the chief personalities involved. The uses of electricity for illumination and communication are emphasized in this interesting work.

Drehstrommotoren mit Doppelkäfiganker und Verwandte Konstruktionen. By Franklin Punga and Otto Raydt. Berlin, Julius Springer, 1931. 165 pp., illus., diagrs., 9 x 6 in., bound. 16.-r. m.——Discusses the design and construction of these motors, explains their advantages and describes the more important commercial types. A section is devoted also to centrifugal couplings.

The Dynamic Universe. By James Mackaye. N. Y., Charles Scribner's Sons, 1931. 308 pp., 8 x 6 in., cloth. $3.50.——This book presents a radiational theory of the structure of matter and the cause of its change of motion. The theory is physical, rather than mathematical or metaphysical. It aims, while accepting Einstein's equations, to give an explanation and reinterpretation of them which will be more natural. An important contribution to theoretical physics.

An Early Experiment in Industrial Organization; being a history of the firm of Boulton & Watt, 1775-1805. By Erich Roll. Lond. & N. Y., Longmans, Green & Co., 1930. 320 pp., plate, 9 x 6 in., cloth. $5.00——An interesting study of the organization of the earliest engineering factory, and of the business methods adopted in its management. The rapid development of the business is traced in detail, and its business organization and policy, wage system, relations with labor, and similar problems are discussed. The point of view is entirely economic.

Electrical Equipment. By T. C. Lloyd. N. Y., John Wiley & Sons, 1930. 287 pp., illus., diagrs., tables, 9 x 6 in., cloth. $3.50.——Intended for students of mining, mechanical and chemical engineering who have studied the theory of the motor, generator, and transformer, and wish a brief account of the theory of a wider variety of electrical equipment, as a guide to the selection of apparatus for given requirements. In addition to the fundamental machines, the author discusses switchboards, meters, storage batteries, illumination, heating, transmission, distribution, and rectification. Comparative cost data are given, and economic questions discussed.

Electroplating; a Survey of Modern Practise. By Samuel Field and A. Dudley Weill. N. Y., Isaac Pitman & Sons, 1930. 205 pp., illus., tables, 8 x 5 in., cloth. $2.00.——A concise treatise which brings together the results of modern research for the practical electroplater.

Guide du Technicien pour l'Organisation du Travail Personnel. By J. Rousset. Paris, Ch. Béranger, 1930. 192 pp., illus., 10 x 6 in., cloth. 62,50 fr.——This unusual book is a guide to the collection and utilization of information, for the benefit of engineers. The author discusses the collection and classification of notes and documents, the organization of libraries, the use of reference libraries, the writing of articles, book publishing and a number of related topics. Much practical, sound advice not collected elsewhere is given.

Magnetic Phenomena. By Samuel Robinson Williams. N. Y., McGraw-Hill Book Co., 1931. (International Series in Physics). 230 pp., illus., diagrs., tables, 9 x 6 in., cloth. $3.00.——A general survey of the whole field, intended to stimulate interest in research work in magnetism and to give the preparatory background for it. The theory of magnetism and the effects of magnetism upon the mechanical, acoustical, electrical, thermal and optical properties of matter are presented.

The Quantam Theory. By Fritz Reiche; translated by H. S. Hatfield and Henry L. Brose. N. Y., E. P. Dutton & Co., 1930. 218 pp., 8 x 5 in., cloth. $2.10.——An excellent account of the origin and development of the quantum theory from its introduction to the present day, which does not make any great mathematical demands upon the reader. A bibliography and numerous references furnish ample guidance to students who wish to pursue the subject further.

Relaisbuch. By Vereinigung der Elektrizitätswerke. Berlin, The Association, 1930. 457 pp., illus., diagrs., plates, 8 x 6 in., cloth. Price not indicated.——A handbook for operators in electric power stations and electrically equipped industrial plants, upon the practical use of protective relays. The protective systems in use, their application under various conditions, the accessories of relay systems, and the methods of testing relays are discussed fully and practically. The book is published by the Association of Electric Plants of Germany.

Richtlinien für Geschweisste Gasrohrleitungen von mehr als 200 mm Durchmesser und mehr als 1 atü Betriebsdruck. Berlin, V. D. I. Verlag 1930. 10 pp., 8 x 6 in., paper. Price not indicated.——Specifications for welding gas mains, approved by the Standards Committee of the Society of German Engineers.

Die Röntgentechnik in der Materialprüfung. By J. Eggert and E. Schiebold. (Ergebnisse der technischen Röntgenkunde, bd. 1). Leipzig, Akademische Verlagsgesellschaft, 1930. 206 pp., illus., diagrs., 9 x 6 in., cloth. 16,80 r. m.——Contains a course of lectures delivered by various specialists at the Charlottenburg Technical High School. These describe the principles of Roentgenology, the apparatus and methods used, and the ways in which X-rays are used to detect flaws in castings and welds, in chemical engineering, and in other branches of manufacturing. Much practical information is given.

Text-Book of Practical Physical Chemistry. By K. Fajans and J. Wüst. N. Y., E. P. Dutton & Co., 1930. 233 pp., illus., 9 x 6 in., cloth. $4.95.——A laboratory textbook, giving detailed directions for performing experiments that illustrate the chief methods of physicochemical investigation. The theory of each experiment is also explained.

Treatise on Physical Chemistry. Edited by Hugh S. Taylor. 2nd edition. N. Y., D. Van Nostrand Company, 1931. 2 v., illus., diagrs., tables, 9 x 6 in., fabrikoid. $15.00 (2 v.).——Intended to present modern physical chemistry with sufficient comprehensiveness to meet the needs of advanced students and of men engaged in industrial research who wish the theoretical treatment of their investigations. The work is the joint effort of a group of eminent authorities and is a most satisfactory treatise.

The new edition has been extensively revised to include recent developments.

Verdampfen Kondensieren und Kühlen. By E. Hausbrand. 7th edition revised by M. Hirsch. Berlin, Julius Springer, 1931. 359 pp., illus., diagrs., 9 x 6 in., cloth. 29.-r. m.——Although issued as a new edition of Hausbrand's well-known work, this is practically a new book. To a larger extent than formerly, the theoretical principles are presented. Formulas and graphs replace many tables of numerical data. The technique of evaporating has been made the principal topic, and condensing and cooling are considered only in relation to evaporating plants.

The new work treats the subject much more systematically and scientifically. The data required by the designer are given extensive discussion, and the construction and use of evaporating apparatus are treated.

Vollständige Zahlentafel und Diagramme für das Spezifische Volumen des Wasserdampfes bei Drücken zwischen 1 und 270 at. By H. Speyerer and G. Sauer. Berlin, V. D. I. Verlag, 1930. 8 pp., 8 x 12 in., paper. 2,50 r. m.——These tables are based on the data of Knoblauch, Raisch, Hausen, Davis and Smith. The tables extend from 100 deg. cent. to 550 deg., by ten-degree intervals. Values are given for each atmosphere below 120, and for each five atmospheres for higher pressures.

Engineering Societies Library

29 West 39th Street, New York, N. Y.

Maintained as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

Selected Items *From* Engineering Index Service

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 1,800 technical periodicals are given in the following columns.

All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page or make translations of foreign articles at cost.

Accidents

ELECTRIC. Electric Shock: Interpretation of Field Notes, W. Maclachlan. *Hydro-Electric Power Commission of Ontario—Bul.*, vol. 17, no. 11, Nov. 1930, pp. 418-427, 2 figs. Analysis, of reports of approximately 700 cases of electric accidents.

Arcs

ELECTRIC. Some Causes for Variations in the Light and Steadiness of High Intensity Carbons, D. B. Joy and A. C. Downes. *Soc. Motion Picture Engrs.—Jl.*, vol 16, no. 1, Jan. 1931, pp. 61-65 and (discussion) 65-66, 3 figs. Arc length-arc voltage relations of high intensity arc depend very largely upon relative positions of positive and negative carbons; there is very definite point at which light is maximum and point of maximum light is not point of maximum steadiness. Bibliography.

Busbars

LOSSES. The Efficient Utilization of Conductor Material in Busbar Sections, O. Dannatt and S. W. Redfearn. *World Power* (*Lond.*), vol. 14, nos. 83 and 84, Nov. 1930, pp. 397-400 and Dec., pp 492-496, 8 figs. Nov.: Main factors determining conductor losses in a.c. busbar systems and influence of their distribution on temperature rises obtained; extent to which theoretical solutions are available for predetermination of temperature rise. Dec.: Experimental methods for measurement of total loss.

Cables

DESTRUCTION BY INSECTS. Beetle Damage to Lead Cable, E. J. P. Rendell. *Elec. Light and Power*, vol. 8, no. 12, Dec. 1930, pp. 70, 72 and 74, 5 figs. Cases of damage to aerial telephone cables by lead boring insects have been reported from varied parts of world; matters have been investigated by Government scientists whose findings are set forth in bulletin No. 1107 issued by Department of Agriculture; experiments of Pernambuco are related. Abstract of paper in Proc. of Entomological Soc. of Washington.

FUSE BOXES. Network Boxes. *Engineer* (*Lond.*), vol. 150, no. 3908, Dec. 5, 1930, p. 622, 1 fig. New type of link or fuse disconnecting box for four or five-core cables put on market by British Insulated Cables, Ltd.; all current-carrying parts are made from high-conductivity copper strip, and number of joints or contacts has been reduced to minimum; links are of plug type, with volted contacts.

GROUNDS. Freak Earth Faults, H. Joseph. *Elec. Times* (*Lond.*), vol. 78, no. 2042, Dec. 11, 1930, p. 1019, 3 figs. Analysis of potential differences which even may lead to shock set up in ground near grounded conductor of underground cable.

IMPREGNATING MATERIALS. Weatherproof Impregnated braided Insulation of Electric Lines (Wetterfest getraenkte Beflechtungen von elektrischen Leitungen), E. Kindscher. *Gummi-Zeitung* (*Berlin*), vol. 45, no. 9, Nov. 12, 1930, pp. 333-336. Laufenberg and others have shown increasing water impermeability of films with increasing content of organically bound lead; author's tests in Government experimental station in Berlin-Dahlem to ascertain cause of varying behavior of red-lead linseed-oil mixtures; necessity is shown of careful selection of specially suitable red lead for impregnated cables, such as will improve action of linseed oil by formation of organic lead compounds.

TELEGRAPH, TRANSATLANTIC. Advances in Transoceanic Cable Technique, H. Mason. *Inst. Radio Engrs.—Proc.*, vol. 18, no. 12, Dec. 1930, pp. 2176-2191, 3 figs. Progress in construction of transatlantic cables is described from earliest to most recent type, which operates at 1400 letters per min. without technical detail development of cable operating mechanisms is sketched indicating improvement which resulted from use of relays, magnifiers, and regenerators; application to cable art of land-line multiplex telegraph practice is shown.

TESTING. Portable Kenetron Housing Design, C. W. Evans. *Elec. World*, vol. 96, no. 26, Dec. 27, 1930, pp. 1178, 1 fig. Design is for 100-kv. cable testing set and it contains every facility for rapid routine testing; frame work is 2 by 4-in. scantling and roof and sides are of shiplap; floor is of 1 by 8-in. boards, and frame is assembled with bolts and screws.

PAPER INSULATED. Reduces Cable Ionization by Super-Vacuum Process, S. J. Rosch and H. G. Burd. *Elec. World*, vol. 96, no. 25, Dec. 20, 1930, pp., 1132-1135, 7 figs. For one year process has been used at Hastings-on-Hudson plant of Anaconda Wire & Cable Co., that has been particularly effective in removing occluded gases and moisture from compound and paper insulation before it is impregnated in preventing contamination between steps in process, with result that very low power factor is obtained even at high unit stresses.

RADIO INTERFERENCE. Simultaneous Atmospheric and Cable Interference (Gleichzeitige Luft-und Kabelstoerungen), M. Baeumler. *Elektrische Nachrichten-Technik* (*Berlin*), vol. 7, no. 8, Aug. 1930, pp. 325-330, 15 figs. Report on measurements by Haak and O. Fuchs on simple wire Emden-Vigo cable in order to study simultaneous occurrence of interference in cable and in ether.

SUBMARINE INSULATION. Paragutta, A New Insulating Material for Submarine Cables, A. R. Kemp. *Franklin Inst.—Jl.*, vol. 211, no. 1, Jan. 1931, pp. 37-57, 9 figs. Extended study was undertaken of causes of losses and other electrical weaknesses of submarine insulation and search has been made for better materials; as result of this investigation insulation called paragutta has been developed which as name suggests is derived essentially from rubber and gutta percha. Bibliography.

Circuit Breakers

OIL. Modern Switchgear. *Engineer* (*Lond.*) vol. 150, no. 3910, Dec. 19, 1930, pp. 674-675, 7 figs. Type RM circuit breaker rated at 4000 amperes at 12,000 volts with breaking capacity of 1,000,000 kva, this being, it is said, largest horizontal draw-out metal-clad switchgear unit that has been built; special feature of new Reyrolle type is complete separation of phases in circuit-breaker portion of gear.

Commutators

FAILURE. Oil Seepage Causes Commutator Failures, W. O. Hurlburt. *Elec. West*, vol. 66, no. 1, Jan. 1, 1931, pp. 24-25, 3 figs. Systematic recording and observation of commutator failures has led to conclusion that in majority of cases, primary cause of breakdowns can be attributed to seepage of oil from bearings; most records were made from motors in elevator service subjected to rotation reversal, although unidirectional machines showed identical tendencies.

Condensers

SYNCHRONOUS. Synchronous Condensers and Capacitors. *Power Plant Eng.*, vol. 35, no. 1, Jan. 1, 1931, pp. 93-94, 4 figs. Correction of low power factor by means of synchronous or static condensers.

Conductors

ELECTRIC. Control Contacts and Arc Lengths, W. B. Kindy. *Elec. Jl.*, vol. 27, no. 12, Dec. 1930, pp. 727-728, 2 figs. Characteristics of arc which is drawn when low capacity, low-voltage, d.c. circuit is opened by set of contacts in design of control circuits of modern automatic and remotely controlled electrical equipment, are discussed.

ALUMINUM. The Jointing of Steel Cored Aluminum Conductors. *Engineer* (*Lond.*), vol. 150, no. 3910, Dec 19, 1930, p. 688. Tests have been made at Prescot Works of British Insulated Cables, Ltd., on firm's patented aerial cable union, and tests show that this type of joint complies fully with requirements.

INSULATION. Ueber die Beflechtung isolierter Leitungen (Braiding of Insulated Wire) K. Sieber. *V. D. I. Zeit.*, vol. 74, no. 51, Dec. 20, 1930, pp. 1735-1738, 7 figs. Influence of thickness of braid and of braiding angle on quality and costs of braiding: mathematical analysis of braid thickness, braiding costs, etc.

LIQUID. New Experiment for Demonstrating the "Pinch" Effect (Ein neuer Versuch zur Demonstration des "Pinch" Effektes), E. Blaich. *Elektrotechnik und Maschinenbau* (*Vienna*), vol. 48, no. 49, Dec. 7, 1930, pp. 1083-1085, 4 figs. Experiment which shows that motions in liquid conductors, as noticed for instance in induction furnace, find their principal cause in electromagnetic processes.

Control

REGENERATIVE. Regenerative Control with Compound Motors on Paris Tramways, M. Bacqueyrisse. *Tramway and Ry. World.* (*Lond.*), vol. 68, no. 24, Nov. 13, 1930, pp. 275-281 and (discussion) 281-283, 11 figs.; see also editorial comment on p. 274. Design principles, simplification and improvements of regenerative control equipment; permanent coupling of motors; abolition of series-parallel transition; arrangement of motors in series; controller of reduced size; traction equipment with compound motors built by Alsthom Company, for "L" type cars on Paris street railroad two and three-car trains. Paper read before International Tramways and Light Rys. Union, Paris.

Regenerative Control with Compound Wound Motors (Stromrueckgewunnung mit Verbundmotoren), W. Mattersdorff. *Verkehrstechnik* (*Berlin*), no. 50, Dec. 12, 1930, pp. 657-660, 3 figs. Results obtained at Session of Internationaler Strassenbahn and Kleinbahnverein, October 1930, in Paris with respect to problem; various systems of regenerative control; Bacqueyrisse connection.

Controllers

ELECTRIC. Electrical Control Gear. *Engineer* (*Lond.*), vol. 150, no. 3911, Dec 26, 1930, pp. 714-715, 4 figs. Control gear made by Laurence, Scott, and Electromotors, Ltd. for machines intended for balancing large turbine rotors weighing 17 tons or more; gear of this type has been supplied to Royal dockyards and to several private shipyards.

Converters

FREQUENCY. Frequency Converters for A. C. Railroad Electrification, L. G. Smith. *Nat. Elec. Light Assn.—Bul.* vol. 17, no. 12, Dec. 1930, pp. 755-757, 6 figs. How to meet problem of single phase electrification; types of converters available; factors to consider in selection; design features of single phase generators; types of phase balances available; comparative costs and losses.

Cranes

ELECTRIC. Repulsion Motor as Crane Motor (Der staendergespeiste Einphasenkommutatormotor (Repulsionsmotor) als Kranmotor), R. Richter. *Foerdertechnik und Frachtverkehr* (*Wittenberg*), vol. 23, no. 23 and 26, Nov. 7, 1930, pp. 439-443, and Dec. 19, pp. 494-497, 6 figs. Nov. 7: Tests made on portal crane which has four repulsion motors, for hoisting, slewing, crane travel on portal and portal travel, show that for alternating current, these motors are well suited as crane motors; description of crane and result of tests with hoisting motor; Dec. 19: Result of tests with slewing and travel motors; operation characteristics and construction of one phase repulsion motors.

Diesel-Electric Plants

Practical Building Pointers for Diesel Engine Plants. *Diesel Power*, vol. 8, no. 12, Dec. 1930, pp. 632-634, 2 figs. Plan of plant designed to avoid wasting building volume on accessories.

COSTS. Operating Cost of Diesel Engine (Sul costo di esercizio dei motori Diesel), G. Colajanni. *Energia Elettrica* (*Milan*), vol. 7, no. 10, Oct. 1930, pp. 864-866. Review of relative importance of various items of operating expenses based on Italian experiences.

GREAT BRITAIN. An Oil-Engined Central Station. *Power Engr.* (*Lond.*), vol. 25, no. 297, Dec. 1930, pp. 461-465, 8 figs. Layout and constructional features of Dunoon electricity undertaking; main engines supplied by Davey Paxman & Co., Ltd.; 5-cylinder sets developing 345 b. hp. at 300 r. p. m.; vertical 4-stroke cold-starting Diesel engine with patent spring-injection systems for fuel admission; cooling water system and auxiliary plant; electrical system.

SLATER, MO. High Cost of Smoke and Cinders Cut by Slater, Mo., Diesels, R. R. Howard. *Diesel Power*, vol. 8, no. 12, Dec. 1930, pp. 618-620, 3 figs. Plant equipped with five totalling 1500 hp., each complete with engine, alternator, exciter, and switchboard panel with voltmeter, ammeters, indicating kilowatt meter and totalizing kilowatt-hour meter.

WEST VIRGINIA. Diesel Plant Generates Power for Price Hill, J. H. Edwards. *Coal Age*, vol. 35, no. 11, Nov. 1930, pp. 654 and 664, 5 figs. on 654. Largest Diesel installation in United States erected to furnish power exclusively for coal mining, in Raleigh County, W. Va.; four 360-hp. vertical engines, each direct-connected to 300-kva. 2400-volt generator, all in building 40 by 60 ft.

Electric Drive

CARGO HANDLING. Alternating Current Gaining for Materials Handling Drives, J. W. Speer. *Matls. Handling and Distribution*, vol. 5, no. 4, Jan. 1931, pp. 53-54, 3 figs. Disadvantages of induction motor; application of a.c. types especially to ore-handling equipment.

IRON AND STEEL PLANTS. Electrical Developments in the Iron and Steel Industry for 1930, D. W. Dean. *Rolling Mill Jl.*, vol. 4, no. 12, Dec. 1930, pp. 651-656, 5 figs. Discussion of extensive application of electrical equipment to rolling-mill drives, their auxiliaries and related steel-mill equipment; total horsepower applied to main drive motors for year ending December 1, 1930 was 151,540 as compared with 139,350 for preceding year.

Electric Equipment

DESIGN. Electric Field Records Notable Progress. *Power*, vol. 73, no. 1, Jan. 6, 1931, pp. 27-29, 5 figs. Turbine-driven 200,000-kva. generators to operate at 1800 r. p. m.; first hydrogen-cooled generator goes into operation; field for outdoor type of machines widened; mercury-arc rectifier applications increase rapidly new system of motor control.

FLASHOVER. The Influence of Altitude Upon the Flashover and Sparkover Characteristics of Electrical Equipment, S. Whitehead and W. D. Owen. *World Power* (*Lond.*), vol. 14, no. 83, Nov. 1930, pp. 404-414, 21 figs. partly on supp. plates. General nature of dependence of sparkover voltages upon air density; general principles, together with formulas for simple cases; it is shown that, for small changes, discharge voltage is roughly proportional to air density; effect of altitude on air density; different theoretical treatments are discussed and formulas for effect developed; these are criticized, and most appropriate methods of attacking problem are indicated.

SELF-SYNCHRONIZING. The Versatility of Application of Selsyn Equipment, R. A. Corby. *Gen. Elec. Rev.*, vol. 33, no. 12, Dec. 1930, pp. 706-711, 13 figs. Typical installations of indicators and control devices list showing some of uses to which Selsyn apparatus has been adapted with decided advantage; as remove control devices and as remote indicators.

TESTING. The Testing of Protective Gear, W. Wilson. *World Power*, vol. 15, no. 85, Jan. 1931, pp. 17-22, 9 figs. Principles and methods that are made use of in various testing operations to which apparatus is subjected.

Elevators

CONTROL. Electric Levelling Gear for Lifts. *Engineering* (*Lond.*), vol. 130, no. 3387, Dec. 12, 1930, pp. 742-743, 6 figs. Arrangement devised and patented by M. D. Scott, of Marryat and Scott, London, known as Levelectric, employs two motors, smaller being mounted above larger to economize floor space.

ELECTRIC. Higher Car Speeds Proposed for Elevators. *Power*, vol. 73, no. 1, Jan. 6. 1931, pp. 30-31, 2 figs. Developments nearing accomplishment are car speeds of 1200 ft. per min., double-deck cars serving two floors at a time and local and express cars in same hoistway.

Modern Lifts, L. S. Atkinson. *Elec. Times*, vol. 79, no. 2045, Jan. 1, 1931, pp. 5-8, 3 figs. Recent developments and latest types in use.

Electric Lines

AERIAL SURVEYING. Aerial Survey for Transmission Line Location, F. G. Dana. *Civil Eng.* (*N. Y.*), vol. 1, no. 4, Jan. 1931, pp. 249-252, 7 figs. Aerial methods adopted on Bagnell transmission-line location; use of stereoscope for binocular study of overlapping photographs; standard flying equipment used; ground field work; comparison of costs of aerial surveys with direct contact prints and with enlarged prints and ground controls.

PROTECTION. Selective Protection of Two Parallel Feeders with Small Resistance, L. A. Lentin. *Electritchestvo*, no. 20, Oct. 1930, pp. 804-807, 5 figs. Problem of selective protection of two parallel feeders fed on both sides by parallel working power stations is analyzed.

Engineering

HUMAN ASPECTS. Engineering Encounters Human Nature, E. D. Smith. *Mech. Eng.*, vol. 53, no. 1, Jan. 1931, pp. 1-4. Engineer, in launching new technological processes in old world, is not merely putting new wine into old bottles; he is putting high voltage into old wiring; it is important part of task of engineering to see that wiring is made adequate to new load; social responsibility incurred by engineer; effect of introduction of automatic loom in two cases; when technological developments pass from ideas to realities, engineering encounters human nature; engineer's responsibility for adapting mechanism to man.

Furnaces

ENAMELING. Welded Furnaces Meet all Requirements. *Welding Engr.*, vol. 15, no.12, Dec. 1930, pp. 33-36, 12 figs. Application of welding in electric furnaces and conveyors of vitreous-enameling plant of Edison General Electric Appliance Co., manufacturers of "hotpoint" electric appliances, Chicago, Ill.; data on operation and temperatures.

HEAT TREATING. The Use of Electricity in the Heat Treatment and Welding of Metals, A. N. Otis and W. L. Warner. *Mill and Factory Illustrated*, vol. 5, no. 1, Jan. 1930, pp. 48-50, and 92, 9 figs. Features of electrically-heated water-sealed furnaces of Kenworthy type widely used for bright annealing copper wire and similar products.

HIGH FREQUENCY. High Frequency Induction Heating, H. Smethurst, Jr. *Instn. Engrs.—Jl.*, vol. 41, part 3, Dec. 1930, pp. 113-130, 9 figs. History of development; comparison of types.

INDUCTION. Tonnage Melting by Coreless Induction, E. F. Northrup. *Iron Age*, vol. 127, no. 3, Jan. 15, 1931, pp. 228-233, 7 figs. Operating principles and application of high-frequency induction furnaces including data on power requirements, size of furnaces and refractory materials.

Fuses

TESTING. The Detection of Transient Arcs in Metal-Clad Fusible Cutouts, P. D. Morgan and H. W. Baxter. *Instn. Elec. Engrs. —Jl.* (*Lond.*), vol. 69, no. 408, Dec. 1930, pp. 95-99, 8 figs. Directions for employment of neon lamp as substitute for oscillograph in detection of transient low-current arcs between case and poles of metal-clad fusible cut-outs operating under short-circuit conditions. Bibliography.

Generators

DESIGN. Impulse-Short Circuit Generators (Stosskurzschlussgeneratoren), F. Niethammer. *Elektrotechnik und Maschinenbau* (*Vienna*), vol. 48, no. 49, Dec. 7, 1930, pp. 1077-1083. For practical testing of high capacity electric circuit breakers with actual short-circuit capacities, so-called impulse short circuit generators are used in test stands; fundamentals of design of such generator are given.

Increase in Use of Single Element Generators Shown by Survey. *Power Plant Eng.*, vol. 34, no. 24, Dec. 15, 1930, pp. 1418-1422, 2 figs. Study of generating equipment installed in principal power plants of country indicates tendency toward use of large single-element generators rather than double or triple-shaft design inaugurated several years ago; largest single-element machine in use is 160,000 kva. machine in East River station; table illustrating electric-generator practise in 25 power plants.

EXCITATION. Excitation of Generators (Bektachtiging van Generatoren), M. van der Veen. *Polytechnisch Weekblad* (*Amsterdam*), vol. 24, no. 50, Dec. 11, 1930, pp. 851-853, 6 figs. Mathematical analysis by which attempt is made to show along theoretical lines that assumption that magnetizing characteristic of automatically regulated generator should be linear saturation curve, must be incorrect.

SYNCHRONOUS. Permissible Errors in Synchronizing Generators, H. S. Baker. *Elec. News*, vol. 40, no. 1, Jan. 1, 1931, pp. 35-36. Analysis of two common errors, i. e. number of electrical degrees of phase difference between generator and bus at instant of breaker closure; and difference in speeds of generator and bus.

WATERWHEEL. Niagara's Latest Unit. *Elec. News* (*Toronto*), vol. 39, no. 24, Dec. 15, 1930, pp. 65-66, 2 figs. Power plant was finally completed with installation of tenth 58,000 hp. waterwheel-driven generator at Queenston generating station of Hydroelectric Power Commission of Ontario; unit has generator rating of 55,000 kv.a., 12 kv., 80 per cent p. f., 25-cycle, 187.5 r. p. m., while hydraulic turbine is rated at 58,000 hp. at 294 ft. head; total installed generator capacity of this station is now 497,000 kv.a.; enclosed air cooling is applied.

Illumination

INTERNATIONAL CONGRESS. International Illumination Congress, 1931. *Engineer* (*Lond.*), vol. 150, no. 3909, Dec. 12, 1930, p. 646. Congress being arranged by National Illumination Committee of Great Britain, in cooperation with Illuminating Engineering Society; will be held under auspices of International Commission on Illumination, and will take place during September of 1931.

Insulating Materials

PAPER. Paper in the Electrical Industry, W. H. Anderson. *Paper Mill*, vol. 7, no. 52, Dec. 27, 1930, pp. 11-12, and 14. Uses and application of paper in manufacturing electric equipment discussed under headings: condenser paper, wire wrapping paper, paper for laminated phenotic products, mica wrappers, condenser brushing paper, pressboard or fullerboard. Paper presented before Tech. Assn. Pulp and Paper Industry, Dec. 9, 1930.

TEXTILES. Treated Fabrics, A. R. Dunton and A. W. Muir. *Elecn.* (*Lond.*), vol. 105, no. 2741, Dec. 12, 1930, pp. 744-747, 8 figs. Notes on their use for insulating purposes; varnished fabrics and tapes.

Insulators

DESIGN. Designing Insulators to Combat Fog, S. M. Jones. *Elec. World*, vol. 96, no. 25, Dec. 20, 1930, pp. 1139-1142, 6 figs. Deposits are primary cause and fog itself only secondary cause of breakdown; surface leakage resistance is real criterion of performance; suspension string length factor; computing surface leakage resistance; adapting pin design to suspension use.

Lamps

LIFE. Life of Vacuum and Gas Filled Wendel Lamps and Causes of their Burning Out (Ueber die Lebensdauer der luftleeren und gasgefuellten Wendellampen und die Ursachen ihres Durchbrennens), F. Koref and H. O. Plaut. *Zeit. fuer Technische Physik* (*Berlin*), vol. 11, no. 12, 1930, pp. 515-521, 1 fig. Energy consumption are calculated and relation of these to life of lamps are analyzed.

NEON. Neon Lamps (Sulle lampade neon), N. Carrara. *Nuovo Cimento* (*Rome*), vol. 7, no. 8, Aug.-Sept.-Oct. 1930, pp. 318-325, 10 figs. partly on supp. plate. Experimental study of photoelectric sensitiveness of commercial neon lamps manufactured by Philips, Osram etc.

Lighting

AIRPORT. The Application of Illuminating Engineering Principals to Landing Field Floodlighting, L. C. Simpson. *Airports*, vol. 6, no. 1, Jan. 1931, pp. 12-13 and 30, 8 figs. Fundamental considerations of satisfactory landing field floodlighting are illustrated by sketches.

New Styles in Lights, H. C. Ritchie. *West. Flying*, vol. 8, no. 6, Dec. 1930, pp. 59-61, 5 figs. Use and operation of various types of lighting equipment, including beacon, floodlights, boundary lights, etc.; data on power consumption and locating.

MACHINE SHOPS. Lighting the Machine Shop, M. Warren. *Modern Machine Shop*, vol. 3, no. 7, Dec. 1930, pp. 11-14, 16, 18 and 48, 7 figs. Investigation of plants of various companies show effect of proper lighting on efficiency; graph illustrates relation between voltage and light intensity.

Loud Speakers

PROGRAM SERVICE. Latest in Amplifiers and Loudspeakers, W H. Hutter. *Telephony*, vol. 99, no. 25, Dec. 20, 1930, pp. 20-22. New developments in program service amplifiers and loudspeakers; origin of amplifiers and evolution with radio sets. Address read before U. S. Independent Telephone Assn.

Measuring Instruments

ELECTRIC. Switchboard Instruments. *Power Plant Eng.*, vol. 35, no. 1, Jan. 1, 1931, pp. 39-40. Instruments for measurement of voltage, current, power, etc.; instruments for various types of panels; alternating current generator circuits.

Motors

PROTECTION. Modern Methods of Enclosing Electric Motors, P. W. Arnold. *Mill and Factory Industrial*, vol. 8, no. 1, Jan. 1931, pp. 53-55, 13 figs. Problem which arise in protecting motors; most common enclosures; recent developments in enclosing motors.

Built-In Motor Protection, G. R. Anderson. *Indus. Eng.*, vol. 88, no. 12, Dec. 1930, pp. 605-607, 4 figs. Providing protection for inclosed ventilated types. (Continuation of serial.)

RAILROAD. Improvements on Street Car Motors and their Suspension (Perfectionnements apportes aux Moteurs de Tramways et à leur suspension), Castaing. *Industrie des Voies Ferrees et des Transports Automobiles* (*Paris*), vol. 24, no. 287, Nov. 1930, pp. 310-342, 28 figs. Notes with respect to current; supply voltage; operating conditions, modern developments as to magnetic and electric characteristics, mechanical improvements and systems of installation.

SPEED REGULATION. The Rossman System of Speed Control for Alternating-Current Motors. *Engineering* (*Lond.*), vol. 130, no. 3385, Nov. 28, 1930, pp. 694-695, 7 figs. Method is being used in number of American power stations, more particularly for driving forced-draft and induced-draft fans, though it is also applicable to feed pumps and other variable-speed equipment; driving unit consists of constant-speed a.c. motor of either synchronous or induction types, and variable-speed shunt-wound d.c. motor of much smaller output.

Networks

CALCULATION BOARDS. Representation of Generators on an A. C. Calculating Board, W. W. Parker. *Elec. Jl.*, vol. 27, no. 12, Dec. 1930, pp. 718-719, 4 figs. Means for representing synchronous machines; three-phase generator can be represented by single-phase proportional to actual phase-to-neutral terminal or internal voltage; schematic diagram of regulator and phase shifter arrangement for producing power for a.c. calculating board; equipment is described.

INTERCONNECTED. Synchronism Automatically Checked by Substations of Alabama Power Company, E. B. Henry and W. B. Morton. *South. Power Jl.*, vol. 48, no. 12, Dec. 1930, pp. 63-65, 3 figs. Function of synchronism check scheme is to check synchronism between two or more sources of power that are normally in continuous state of synchronism due to interconnection at another station; six synchronism check schemes now in automatic operation; system installed at Montgomery primary substations; operation under normal set-up; protective features.

LIGHTNING. Development of Electric Distribution Networks and Lightning Hazards (Le développement des réseaux de distribution d'énergie électrique et les dangers de la foudre), A. Boutaric. *Revue Gênêrale de l' Electricitê* (*Paris*), vol. 28, no. 22, Nov. 1930, pp. 865-872, 2 figs. Possible influence of overhead network systems on bringing about of electric lightning storms and danger of lightning for individuals and objects near line is analysed.

OVERVOLTAGES. Investigation by Means of Cathode Ray Oscillograph of Excess Voltages caused by Short-Circuit in 8 kilo-volt Distribution Network (Untersuchungen mittels Kathodenstrahl-Oszillograph der durch Erdschluss hervorgerufenen Ueberspannungen in einem 8 k V-Verteilnetz), K. Berger. *Schweiz. Elektrotechnischer Verein* (*Assn. Suisse des Electriciens*)—*Bul.* (*Zurich*), vol. 21, no. 23, Dec. 7, 1930, pp. 756-788, 47 figs. Magnitude and development of excess voltage dependent on location of short circuit; action of obsolete protective equipment and behavior of induction regulator and current transformers are analyzed; deductions are made with respect to insulators.

PLANNING. A Master Plan for Sound Growth in System Expansion. *Elec. News*, vol. 40, no. 1, Jan. 1, 1931, pp. 31-32 and 34. Through coordination and planning it is possible for modern light and power system to get most effective and economical use of money, men and equipment needed; it is possible to operate and build utility in terms of economic facts and business principles whereby waste is eliminated and maximum values are had from current investments.

Oscillographs

CATHODE-RAY. The Position of Cathode Ray Instruments in the Field of Oscillography, O. Ackerman. *Instruments*, vol. 3, no. 12, Dec. 1930, pp. 775-777. Proper field of cathode-ray instruments starts where limitations of moving-coil instruments are reached, i. e., in recording of frequency phenomena over 5000 cycles per sec.; in study of single phenomena (occurring at random) where phenomenon itself must start process of recording with less than 1/50th of sec.; in measuring voltages with negligible loss of power (electrostatic methods); in direct recording of relations where abscissa is electrical quantity; in cases where good visibility of registrations of instrument is required.

Phase Advancers

The Theory and Performance of Phase Advancers, J. J. Rudra and M. Walker. *Instn. Elec. Engrs.—Advance Paper*, 1930, 25 pp., 37 figs. Paper divides advancers into "expedor" advancers in which voltage is proportional to secondary current, and "susceptor" advancers in which it is proportional to secondary voltage; complete theory of expedor advancer is worked out from equivalent circuit, and test results are compared with what might be expected from theory; comparison of advancers of different phase angles under different conditions is made to determine which is best for given purpose; equivalent circuit of susceptor advancer is given and from it complete theory is worked out.

Piezoelectric Quartz

Summary of Piezo-Electric Crystal Conference Held by U. S. Navy Department, December 3-4, 1929. *Inst. Radio Engrs.—Proc.*, vol. 18, no. 12, Dec. 1930, pp. 2128-2135, 3 figs. For purpose of bringing about uniform understanding among conferees, representatives of Naval Research Laboratory offered for discussion; resumé of crystallography and piezoelectricity of quartz; description of methods of cutting and testing quartz used at Naval Research Laboratory; account of experience and practices of laboratory relative to two principal "cuts" used in art.

Power Industry

Congress of the International Association of Producers and Distributors of Electric Power in Brussels, September 1930 (Congrês de Bruxelles de l'Union internationale des Producteurs et Distributeurs d'Energie électrique (Septembre 1930). *Revue Gênêrale de Electricitê* (*Paris*), vol. 28, no. 23, Dec. 6, 1930, pp. 885-894. Grounding of neutral in high and low tension networks; parallel operation of generating stations; joint operation of high tension lines and telephone communication lines.

EMPLOYEES TRAINING. Possible Executives in the Making, J. R. Martin. *Elec. Light and Power*, vol. 8, no. 12, Dec. 1930, pp. 40-43, 1 fig. President's Training Course in Management as originated by Britton I. Budd, president of Public Service Co. of Northern Illinois, is described; company operates in territory approximating 6000 sq. mi. surrounding Chicago, and serves some 318 communities, principally with electricity and gas; approximately 5000 men and women are employed; reasons for selecting number of employes to participate in course in management, and principles and policies governing its administration are set forth.

Power Supply

RURAL. Farm-Service—What of the Future, K. R. Mackinnon. *Elec. World*, vol. 95, Mar. 29, 1930, pp. 657-660, 2 figs. Central-station industry has not evolved coherent and workable policy of national scope for farm service extensions; author cites practices and policies of Nebraska Power company but not necessarily because these are thought to be answer to national problem.

Radio

AERIAL TRANSPORTATION. Wireless Direction Finding, C. B. Carr. *Aircraft Eng.* (*Lond.*), vol. 2, no. 22, Dec. 1930, pp. 305-307. Relative merits of various directional-transmission and reception systems for purpose of assisting air operating company in selection of proper equipment; principles of equi-signal and rotating beacon; Marconi-Bellini-Tosi system; Marconi-Adcock system; Marconi-Robinson system.

The Development of Visual Type of Radio Range Transmitter Having A Universal Application to the Airways, W. E. Jackson and S. L. Bailey. *Inst. Radio Engrs.—Proc.*, vol. 18, no. 12, Dec. 1930, pp. 2059-2101, 35 figs. Visual type of radio range which has universal application to civil airways of United States; relative merits of aural and visual systems of course indication, theory of production of 12 courses by utilizing three-phase radio-frequency source is presented; general description of transmitter; necessary requisites of goniometer design; performance curves of final goniometer illustrate effect of these factors on results.

Aircraft Radio Telephone Successful, R. Johnson. *Telephony*, vol. 99, no. 26, Dec. 27, 1930, pp. 31-32, 2 figs. Demonstration by Air Transport Co. proves that plane-ground voice communications are not only practicable, but successful; discussion of other developments in air transport communication in 1930.

AIRPLANES. System of Guiding Airplanes (Sur un procédé de guidage des avions), Biolt. *Onde Electrique* (*Paris*), vol. 9, no. 103, Nov. 1930, pp. 520-526, 1 fig. System allows for exact location of plane when traveled traject is known; to this end interference zone is created between 2 synchronous emissions and meter installed on receiver of airplane which records number of successive maxima and minima; from this, course traveled is deduced.

AMPLIFIERS. An Amplifier for Measuring Small Currents, R. D. Bennett. *Rev. Sci. Instruments*, vol. 1, no. 8, Aug. 1930, pp. 466-470, 5 figs. Amplifier is described which uses four-electrode tube of ordinary type, and gives maximum current sensitivities of order of 10 to 18 type, and gives maximum current sensitivities of order of 10 to minus 18 power amperes; novel feature consists in using as grid leak positive ion emission of filament.

DESIGN. Effect of Output Load upon Frequency Distortion in Resistance Amplifiers, H. A. Thomas. *Experimental Wireless*, vol. 8, no. 88, Jan. 1931, pp. 11-17, 11 figs. Simple mathematical analysis pertaining to loud-speaker load, input impedance of power-tubes stage, anode circuit impedance of stage 2, amplification of stage 2, input impedance of stage 2, anode circuit impedance of stage 1, amplification of stage 1, overall amplification; experimental results; results obtained; case of 3 stages of low amplification factor tubes; amplification curves.

CONDENSERS. A Variable-Capacitance Cylindrical Condenser for Precision Measurements, and a Wavemeter for Short Wavelengths, E. B. Moullin. *Instn. Elec. Engrs.—Advance Paper received* Nov. 13, 1930, 12 pp., 19 figs. Cylindrical condenser which has been developed for precision measurements at very high radio frequencies; one cylinder is always totally enclosed by other and capacitance is varied by altering distance between axes of cylinders; paper also includes tentative design for short range short wave absorption wavemeter in which same principles of construction are used.

FREQUENCY MEASUREMENT. A New Method of Measurement of Resistance and Reactance at Radio Frequencies, F. M. Colebrook and R. M. Wilmotte. *Instn. Elec. Engrs.—Advance Paper received* Nov. 29, 1930, 10 pp., 9 figs. Method of measuring radio frequency resistance of coils is described; it depends on change in reactance of tube controlled oscillating circuit when it is coupled to circuit under investigation, and does not require any measurement of current or voltage; practical details of working of method and construction of necessary apparatus are given.

GENERATORS. Power Equipment for Aircraft Radio Transmitters, J. D. Miner. *Inst. Radio Engrs.—Proc.*, vol. 19, no. 1, Jan. 1931, pp. 59-77. Systems of power equipment now used or contemplated for supplying power to aircraft radio transmitters; various types of power equipment are described and advantages and disadvantages of each type are discussed.

Power for Aircraft Radio, F. C. Doughman. *Elec. Jl.*, vol. 27, no. 12, Dec. 1930, pp. 701-704, 10 figs. Generators used to supply power for aircraft radio can be driven in wide variety of ways, depending upon size of plane, service for which it is designed, and amount of power required; alternator of inductor type can be combined with d.c. motor to make highly efficient battery driven aircraft unit; oldest and best known type of aircraft power equipment is storage battery driven d.c. dynamotor; constant-speed propeller has made possible use of wind-driven alternator; equipment is illustrated.

Railroads

ELECTRIC. The Contribution of Modern Electrical Equipment to Transportation. H. L. Andrews. *N. Y. Railroad Club—Proc.*, vol. 41, no. 1, Nov. 1930, pp. 9369-9399, 26 figs. and charts. Savings due to electric equipment for street-car lines, trolley buses, gas-electric buses, and electrified steam-railroad transportation systems.

SIGNALS AND SIGNALING. Pennsylvania Installs Centralized Control on 30.3 Miles of Single Track. *Ry. Signaling*, vol. 23, no. 12, Dec. 1930, pp. 434-436, 4 figs. Pennsylvania has completed installation of centralized traffic control between Ben Davis, Ind., and Almeda, which is portion of main line between Indianapolis, Ind., and St. Louis, Mo.; characteristics of line and traffic; 12 min. saved on each freight train stop; second tracking deferred; first installation of Union three-wire coded system.

Remotely-Controlled Interlocking Reduces Operating Costs, R. L. Davis. *Ry. Signaling*, vol. 23, no. 12, Dec. 1930, pp. 429-430, and 433, 4 figs. Michigan Central replaces mechanical plant at crossing of Michigan Central and Grand Trunk Western at Rochester Jct., Mich.; annual saving of $5000 in operating expenses.

Rectifiers

HARMONICS. The Calculation of Harmonics in Rectified Currents, E. L. E. Wheatcroft. *Instn. Elec. Engrs.—Jl.* (*Lond.*), vol. 69, no. 408, Dec. 1930, pp. 106-108, 9 figs. New mathematical method is proposed which treats rectifier characteristic as continuous curve; method of reducing equations to tractable form for solution by successive approximations, using algebra of plane vectors; it is shown by means of numerical example how approximations converge on true value deduced by classical method.

MERCURY ARC. Mercury Arc Rectifier Equipment for the Melbourne Tramways. *Engineer (Lond.)*, vol. 150, no. 3909, Dec. 12, 1930, pp. 655-656, 5 figs. Largest equipment sent to Australia for Melbourno street railroad has capacity of 500 kw., and is designed to operate on 6600-volt, three-phase system and to feed into 600-volt d.c. two-wire system, plant being arranged for fully automatic control; sub-station is brought into operation by means of voltage relay and/or time switch, and is shut down by means of low-current relay or time switch.

Relays

A Thermal Overload Relay, A. E. Capon. *Elec. Jl.*, vol. 27, no. 12, Dec. 1930, pp. 708-709, 4 figs. Relay differs from other thermally operated relays in that heat storage is contained within heater element itself, without any external heat-storing agency; characteristic was obtained by using heater coil of comparatively large mass; to provide protection against instantaneous overload, additional tripping device is connected in series with heating element; operating characteristics with various stationary contact settings, is given in curves.

Resonance

ELECTRIC CIRCUITS. Theory of Two Coupled Oscillatory Circuits (Zur Theorie zwier gekoppelter Schwingungskreise, I), V. Petrzilka. *Elektrische Nachrichten-Technik (Berlin)*, vol. 7, no. 8, Aug. 1930, pp. 317-324, 6 figs. Method of calculation of resonance curves of two circuits from energy supplied to them.

Switchboards

REMOTE CONTROL. Miniature Remote Control Switchboards, L. J. Cissna. *Elec. Jl.*, vol. 27, no. 12, Dec. 1930, pp. 689-695, and 717, 12 figs. Miniature remote-control switchboards represent one of latest developments in switchgear apparatus; development; mounting of control equipment; auxiliary relays; remote metering; wiring; power supply; circuits and their operation; substation equipment; advantages.

STEEL. Development of the Modern Steel Switchboard, E. G. Bern and F. E. Jaquay. *Elec. Light and Power*, vol. 8, no. 12, Dec. 1930, pp. 54, 56 and 58, 7 figs. Development and comparison between older and modern equipment; various examples of modern steel switchboards are illustrated.

Switchgear

METAL CLAD. Metal-Clad Switchgear, R. O. Waltham. *Elec. Light and Power*, vol. 9, no. 1, Jan. 1931, pp. 35-37, 7 figs. Before any manufacturer in United States was ready to supply this type of apparatus, Public Service Co. imported complete distribution substation installation of Reyrolle 4-kv. metal-clad gear and placed equipment in service at Bellwood substation in 1926; experience resulted in development of number of features to adapt gear to American operating conditions which were incorporated in gear subsequently manufactured by Allis-Chalmers Co. under Reyrolle patents.

Telephone

RELAYS. Economics of the Application of Relays to Telephone Circuits, W. W. Wells. *Bell Laboratories Rec.*, vol. 9, no. 5, Jan. 1931, pp. 224-228, 4 figs. To design ideal relay for each particular condition would frequently require design of different relay for each application, and would ultimately result in manufacture of excessive number of types; development of new relay structures, therefore, is not frequently advisable; economic application of existing relay structures; development of new windings and spring arrangements as required.

Trackless Trolleys

MAINTENANCE AND REPAIR. Trolley Buses Cost Less to Maintain than Petrol Buses, C. O. Silvers. *Bus and Coach*, vol. 3, no. 25, Jan. 1931, pp. 3-6, 5 figs. Merits of trackless trolleys as compared to motor bus; tables give data on costs per 100 seat miles; vehicle maintenance and repairs; cost of power and its distribution.

Transformers

CONNECTION. Systems of Transformer Connection. *Power Plant Eng.*, vol. 35, no. 1, Jan. 1, 1931, pp. 44-46, 38 figs. Internal and external connections for various voltage and current combinations.

CONSTRUCTION. Recent Progress in Construction of Transformers of Great Power and Very High Voltage etc. (Recenti progressi nella costruzione dei trasformatori di grande potenza ed altissima tensione considerazioni generali d'impiego), B. Cerretelli. *Elettrotecnica (Milan)*, vol. 17, nos. 28 and 29, Oct. 5, 1930, pp. 638-646, and Oct. 15, pp. 661-672, 54 figs. General review of progress in design of construction, including theoretical analysis of operation of very large transformers, with special reference to transformers of Cardano and Cislago stations, in northern Italy, of 25,000 to 36,000 kva. and 220,000 volts; also description of 1,050,000-volt transformers built for Societa Pirelli.

MAINTENANCE AND REPAIR. Periodic Care of Transformers Cuts Maintenance Costs, A. A. Fredericks. *Power*, vol. 71, no. 9, Mar. 4, 1930, pp. 354-357, 5 figs. Faults that may develop in transformers and how to remedy them.

MANUFACTURE. Fundamentals of Transformer Construction. *Power Plant Eng.*, vol. 35, no. 1, Jan. 1, 1931, pp. 42-44, 6 figs. Types of cores and windings, leads, casings, methods of mounting and cooling; pole type substation for small industrial installations.

TRANSIENTS. Transient Currents in Transformers, H. M. Turner. *Franklin Inst.—Jl.*, vil. 211, no. 1, Jan. 1931, pp. 1-36, 31 figs. Principles underlying phenomena of transient currents in transformers, when connected to source of power, by starting with simple inductive circuits in permanent state and gradually leading up to more involved case of transformer in transient state; elements affecting transient current are considered individually; appendix describes transient visualizer and oscillograph assembly.

Transmission Lines

GROUND WIRE. The Neglected Ground Wire (Den miskjente jordline), W. R. Blumer. *Elektroteknisk Tidsskrift (Oslo)*, vol. 43, no. 32, Nov. 15, 1930, pp. 439-444, 8 figs. Importance of equipping towers for electric high-tension lines with ground wires as protection against lightning; several instances reviewed where lack of adequate grounding caused severe damage to towers; constructions of towers of wood and steel used in Germany and Sweden.

LIGHTNING. Lightning Research in the Field and Laboratory, E. Beck. *Elec. Light and Power*, vol. 9, no. 1, Jan. 1931, pp 59, 62 and 64, 10 figs. Investigative program was carried out during summer of 1930; lightning records were made with automatic cathode ray oscillograph of Norinder type which is automatic within itself and begins to register instant that applied surge voltage exceeds normal line voltage; oscillograms of typical waves measured.

MAINTENANCE AND REPAIR. Live Line Tools for High Voltage Maintenance, W. Smith. *Elec. Light and Power*, vol. 8, no. 12, Dec. 1930, pp. 45-46, 48 and 50, 9 figs. New method of making repairs to high voltage lines was introduced a few years ago which is rapidly coming into general use, making it possible to repair, or even rebuild completely, high voltage lines without taking them out of service; this is done by use of so-called "live line tools," with them, work can be done during regular hours, time required being but slightly greater than with line dead; equipment and its application is described. Paper read before Northwest Elec. Light and Power Assn.

PROTECTION. Theory and Application of Relay Systems, P. H. Robinson and I. T. Monseth. *Elec. Jl.*, vol. 28, no. 1, Jan. 1931, pp. 48-51, 12 figs. Impedance relay is dependent for its operation on both excess current and low voltage; this feature is secured by addition of voltage restraining coil to ordinary over-current relay element; transmission lines operated in parallel can best be protected by use of selective differential current relay; selective-differential relay. (Continuation of serial.)

RELAYS. Interstation Control Wires Avoid Cascade Relaying, G. M. Babcock. *Elec. World*, vol. 95, Mar. 29, 1930, p. 646, 1 fig. Cascade relaying in transmission-line system causes longest time delay at main switching station, where short-circuit current is greatest and should be cleared quickly to avoid serious disturbance on entire system; ideal relaying scheme is one which will work instantaneously with short circuit on line with which it is identified, but remain inoperative with short circuit on any other part of system; Los Angeles Gas & Electric Corporation has operation relay scheme of this character.

WIND PRESSURE. Measurement of the Wind Pressures on Overhead Lines, R. H. Sherlock. *Nat. Elec. Light Assn.—Bul.*, vol. 18, no. 1, Jan. 1931, pp. 29-34, 11 figs. Methods used to carry on experimental study of strength and loading of pole lines, and brief description of instruments which were developed for study of wind gusts; representative data arranged in form adopted for summarizing and interpreting results; no conclusions are presented.

Vacuum Tubes

AMPLIFICATION. Reduction of Distortion and Cross-Talk in Radio Receivers by Means of Variable-Mu Tetrodes, S. Ballantine and H. A. Snow. *Inst. Radio Engrs.—Proc.*, vol. 18, no. 12, Dec. 1930, pp. 2102-2127, 18 figs. In attempting to control audio output of radio receiver employing present types of tubes by varying control grid bias or screen-grid voltage distortion, due to non-linearity of output-input voltage relation for tube, and cross-talk are encountered at higher signal voltages; two shielded tetrode tubes, designated as types 550 and 551, have been developed to reduce these effects.

APPLICATIONS. Industrial Uses of Electron Tubes, W. R. G. Baker, A. S. Fitzgerald and C. F. Whitney. *Electronics*, vol..2, no. 1, Jan. 1931, pp. 467-469, 8 figs. Principal objects which are aimed at in applying electron tubes to power control problems; circuits; notes on features of electron tubes; phase relation control; vacuum-tube control of thyratron; thyratron tuned relay; thyratron flasher; methods of controlling output; a.c. output.

Welding

ARC. Facts Concerning A. C. and D. C. Welding, J. C. Holslag. *Welding*, vol. 1, no. 14, Dec. 1930, pp. 992-993. Favorable and unfavorable characteristics of both processes; a.c. machine is 70 to 90 per cent efficient when considered as piece of electrical apparatus, whereas motor generators and resistance apparatus vary from 50 per cent efficiency electrically down to 5 per cent; first cost, installation and operation are all in favor of a.c. welding.

ATOMIC HYDROGEN. Welding with Atomic Hydrogen Process, S. Martin, Jr. *Welding*, vol. 1, no. 14, Dec. 1930 pp. 990-991, and 998, 6 figs. Proper method for welding steel castings, alloy steels, other metals and the repair of dies; pertinent notes on hydrogen.

AUTOMOBILE. Unusual Welding Jobs in Ford Fabrication. *Am. Mach.*, vol. 73, no. 15, Oct. 9, 1930, pp. 586-588, 5 figs. Method used in manufacture of blanks for differential ring gear, axles, radius rods, mufflers.

JOINTS. How Strong are Welded Joints in Tubular Members of Airplanes, H. L. Whittemore and W. C. Brueggeman. *Iron Age*, vol. 126, no. 26, Dec. 25, 1930, pp. 1925-1926. Paper previously indexed from Am. Welding Soc.—Jl., Sept. 1930.

LOCOMOTIVE BOILERS. Welding Practice on the Illinois Central System. *Boiler Maker*, vol. 30, no. 12, Dec. 1930, pp. 330-335, 7 figs. Rules developed by Illinois Central for fusion welding of locomotive and stationary boilers; instructions for handling oyxgen and acetylene regulations.

MACHINERY. Economies in Welding Machine Parts, J. H. Babcock. *Welding Engr.*, vol. 15, no. 7, July 1930, p. 56, 12 figs. Welded chain guards, gears, wheels, levers and other parts show large savings in cost over riveted construction or castings.

MACHINES. Making Steel Axle Housings by Arc Welding, J. M. Robinson. *Machy. (N. Y.)*, vol. 37, no. 5, Jan. 1931, pp. 329-330, 8 figs. Method of Oakland Motor Car Co., in producing lightweight rear-axle housings by joining steel stampings on automatic arc-welding machine; data on time requirements, tolerances and properties of weld.

New Application of Arc Welding Machine in Street Railroad Practice (Eine Neuartige Verwendung der Lichtbogen-Schweissmaschine im Strassenbahnbetrieb), O. Kranner *Verkehrstechnik (Berlin)*, no. 33, Aug. 15, 1930, pp. 429-430, 2 figs. Possibility of application of arc welding machine for measuring of rail return joints, equipment of street railroads in Graz.

RESEARCH. Practise in Welding Turns to Research. J. R. Griffith. *Welding Engr.*, vol. 15, no. 12, Dec. 1930, pp 29-31, 1 fig. Effect of operator's skill on welds; investigation conducted at Oregon State College on eccentricity of angle connections; stress distribution of welded joint is little, if at all, better than for riveted joint. Paper presented before Int. Acetylene Assn., Chicago, Ill., Nov. 12-14, 1930.

STEEL BUILDINGS. Welding Applied to Two Buildings. *Eng. News Rec.*, vol. 105, no. 24, Dec. 11, 1930, pp. 925-928, 6 figs. Symposium consisting of two articles: Useful Structural Detail Developed for Large All-Welded Building, J. G. Ritter; Contract and Work Procedure on a 14-Story Field-Welded Building, W. F. Carson and F. P. McKibben; construction of 11-story central engineering laboratory building of Westinghouse Electric and Manufacturing Co.; method of erecting six sections of DuPont office building in Wilmington, Del.

Officers and Committees

Institute Officers 1930-1931

President

WILLIAM S. LEE

Junior Past Presidents

R. F. SCHUCHARDT
HAROLD B. SMITH

Vice-Presidents

HERBERT S. EVANS
W. S. RODMAN
C. E. FLEAGER
E. C. STONE
C. E SISSON
H. V. CARPENTER
G. C. SHAAD
I. E. MOULTROP
H. P. CHARLESWORTH
T. N. LACY

Directors

F. C. HANKER
E. B. MEYER
H. P. LIVERSIDGE
J. ALLEN JOHNSON
A. M. MACCUTCHEON
A. E. BETTIS
J. E. KEARNS
F. W. PEEK, JR.
C. E. STEPHENS
A. B. COOPER
A. E. KNOWLTON
R. H. TAPSCOTT

National Treasurer

W. I. SLICHTER

National Secretary

F. L. HUTCHINSON

General Counsel

PARKER & AARON
30 Broad Street, New York

Local Honorary Secretaries

T. J. Fleming, Call B. Mitre 519, Buenos Aires, Argentina, S. A.

H. W. Flashman, Aus. Westinghouse Elec. Co., Ltd., Cathcart House, 11 Castlereagh St., Sydney, N. S. W., Australia.

F. M. Servos, Rio de Janiero Tramways, Light & Power Co., Rio de Janeiro, Brazil.

A. P. M. Fleming, Metropolitan Vickers Elec. Co., Trafford Park, Manchester, England.

A. S. Garfield, 173 Boulevard Haussmann, Paris 8 E., France.

Renzo Norsa, Via Caravaggio 1, Milano 25, Italy.

P. H. Powell, Canterbury College, Christchurch, New Zealand.

M. A. Chatelain, Polytechnical Institute, Apt. 27, Leningrad, Sosnowka 1/3, U. S. S. R.

Axel F. Enstrom, 24a Ingeniorsvetenskrapsakademien, Stockholm, 5 Sweden.

W. Eldson-Dew, P. O. Box 4563 Johannesburg, Transvaal, Africa.

INSTITUTE COMMITTEES

(A list of the personnel of Institute committees may be found in the January issue of ELECTRICAL ENGINEERING)

General Standing Committees and Chairmen

Executive	W. S. Lee
Finance	C. E. Stephens
Meetings and Papers	A. E. Knowlton
Publication	W. S. Gorsuch
Coordination of Institute Activities	H. P. Charlesworth
Board of Examiners	H. W. Drake
Sections	Everett S. Lee
Student Branches	W. H. Timbie
Membership	J. Allen Johnson
Headquarters	R. H. Tapscott
Law	E. B. Meyer
Public Policy	Bancroft Gherardi
Standards	F. D. Newbury
Edison Medal	D. C. Jackson
Lamme Medal	Charles F. Scott
Code of Principles of Professional Conduct	F. B. Jewett
Award of Institute Prizes	A. E. Knowlton
Safety Codes	A. W. Berresford
Engineering Profession	H. A. Kidder
Columbia University Scholarships	W. I. Slichter
Popular Science Award	A. E. Knowlton
Advisory Committee to the Museum of Science and Industry in the City of New York	J. P. Jackson

Technical Committees and Chairmen

Automatic Stations	F. Zogbaum
Communication	G. A. Kositzky
Education	W. R. Work
Electrical Machinery	Philip L. Alger
Electric Welding	P. P. Alexander
Electrochemistry and Electrometallurgy	P. H. Brace
Electrophysics	O. E. Buckley
General Power Applications	C. W. Drake
Instruments and Measurements	E. J. Rutan
Applications to Iron and Steel Production	A. C. Cummins
Production and Application of Light	George S. Merrill
Applications to Marine Work	R. A. Beekman
Applications to Mining Work	Carl Lee
Power Generation	F. A. Allner
Power Transmission and Distribution	P. H. Chase
Protective Devices	Raymond Bailey
Research	L. W. Chubb
Transportation	Sidney Withington

INSTITUTE REPRESENTATIVES

(The Institute is represented on the following bodies; the names of the representatives may be found in the January issue of ELECTRICAL ENGINEERING)

Aeronautical Radio Research, Liaison Committee on
Alfred Noble Prize Committee, A. S. C. E.
American Association for the Advancement f Science, Council
American Bureau of Welding
American Committee on Electrolysis
American Engineering Council Assembly
American Marine Standards Committee
American Standards Association
American Year Book, Advisory Board
Charles A. Coffin Fellowship and Research Fund Committee
Committee of Apparatus Makers and Users, National Research Council
Committee on Elimination of Fatigue, Society of Industrial Engineers
Committee on Heat Transmission, National Research Council
The Engineering Foundation
Engineering Societies Monographs Committee
Hoover Medal Committee
John Fritz Medal Board of Award
Joint Committee on Welded Rail Joints
Joint Conference Committee of Four Founder Societies
Library Board, United Engineering Trustees, Inc.
National Fire Protection Association, Electrical Committee
National Fire Waste Council
National Research Council, Engineering Division
National Safety Council, Electrical Committee of A. S. S. E.—Engineering Section
Radio Advisory Committee, Bureau of Standards
United Engineering Trustees, Inc.
U. S. National Committee of the International Commission on Illumination
U. S. National Committee of the International Electrotechnical Commission
Washington Award, Commission of

GEOGRAPHICAL DISTRICT EXECUTIVE COMMITTEES

District	Chairman (Vice-President, A. I. E. E.)	Secretary (District Secretary)
No. 1—North Eastern	I. E. Moultrop, Edison Elec. Illum. Co., 39 Boylston St., Boston, Mass.	A. C. Stevens, General Electric Co., Schenectady, N. Y.
No. 2—Middle Eastern	E. C. Stone, Duquesne Light Co., 435 Sixth Ave., Pittsburgh, Pa.	J. A. Cadwallader, Bell Tel. Co. of Pa., 416 Seventh Ave, Pittsburgh, Pa.
No. 3—New York City	H. P. Charlesworth, 463 West St., New York, N. Y.	C. R. Jones, Westinghouse E. & M. Co., 150 Broadway, New York, N. Y.
No. 4—Southern	W. S. Rodman, Box 675, University, Va.	J. S. Miller, Jr., Box 12, University, Va.
No. 5—Great Lakes	T. N. Lacy, Mich. Bell Tel. Co., 1365 Cass Ave., Detroit, Mich.	A. G. Dewars, No. States Pr. Co., 15 S. 5th St., Minneapolis, Minn.

GEOGRAPHICAL DISTRICT EXECUTIVE COMMITTEES—*Continued*

District	Chairman (Vice-President, A. I. E. E.)	Secretary (District Secretary)
No. 6—North Central	Herbert S. Evans, University of Colorado, Boulder, Colo.	M. S. Coover, University of Colorado, Boulder, Colo.
No. 7—South West	G. C. Shaad, University of Kansas, Lawrence, Kans.	Robert W. Warner, University of Kansas, Lawrence, Kans.
No. 8—Pacific	C. E. Fleager, Pac. Tel. & Tel. Co., 140 New Montgomery St., San Francisco, Calif.	H. W. Hitchcock, 1050 Telephone Bldg., 740 South Olive St., Los Angeles, Calif.
No. 9—North West	H. V. Carpenter, State College of Washington, Pullman, Wash.	R. D. Sloan, State College of Washington, Pullman, Wash.
No. 10—Canada	C. E. Sisson, Canadian Gen. Elec. Co., 1025 Lansdowne Ave., Toronto, Ont.	W. L. Amos, Hydro-Elec. Pr. Com., 190 University Ave., Toronto, Ont.

Note: Each District Executive Committee includes the chairmen and secretaries of all Sections within the District and the chairman of the District Committee on Student Activities.

LOCAL SECTIONS OF THE INSTITUTE

Name	District	Chairman	Secretary	Secretary's Address
Akron	2	H. C. Paiste	Alvin P. Regal	Phila. Rubber Works Co., Akron, Ohio
Atlanta	4	H. O. Uhl	O. O. Rae	Westinghouse E. & M. Co., Atlanta, Ga.
Baltimore	2	W. B. Kouwenhoven	J. Wells	Western Elec. Co., 25 Broening Rd., Baltimore, Md.
Birmingham	4		O. E. Charlton	Allied Engineers, Inc., Birmingham, Ala.
Boston	1	J. P. Kobrock	G. J. Crowdes	Simplex Wire & Cable Co., Sidney St., Cambridge, Mass.
Chicago	5	F. H. Lane	L. R. Mapes	Ill. Bell Tel. Co., 212 W. Washington St., Chicago, Ill.
Cincinnati	2	T. C. Reed	L. L. Bosch	Columbia Eng. & Mgt. Corp., 314 West 4th St., Cincinnati, Ohio
Cleveland	2	F. W. Braund	John M. Smith	Nela Park, Cleveland, Ohio
Columbus	2	C. D. Price	K. Y. Tang	Ohio State University, Columbus, Ohio
Connecticut	1	Samuel Ferguson	R. G. Warner	Yale Univ., 10 Hillhouse Ave., New Haven, Conn.
Dallas	7	L. T. Blaisdell	G. A. Dyer	Southwestern Bell Tel. Co., Dallas, Texas
Denver	6	R. B. Bonney	N. R. Love	807 Tramway Bldg., Denver, Colo.
Detroit-Ann Arbor	5	LeRoy Braisted	J. J. Shoemaker	Detroit Edison Co., 2000-2nd Ave., Detroit, Mich.
Erie	2	G. R. McDonald	G. I. LeBaron	General Elec. Co., Erie, Pa.
Fort Wayn	5	W. J. Morrill	C. M. Summers	General Elec. Co., Fort Wayne, Ind.
Houston	7	C. D. Farman	Hezzie Clark	Humble Pipe Line Co., Drawer, 1761, Houston, Texas
Indianapolis-Laf.	5	E. G. Ralston	C. E. Dutton	15 W. New York St., Room 222, Indianapolis, Ind.
Iowa	5	J. K. McNeely	H. B. Hoffhaus	Des Moines El. Lt. Co., 312-6th Ave., Des Moines, Iowa
Ithaca	1	W. C. Ballard, Jr.	W. E. Meserve	614 E. Buffalo St., Ithaca, N. Y.
Kansas City	7	J. S. Palmer	Richard M. Ryan	510 Dwight Bldg., Kansas City, Mo.
Lehigh Valley	2	W. M. Harbaugh	J. H. Diefenderfer	Penn. Pr. & Lt. Co., Hazleton, Pa.
Los Angeles	8	H. W. Hitchcock	Philip S. Biegler	3551 University Ave., Los Angeles, Calif.
Louisville	4	James Clark, Jr.	Philip P. Ash	L. & N. R. R. Bldg., 9th and Broadway Ave., Louisville, Ky.
Lynn	1	A. L. Ellis	W. K. Dickinson	General Elec. Co., West Lynn Works, Lynn, Mass.
Madison	5	L. C. Larson	G. F. Tracy	Elec. Lab. Bldg., Univ. of Wisconsin, Madison, Wis.
Memphis	4	M. Eldredge	W. A. Gentry	Memphis Pr. & Lt. Co., Memphis, Tenn.
Mexico	3	B. E. Arias	L. Castro, Jr.	Departamento Electricidad y Telegrafos, Ferrocarriles Nacionales de Mexico, Mexico, D. F.
Milwaukee	5	F. A. Kartak	I. L. Illing	Milwaukee El. Ry & Lt. Co., 330 Pub. Serv. Bldg., Milwaukee, Wis.
Minnesota	5	D. K. Lewis	H. J. Pierce	Northwestern Bell Tel. Co., Minneapolis, Minn.
Nebraska	6	W. O. Jacobi	A. L. Turner	1112 Telephone Bldg., Omaha, Nebraska
New York	3	J B. Bassett	C. R Jones	Westinghouse E. & M. Co., 150 Broadway, New York, N. Y.
Niagara Frontier	1	E. S Bundy	G. W. Eighmy	General Elec. Co., 1100 Elec. Bldg., Buffalo, N. Y.
North Carolina	4	J. H. Paget	F. C. DeWeese	Carolina Pr. & Lt. Co., Raleigh, N. C.
Oklahoma City	7	F. J. Meyer	C. E. Bathe	Oklahoma Gas & Elec. Co., Oklahoma City, Okla.
Philadelphia	2	D. H. Kelly	J. L. MacBurney	El. St. Bat. Co., 1955 Hunting Park Ave., Phila., Pa.
Pittsburgh	2	C. T. Sinclair	F. A. Connor	General Elec. Co., 1309 Oliver Bldg., Pittsburgh, Pa.
Pittsfield	1	C. H. Kline	L. H. Burnham	General Electric Co., Pittsfield, Mass.
Portland, Ore.	9	A. H. Kreul	C. W. Fick	General Electric Co., Portland, Oregon
Providence	1	J. W. Young	O. W. Briden	Blackstone Valley G. & E. Co., 231 Main St., Pawtucket, R. I.
Rochester	1	Harvey J. Klumb	F. C. Young	Stromberg-Carlson Co., 100 Carlson Rd., Rochester, N. Y.
St. Louis	7	C. B. Fall	E. A. Forkner	Wagner Elec. Corp., 6400 Plymouth Ave., St. Louis, Mo.
San Antonio	7	D. W. Flowers	E. Bissett	San Antonio P. S. Co., 201 N. St., Mary St., San Antonio, Texas
San Francisco	8	P. B. Garrett	E. F. Maryatt	Pacific G. & E. Co., 245 Market St., San Francisco, Calif.
Saskatchewan	10	W. T. Hunt	A. B. Coward	Light and Power Dept., Regina, Sask., Canada
Schenectady	1	E. S. Henningsen	E. P. Nelson	D. C. Eng. Dept. General Elec. Co., Schenectady, N. Y.
Seattle	9	C. E. Carey	Philip D. Jennings	5560 Stuart Bldg., Seattle, Wash.
Sharon	2	S. S. Cook	R. M. Field	Westinghouse E. & M. Co., Sharon, Pa.
Southern Virginia	4	J. H. Berry	Cecil Gray	Westinghouse E. & M. Co., 912 El. Bldg., Richmond, Va.
Spokane	9	Loren A. Traub	C. F. Norberg	Washington Water Pr. Co., Spokane, Wash.
Springfield, Mass	1	J. N. Alberti	L. C. Packer	Westinghouse E. & M. Co., Page Blvd., Springfield, Mass.
Syracuse	1	F. E. Verdin	Charles W. Henderson	504 University Pl., Syracuse, N. Y.
Toledo	2	F. H. Dubs	Max Neuber	1257 Fernwood Ave., Toledo, Ohio
Toronto	10	D. A. McKenzie	G. D. Floyd	Hydro El. Pr. Comm., 190 Univ. Ave., Toronto, Ont.
Urbana	5	C. E. Skroder	W. J. Putnam	123 Mat. Test. Lab. Univ. of Illinois, Urbana, Ill.
Utah	9	L. B. Fuller	Paul Ranson	Utah Apex Mining Co., Bingham Canyon, Utah
Vancouver	10	H. Vickers	C. Arnott	B. C. E. Ry. Co., Ltd., 425 Carrall St., Vancouver, B. C.
Washington	2	George W. Vinal	J. L. Carr	General Elec. Co., 800-15th St., N. W., Washington, D. C.
Worcester	1	J. K. Oldham	R. P. Bullen	General Elec. Co., Worcester, Mass.
Total 58				

STUDENT BRANCHES OF THE INSTITUTE

Name	Location	District	Chairman	Secretary	Counselor (Member of Faculty)
Akron, Univ. of	Akron, Ohio	2	Harmon Shively	H. H. Schroeder	J. T. Walther
Alabama Poly. Inst	Auburn, Ala	4	R. Mann		W. W. Hill
Alabama, Univ. of	University, Ala	4	Walter H. Croft	Harold B. Hendrix	F. R. Maxwell, Jr.
Arizona, Univ. of	Tucson, Ariz	8	W. T. Brinton	Carl Ludy	J. C. Clark
Arkansas, Univ. of	Fayetteville, Ark	7	Ned S. Muse	E. Wylie Head	W. B. Stelzner
Armour Inst. of Tech	Chicago, Ill	5	K. A. Knittel	E. Squires	D. E. Richardson

Industrial Notes

The Ward Leonard Electric Company, Mount Vernon, N. Y., has appointed the Beedle Equipment Company as sales representative in the Cincinnati and Dayton districts. Offices are located at 1309 Union Trust Building, Cincinnati, Ohio.

Weyerhaeuser Appoints Ray V. Clute.—According to a recent announcement, Ray V. Clute has been appointed manager of cedar pole sales of the Weyerhaeuser Sales Company with headquarters at Chicago. He has been associated with the company since 1916.

New Circuit Breaker.—A new indoor oil circuit breaker with enclosed type mechanism and all poles in one tank, known as type DR-25, has been developed by the Condit Electrical Mfg. Corporation, Boston. This breaker offers the features of non-oil-throwing, greater clearances, quick clearing operation, small space requirements and provision for venting gases. It is furnished three or four pole, manually or electrically operated for 600, 800 and 1200 amperes at 15,000 volts. The estimated interrupting capacity is 2500 amperes at 15,000 volts.

Construction Begins on G-E Cleveland Plant.—Construction of a $1,000,000 plant, the first unit of an extensive development in Cleveland by the General Electric Company has been started by the Austin Company, engineers and builders of Cleveland, and will be completed by August 1. A definite upturn in business and the fact that building costs are the lowest in years were factors leading to the decision to start expansion projects at this time. When completed the new plant will employ 1,000 workers. The project will be erected on a 23-acre site in Euclid, ten miles east of downtown Cleveland, and about three miles from Nela Park, the extensive research laboratories of the company. In the plant will be made all of the wire filament for incandescent lamps, in addition to all gases used in the works of the lamp company.

Trade Literature

Waterwheel Generators.—Bulletin GEA-820A. Describes vertical waterwheel-driven generators. Such units range in size from 30 to 77,500 kv-a. General Electric Co., Schenectady, N. Y.

Arc Welding Supplies.—Bulletin 3304, 20 pp. Describes welding rods, shields, holders, cables, protective clothing, and other accessories. The Lincoln Electric Company, Cleveland.

Turbine-Generator Units.—Bulletin 1835-A. Describes Westinghouse 3600 r. p. m. steam-turbine-generator units. Westinghouse Electric & Manufacturing Company, East Pittsburgh.

Insulator Glaze.—Bulletin, 10 pp. Treats of the glaze of porcelain insulators and its influence on insulator life and strength. Locke Insulator Corporation, So. Charles and Cromwell Streets, Baltimore.

Synchronous Condensers.—Bulletin GEA-1337, 20 pp. Describes small synchronous condensers for improving power factor and for maintaining correct voltage in industrial plants. General Electric Company, Schenectady, N. Y.

Vulcanized Fibre.—Bulletin, 40 pp. Describes "Diamond" vulcanized fibre. The process of manufacture is illustrated and uses of the product, widely applicable in electrical fields, are illustrated. Continental-Diamond Fibre Company, Newark, Del.

Motors.—Bulletin 169, 8 pp. Describes Wagner slip-ring motors, four different types, speed torque characteristics and control equipment necessary for starting. Wagner Electric Corporation, 6400 Plymouth Avenue, St. Louis.

Insulated Aluminum Conductors.—Bulletin, 16 pp. Describes "Alectral" insulated aluminum wires, cables and fittings. The advantages of the new type conductors for various applications are outlined. General Cable Corporation, 420 Lexington Avenue, New York.

Phosphor Bronze—Nickel Bronze.—Bulletins, each 32 pp., describe various alloys of these metals, their characteristics and uses. The Riverside Metal Company, Riverside, N. J.

Relays.—Bulletin GEA-970B, 48 pp. Describes type PQ relays, designed primarily for alternating-current service and for use in protecting circuits and connected apparatus in general, in cases of overcurrent and short circuit. General Electric Company, Schenectady, N. Y.

Battery Locomotives — Transfer Cars.—Bulletin 1237, 16 pp. Describes storage battery locomotives, special cars for transportation of transformers, coal and ash cars, turn tables and other equipment supplied to central stations and large industrial power plants. The Atlas Car & Manufacturing Company, Cleveland.

Welded Pipe Gas Lines.—Bulletin 510, 52 pp. Describes "Smithwelded" pipe for gas lines. The bulletin includes detailed methods for determining design, stresses, weights, costs, etc. Photographs are included of some of the installations, which range in length to over 700 miles. A. O. Smith Corporation, Milwaukee.

Ash Conveyors.—Bulletin, 20 pp. Describes "Nuveyor" ash conveyor systems, designed primarily to meet the requirements of clean and economical ash disposal for large power plants. The capacities of such systems range from 3 to 30 tons per hour, and may be used in conjunction with either stoker-fired or pulverized fuel firing. United Conveyor Corporation, Old Colony Building, Chicago.

Smoke Recorder.—Circular. Describes the new L & N smoke recorder. The recording installation consists of a measuring chamber at the stack or breeching, a chart recorder at any convenient location, and an indicator at the boiler. For central stations these devices assist in meeting ordinance requirements, maintaining minimum smoke density and inducing economy in firing. Leeds & Northrup Company, 4901 Stenton Avenue, Philadelphia.

Fans.—Bulletin 41, 12 pp. Describes "Century" fans for alternating and direct-current, stationary, oscillating, ceiling and ventilating fans. Included in the bulletin is a new 8-in. one-speed fan for alternating current; also the "Reversair" 36-in. and 60-in. a-c. ceiling fans in which the direction of the rotation of the fan may be reversed, permitting either upward or downward air delivery. Century Electric Company, 1806 Pine Street, St. Louis.

Street Lighting.—Catalog 218-A, 126 pp., "Utilitarian Street Lighting Equipment," and catalog 218-B, 100 pp. "Ornamental Street Lighting Equipment." The former publication describes types of street lighting equipment in which the current is carried to the lighting units by overhead wiring, to distinguish installations of this character from "ornamental" street lighting systems, in which use is made of underground cable construction. Each of these publications includes general information regarding street lighting installations, descriptions and photographs of various street lighting units, standards and street lighting accessories. Westinghouse Electric & Manufacturing Company, East Pittsburgh.

CORRECTION. In "Light Beams Operate Traffic Signals," by R. C. Hitchcock (March issue), the third paragraph, fifth line, page 183, should read, "lenses and resulting *in* (not *from*) the apparatus going on. . . ."

◆

DEMONSTRATING Institute activities in the advancement of electrical engineering one has only to review the subjects on the winter convention program, partial discussion for which appears on *page 299*, also papers given at the recent district meeting at Pittsburgh (*page 296*) and the tentative program for the Rochester meeting (*page 302*).

◆

SINCE the low-voltage a-c. distribution network has already proved its reliability in sections where high load densities prevail, it seems natural to think of this system being developed *vertically* to meet the load demands of very tall buildings. A. H. Kehoe, of the United Electric Light and Power Company is well qualified to give information on this subject having been in responsible charge of the development work on vertical networks since their inception. Basset Jones of Meyer, Strong & Jones, New York City a coauthor with Mr. Kehoe, has for many years been associated with building illumination and power problems. (*See page 292*)

◆

"CRACKING" low-grade oils by electricity to convert them into usable gasoline and other volatile fluids has been achieved through perseverance and super-detailed experimentation. This has been made the subject of a paper which H. R. Rowland has presented before the Institute's Kansas City Section. (*See page 288*)

◆

THE ELECTROPURE method of pasteurizing, in which an electric current is actually passed through the milk itself is the subject interestingly discussed by A. J. Dreux of the Rieck-McJunkin Dairy Company of Pittsburgh (where the process is in practical use) and H. C. Brunner, general engineer of the Westinghouse Electric & Manufacturing Company. (*See page 285*)

◆

DEVELOPING a protective relay system for long transmission lines where stability plays such a master role, is a difficult problem indeed. E. R. Stauffacher, electrical protective engineer of the Southern California Edison Company, Ltd., reviews a decade of his experiences in this work on the lines in Southern California where the situation has been further complicated by rapid and extensive system growth. (*See page 268*)

◆

OF no minor importance is the consideration of noise-frequency induction which constituted part of a symposium given at the Institute's winter convention the major features of which are abstracted in this issue. This is especially significant in view of the coordination problems involved between power and communication circuits represented respectively by H. L. Wills of the Georgia Power Company, and O. B. Blackwell of the American Tel. & Tel. Co. (*See page 279*)

Electric Communication and the New York Stock Exchange

Electric communication has grown to be an extremely important aid in the speedy transaction of business. This is especially true of the New York Stock Exchange with its hundreds of private telephone lines, thousands of high-speed tickers, and a telephone quotation bureau which handles as many calls per hour as a large central telephone office.

By Dean K. Worcester

Associate A. I. E. E.

Assistant Secretary, New York Stock Exchange

IT IS DIFFICULT to imagine a business or industry more dependent upon electric communication systems than that of a stock exchange. Perhaps the underlying reason is that no man can succeed in this business whose word is not as good as his bond; and so the telephone and the telegraph handle innumerable transactions which would otherwise require the services of the typewriter and the postman. In any event, the growth of the electrical transmission of intelligence since 1867, when the first stock ticker was placed in the New York Stock Exchange, and 1878, when the first telephone was installed there, has been rapid and continuous; and although the Exchange founded in 1792 has had the benefits of these devices for less than half of its history, one does not like to contemplate what would result today if these facilities were suddenly taken from it.

Many persons, especially communication engineers, are familiar with the great network of wires that connects Wall Street with brokerage offices, banks, investment houses, and similar institutions throughout the country. The myriad of lines, however, which enter the group of buildings comprising the Stock Exchange seem to be clothed in mystery. For this, two factors are probably mainly responsible. First, the impracticability of admitting the public onto the trading floor itself, where most of these wires have either their beginning or ending; and second, the inexorable supervision maintained by the Exchange over these vital wire connections, to prevent their improper use by gentry of uncertain antecedents and motives.

BUSINESS OF THE EXCHANGE

The Exchange itself, be it clearly understood, does not buy or sell securities; it determines no prices, has no official quotations, and keeps no record of the transactions made upon its floor. It exists for the purposes set forth in Article I of its Constitution; namely, "to furnish exchange rooms and other facilities for the convenient transaction of their business by its members; to maintain high standards of commercial honor and integrity among its members; and to promote and inculcate just and equitable principles of trade and business."

The business which the members of the Exchange transact upon its floor is the making of contracts to purchase or sell such securities as are approved and admitted to dealing by a committee of the Exchange chosen for this purpose.

The rooms which the Exchange provides comprise at present a "board room" which, with its annex, has an area of about 22,000 sq. ft., and a "bond room" with an area of some 6,000 sq. ft. In these rooms some 1,350 stocks and 1,500 issues of bonds are dealt in. Contracts may be made only by members, (of whom there are now 1,352), and this power may not be delegated to anyone save another member. About 1,000 members are present each day upon the floor. Contracts are oral only, no written contracts nor memoranda being exchanged upon the floor. Settlement of contracts by the delivery of securities and payment of money is handled elsewhere.

Among the facilities provided by the Exchange to aid its members in the transaction of their business upon the floor are:

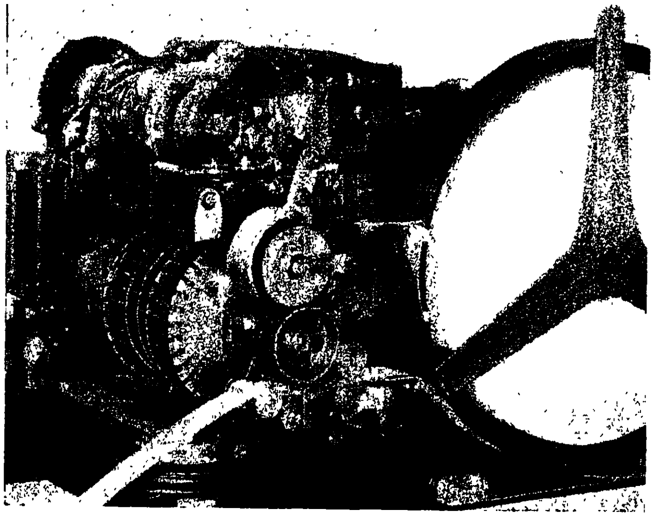
1. Approximately 1,400 telephone spaces located around the edge of the trading floor where members may install private-wire connections to their offices or to the offices of other members. At these spaces members may also station their own telephone clerks who attend to the handling of orders, reports, and other business over the wires, leaving the member free to execute orders—an invaluable assistance.

2. A telephone quotation bureau, to which the bid and asked prices of stocks are continuously reported by a number of employees on the floor. Members having nearby offices may be connected by private telephone lines with this bureau, and may thus obtain within a few seconds the price bid for a stock, and the price at which it is offered, irrespective of whether or not a sale has recently taken place.

3. About 1,100 employees of the Exchange regularly stationed upon the floor carry messages, transmit written orders through pneumatic tubes (of which there are 35 miles beneath the floor), take down reports of transactions and cause them to be printed on the ticker tape, report bid and asked prices to the telephone quotation bureau, and perform other services.

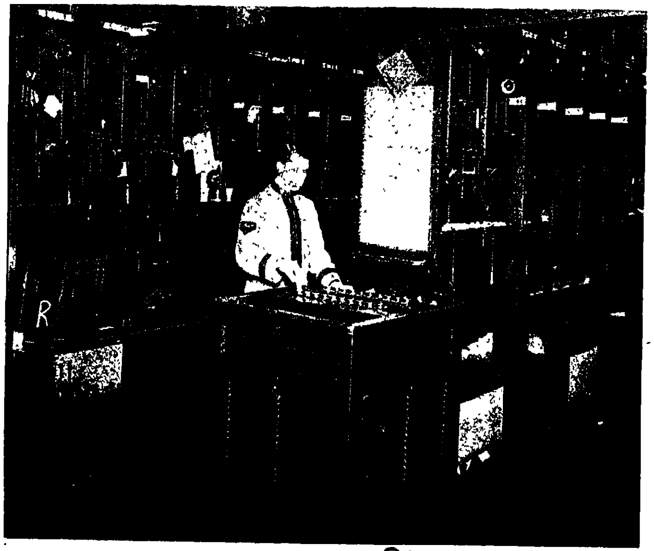
4. Ticker service which is rendered by a subsidiary, the New York Quotation Company, to members of the Exchange located south of Chambers Street in Manhattan. Under a non-exclusive contract the ticker quotations are made available to the Western Union Telegraph Company, by which they are retransmitted to other members and approved non-members located in the United States, Canada, and Cuba.

Written especially for ELECTRICAL ENGINEERING, based upon an address delivered before the Communication Group, New York Section, A. I. E. E., Jan. 6, 1931.



© New York Stock Exchange

New high-speed stock ticker with cover removed



© New York Stock Exchange

Section of private-wire telephone booths. Pneumatic-tube station shown in the foreground

Note that many of the receivers are not replaced on their hooks but are simply dropped and left hanging. The receiver cords have been looped around the hooks, their weight being sufficient to pull the hooks down and thereby break the connection

The procedure by which an order to buy or sell stock is normally handled is outlined in the following.

HANDLING AN ORDER

An order received in a member's office is telephoned to the floor over one of the private lines and taken down on an order slip by the member's telephone clerk. The clerk summons his broker by means of an extensive annunciator system and gives him the order. The broker then goes to the point on the floor at which trading is done in the stock in question, each stock having its own definite location. Having bought the stock, or sold it, as the case may be, he notes on the slip the name of the member or firm with whom he has traded, and the price. He then returns the slip to the telephone clerk who in turn reports the execution to his office over the private wire.

It is thus evident that the system of private wires which connects the floor with the offices of members is an indispensable link in the handling of their business. There are about 2,300 such wires, each entirely independent of the others, and it is estimated that on a moderately active day more than 2,000,000 calls are made over these wires during the five hours of trading. Obviously, a member whose communications are interrupted, delayed, or confused, even for a few minutes, would find himself for the time being practically unable to do business.

The simple private telephone line, consisting essentially of a pair of conductors having at each end a telephone instrument, a bell, and a ringing key, has proved to be admirably suited for this exacting service. It combines to a high degree the fundamental requirements of simplicity, speed, and surety.

There can be no misunderstanding as to the identity of the person on the other end of the line, for no switching takes place; the possibility of breakdown is made as remote as possible; and messages can be passed as fast as people can talk. Furthermore, any intermediary switching device would make it less difficult for unauthorized and unscrupulous persons to get into communication with the Exchange floor; and so it is a rigid requirement of the Exchange that all lines shall be private, and shall terminate at each end either in a separate instrument, or in a simple key-set, turret, or monitor, which, if used, shall be restricted exclusively to the use of such lines. The lines themselves are installed by the New York Telephone Company under a contract with the Exchange, and may be connected, moved, or disconnected, only by an order from the Exchange.

HIGH-SPEED TICKER SYSTEM

A wholly different communication problem is presented by the ticker system.

The present ticker instrument is simply a high-speed printing telegraph, controlled over a single-wire circuit, and driven from a local power source, usually the subscriber's lighting system. The New York Quotation Company owns and operates approximately 2,500 tickers, together with underground conductors, transmitting apparatus, and other equipment, all located as described, in southern Manhattan. This company has exclusive access to the Exchange floor for obtaining reports of transactions. The Western Union Telegraph Company obtains quotations from a New York Quotation Company ticker; re-transmission is effected by that company by means of an ingenious double-manual keyboard which without disturbing the sequence of quotations enables two operators to cooperate in copying them from the tape, the operating speed of 500 characters per minute being far too great for one person to handle.

Among the 1,100 Exchange employees stationed on the floor are more than 200 reporters who make note of each transaction as it occurs, writing on a slip of paper the name of the security, (abbreviated, of course), the amount sold, and the price. These slips are dispatched without delay to a transmitting operator, who sits at a perforator keyboard and perforates a paper tape with the code corresponding to the characters which are to be printed. There are six such transmitting stations, which were formerly located at separate points on the floor. Recently these have been brought together on an elevated platform, to which point the report slips are sent through pneumatic tubes.

The six perforated tapes are summarized by a reperforator on a master tape which passes through a master transmitter and operates the ticker system. At each of the six stations just mentioned a ticker is provided, and in order to detect any errors which may have crept in, the report slips after being transcribed by the keyboard operator are immediately and carefully compared with the printed tape.

The Exchange uses every effort to make the ticker tape an accurate and punctual record of what takes place on the floor; but in spite of safeguards and notwithstanding the high level of mechanical and electrical precision at which the ticker system is maintained, errors must sometimes occur. Consequently, the tape cannot be, and is not, looked upon as an official record but merely as the best record that it is possible to keep.

It is regrettable that the historic days of 1929, with the resulting market activity which continued into the early summer of 1930, did not hold themselves in abeyance a few months more; for on September 2, 1930, the new high-speed ticker system operated as such for the first time, but since that date has had little opportunity to test its capacity in a really active market. The old ticker system printing 275 characters per min. found difficulty in keeping abreast of a four-million-share day,

General view of trading floor of the New York Stock Exchange showing (A) private-wire telephone booths; (B) trading posts; (C) annunciator call-boards for brokers; (D) money desk; (E) pneumatic-tube stations connecting trading posts with telephone booths and on eight- or ten-million-share days the tape was sometimes hours behind the market.

The new ticker prints 500 characters per minute or slightly less than twice as many as the old machine. Yet its adequacy in terms of shares of stock is believed to be far greater than this two-to-one ratio. Records show that as the volume of trading increases, the number of tape impressions per hundred shares of stock sold falls off sharply, thus enabling a given number of impressions (such as the number that can be printed during one hour) to record a far larger amount of stock. For example, on a four-million-share day the average number of impressions per hundred shares is about 2.0; at eight million shares per day this figure is more nearly 1.4; and at twelve million shares, the data though they are few indicate that the coefficient is about 1.1. The reasons for this are twofold; first, the Exchange itself takes steps to abbreviate the record on the tape by omitting volume figures or by printing only the last digit and fraction of the price instead of the full price; and second, the average number of shares of stock per transaction becomes larger, yet it takes only a little more work for the ticker to record a sale of 5,000 shares than a sale of 200 shares.

In any event, the new ticker can print 150,000 characters during the five hours of trading; if the number of required impressions per hundred shares is 2.0, the ticker can thus record 7,500,000 shares; but at 1.1 impressions per hundred shares, the ticker could keep effective pace with a turnover of about 13,500,000 shares per day. Of course trading does not run at a uniform rate even for a single day; but it seems safe to expect that the ability of the new ticker to keep pace with the market will prove much greater than its printing speed alone would indicate.

General view of telephone quotation bureau before installation of bulletin boards

TELEPHONE QUOTATION BUREAU

The telephone quotation bureau makes available to members' offices on short notice the latest bid and asked prices of any stock they may desire. By bid and asked prices are meant the prices at which stock can be sold (bid) or purchased (asked)—information which is obviously of considerable value to a person who contemplates placing an order to buy or sell. Prior to the early part of 1929 this could be done only by telephoning the floor via one of the private wires. A broker or page would then be sent to the place on the floor where the stock in question was being traded (often a hundred feet or more away) and in due course the quotation would be reported back over the telephone. This resulted in delay and caused serious traffic congestion upon the floor. To cure this situation, the telephone quotation bureau was established. It consists essentially of a distributing switchboard to which the offices of subscribing members are connected by private wire; a number of groups of "quotation operators" seated at tables connected by trunk groups to the distributing board; and a bulletin board for each group of operators, upon which the current bid and asked prices of a number of stocks are posted.

On the Exchange floor are over 100 "quotation boys," each of whom covers one or more stocks; any change in the bid or offer is reported to the bureau by direct telephone line, and the prices shown on the bulletin are changed to correspond. A member desiring a quotation dials a two-digit code (as the distributing board is now machine-switching) which he obtains from a printed booklet containing the names and codes of all listed stocks. A trunk is thus selected which connects the member to the group of operators before whom are posted quotations for the stock in question; he states the name of the stock wanted and receives the quotation.

Many vicissitudes were experienced during the development of this system. No basic engineering data were available. It was known only that the number of daily requests for quotations as determined by actual count upon the Exchange floor amounted to about 8,000 calls per day. Nothing was known as to how this volume might increase upon the introduction of a fast telephone service; holding times, operator's loads, and trunking requirements, could only be guessed at. A safety factor of 300 per cent was finally chosen, and the first bureau was accordingly opened early in 1929 with an estimated capacity of 24,000 calls per day. Suffice it to say that within a few months an entirely new bureau was ordered and before it could be built and placed in service the old bureau was handling 54,000 calls per day.

This new bureau opened last July is expected to take care of 20,000 calls per hour, or 100,000 per day. Incidentally, although this bureau has only about 350 incoming subscribers' lines, this hourly rate of 20,000 calls is greater than that of most major central telephone offices having as many as 10,000 lines each.

Although the new bureau like the new ticker has had little chance to give an account of itself, yet over 9,900 calls have occasionally been handled during 30 minutes.

Some interesting engineering features of the quotation bureau arise from the large number of stocks quoted (about 1,000 active and 350 inactive); the very high calling rate (over 50 calls per line per hour); the extremely short holding time (about seventeen seconds average, of which from six to eight seconds are consumed in dialing alone); and the continually changing concentration of traffic. Within half an hour some stocks are called for hundreds of times; others only once or twice a month. Some stocks which have lain dormant for months may suddenly flare up and as suddenly die, while new stocks may be added on only a few hours' notice. The equipment on the Exchange floor where the all-important information is gathered must be susceptible of uninterrupted rapid use by over 100 people without interfering with the activities of some 3,500 other people who on a busy day are very busy indeed.

Since the introduction of the telephone and electrical ticker into the New York Stock Exchange more than 50 years ago, electric communication systems have grown to be an almost indispensable link in the transaction of its business. As has been shown, the equipment making up these systems must meet the exacting requirements of fast, continuous, and dependable operation, since a failure or delay in any part would result in impeding if not completely interrupting the activities of some of the members. With the growth of the Exchange these systems have grown steadily and undoubtedly will continue to improve and expand according to the dictates of a constantly increasing volume of business.

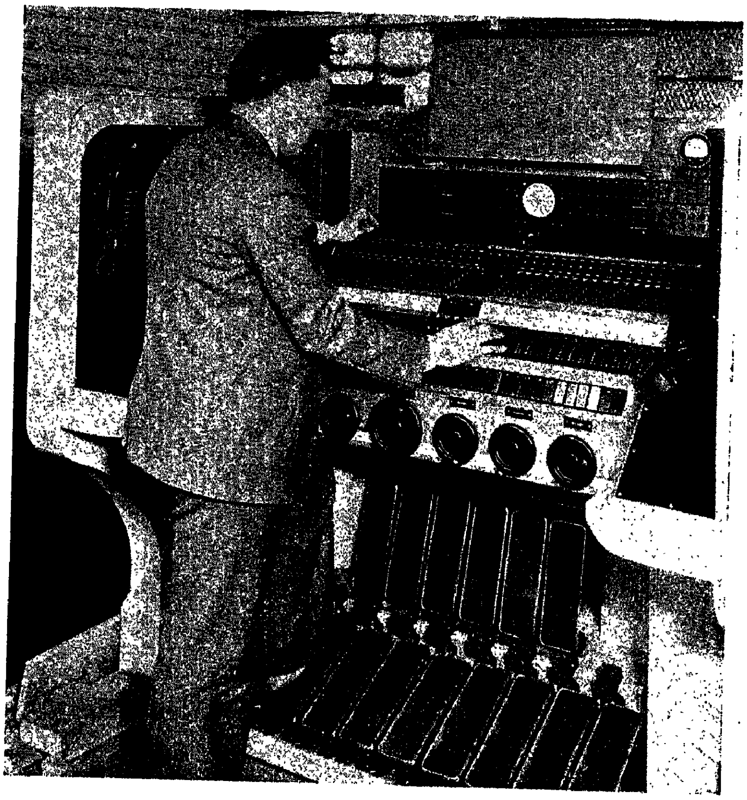
Color Console For Theater Lighting



Front of color console showing arrangement of controls

BY MEANS of vacuum tubes, a "light artist" at the "color console" of Cleveland's Severance Memorial Hall has hue and intensity of auditorium and stage lighting at his finger and toe tips, just as a pipe organist finds pitch and volume of sound at his command.

This unique Westinghouse lighting switchboard, built into an ordinary organ console, has the ability to "remember;" four complete scenes may be set up in advance to be called forth at will by throwing a master switch. The different scenes can form a continuous program, one scene automatically merging into the other at controlled rates. The vacuum-tube control scheme is the means of reaching for the first time the long sought goal of "proportional dimming"—that is, previously-set intensities of various groups of lamps keep their same relative brilliance while being dimmed. However, the operator at his console has every lighting effect subject to his will at all times.

Hitherto, theater-lighting switchboards have lurked in the wings, because they were too ugly and cumbersome to be placed in more desirable locations; a new means of governing the grids of vacuum tubes enabled engineers to concentrate the "nerve centers" of nearly 4,000 lighting combinations in an ordinary organ console. Such a console is portable, a 40-ft. extension cord allowing it to remain on the stage or ride the elevator platform in the orchestra pit.

This "light console" has 36 main-control drums which project ¾ in. above the face of its keyboard panel and are spaced only 15/16 in. apart. These 36 controls brighten or dim a total of 110 lighting circuits.

If the operator needs his hands for other work, or if his fingers tire, a slip of a switch transfers the intensity control to a group of nine horizontal foot-pedals. Four slanting foot pedals can be made master controls for groups of circuits. For instance, by manipulating two of these master pedals half the lights could be dimmed simultaneously while the other half increased in brilliance.

On the diagonal sides of the console are 110-cross-connecting switches for distributing the various circuits among the 36 control panels. Relays in the basement apparatus room do the actual work of connecting the proper vacuum-tube units to their associated apparatus and lamps.

Development Trends in Circuit Interrupters

Several novel circuit interrupting devices are showing possibilities of commercial importance, some representing improvements to oil circuit breakers and others indicating a possible trend toward the non-oil type of equipment. Deion, compressed-gas, expansion, vacuum, and oil breakers are discussed briefly in the light of present laboratory knowledge.

By J. B. MacNeill
Associate A. I. E. E.

Manager, Circuit Breaker Engineering Department
Westinghouse Electric & Manufacturing Company
East Pittsburgh, Pa.

SEVERAL of the many novel ideas for the interruption of high-powered, a-c. short circuits that have been advanced during the last two or three years present attractive features as compared with conventional equipment. Only tests and field service over a period of time can determine the proper place in the electric power industry for each development, since the various ideas presented are too dissimilar to enable the casual observer to form an opinion of relative merits.

At the same time there is a feeling among both the manufacturers and users of high-power circuit breakers that the industry is already too much burdened with complication due to voltage ratings, carrying-capacity ratings, structural arrangements, and many other features more or less special with groups of operating people. It may be conceded that the introduction of radically new forms of circuit-interrupting devices will not automatically simplify present day complication, but unless carefully supervised may only complicate the situation still further.

Generally this problem of circuit-interrupting apparatus is subdivided in two ways: first, into indoor and outdoor apparatus; and second, into low-voltage and high-voltage apparatus. In America, practically all switching equipment above 25 kv. is outdoor, so that a view of the situation is simplified by thinking of the problem in two parts; the first, indoor apparatus at 25 kv. and below, and the second, all outdoor apparatus. The merits of a proposed device to meet the requirements of these two classifications is important in connection with newer ideas.

Deion Circuit Breakers

It is only in the past few years that the cold-cathode arc has been studied, and the theory of current being carried to the cathode by positive ions diffused from a highly thermally-ionized gas layer adjacent to the cathode has been advanced in support of it.[1-4] This conception of a cold-cathode arc has been followed by considerable advance in the rupture of high-voltage circuits in air. Further research investigation[5] disclosed that after a current zero the thin layer of gas immediately adjacent to the cathode regains a rather definite dielectric strength at a rate faster than voltage restored across any practical operating circuit.

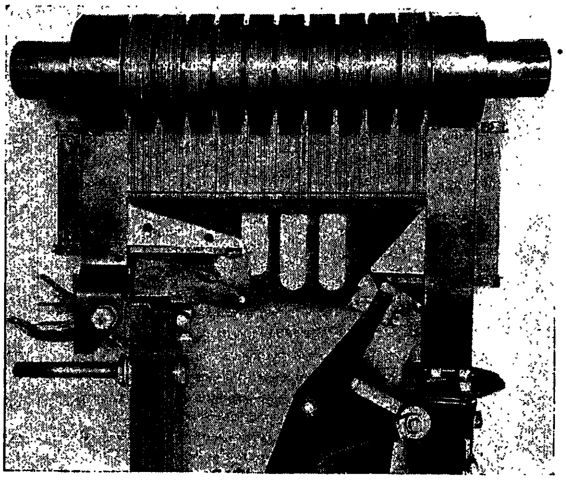


Fig. 1. Partial assembly of a 600-ampere 15-kv. deion air-break circuit breaker designed for 500,000 arc kva.

These ideas of the cold-cathode arc and the relatively high dielectric of the cathode gas layer may be considered in some respects to form the fundamental nucleus of the deion breaker.[6]

Considerable progress has been made in the past year in the development of commercial apparatus involving the deion idea. This work has been based upon laboratory tests[7], and further check by an extensive series of field tests up to 550,000 arc kva. at 12 kv.[8], and other field tests up to 800,000 arc kva. at 24 kv.

A limited number of breakers rated 500,000 arc kva. at 15 kv. has been in 12-kv. service for more than a year without difficulty. A considerable number, approximately 160 pole units, of the same rating has been placed in service during 1930 on from 11 to 13 kv. There are at present under way numerous tests on a breaker for 1,000,000 arc kva. at 15 kv. The plate unit of this breaker is shown in Fig. 2. An improved breaker designed for 1,500,000 arc kva. at 25 kv. has been built and is shown in Fig. 3. Work is well under way on a breaker for 250,000 arc kva. at 5 kv.

From "The Trend in Development of Modern Circuit Interrupters," (No. 31-3), presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

1. For references see bibliography.

By referring to Fig. 2 it is seen that a considerable modification has been made in the plate structure as compared to the older "key" form of plate shown in Fig. 1. In the newer construction each plate is provided with a vent direct from its own arcing space. This vent is much more direct than the older method of venting at the end of the arc-drawing space shown in Fig. 1, and therefore superior heat elimination after short circuit is secured. This in turn increases the rupturing capacity of a given sized plate and the number of operating cycles to which it may be subjected.

The new plate structure eliminates the large blow-in coils previously necessary on the sides of the chamber, thus making arc transfer into the plates easier by reducing complication and eliminating the possibility of voltage puncturing from the coils and magnetic circuits to the opposite polarity inside the chamber. This new design of plate has made possible the building of 25-kv. breakers in a single unit and in a space fairly comparable with 15-kv. designs.

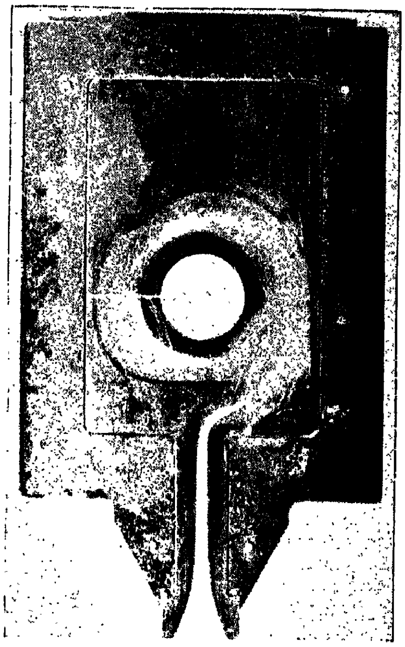

Fig. 2. A deionizing plate from a 1,000,000-kva. deion air-break unit

So far as can be seen there is no immediate limitation to the rupturing capacity of deion air breakers. Like other non-immersed switching devices, however, they are subject to the limitations of present day insulating materials. While development along this line is possible, it seems advisable for the present to limit this type of circuit breaker to 25-kv. service and below, and for the most part to indoor applications. An insulation test of 80 to 100 kv. with a breaker open or closed can be secured with reasonable construction for 25-kv. service. If atmospheric conditions are normally good, this appears sufficient giving a relatively small deposit of dirt and moisture.

COMPRESSED GAS CIRCUIT BREAKER

The idea of using compressed gas for interrupting high-voltage circuits is not new and has been worked on by several concerns. However, with the aid of adequate test facilities, the A. E. G. of Germany has sponsored this development and much progress has been made. Several technical papers by the inventors and designers of this equipment have been presented to the industry.[9] Fig. 4 shows the design of this breaker for 10-kv. service. The high-voltage circuit is made at the top of the tube through a terminal which is connected by the moving contact to the lower terminal at the bottom end of the tube. Operation is generally secured by an air cylinder fed from the same source of air pressure which gives arc rupture, and the mechanical operation of the device is so arranged that movement of contact parts and valve actions assure air pressure simultaneously with, or just previous to, the parting of contacts. There is thus no possibility of drawing a high-voltage arc without necessary pressure for rupture being present. For the purpose of assuring several repeated operations without the necessity of air from the main storage, the pressure in the air reservoir at the breaker is generally quite high. It is reported that in a typical case, an air pressure of 15 atmospheres (225 lb.) is reduced to 11 atmospheres after the first short circuit, 7 atmospheres after the second short circuit, and approximately 4 atmospheres after the third short circuit. An initial pressure of approximately 7 atmospheres is adequate, therefore, provided the pressure can be renewed after each short circuit.

The compressed-gas breaker has the advantage of an adequate supply of arc-extinguishing gas immediately available when the arc is started. It is extremely clean in operation with no liquids to be spilled and no large deposits, such as carbon, to be cleaned from contact parts. Furthermore, it seems to operate with low arc energy, and due to the use of special contact materials the depreciation of these parts is small.

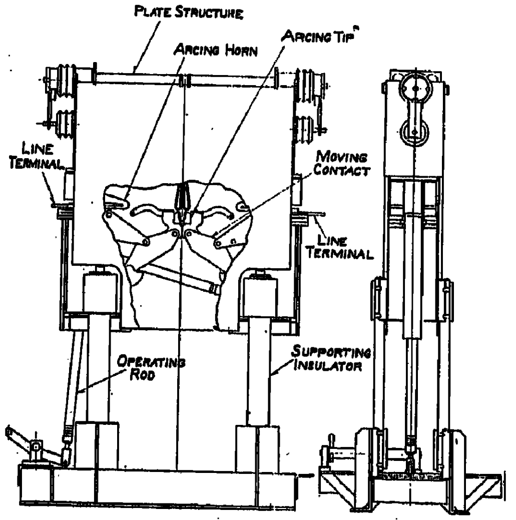

Fig. 3. Outline of single-pole unit for 1,500,000-kva. (arc) 25-kv. deion air-break circuit breaker

This device has the disadvantage of requiring at all times clean, dry air under pressure ready for instant use even though under service conditions the breaker may not operate for days or perhaps weeks. The use of air in train control where apparatus is inspected frequently and operated many times daily has reached a stage of high efficiency in this country, but the use of air valves where their operation is only infrequent has not been altogether favorable. The use of porcelain insulators subjected to sudden blasts of gas pressure may present some difficulty, and the possibility of moisture in the air affecting insulation value has to be reckoned with. The insulating limitations are similar to those of other non-immersed devices, and applications on indoor and relatively low-voltage lines present less hazard than do those for outdoor or higher voltages.

On the whole, the development of this device is a noteworthy engineering achievement and it will doubtless assume some commercial importance in the voltage classes for which it is best suited.

EXPANSION BREAKER

The development of a live-pot circuit interrupter using water is being sponsored by the Siemens-Schuckertwerke of Germany.[10] A breaker for 10-kv. service is shown in Fig. 5. A considerable number of these breakers is being manufactured for 6- and 10-kv. service, and some with ratings up to 500,000 arc kva. have been placed in successful operation in Germany during the past year.

The principle of arc interruption underlying the device is expressed in the following formula:

$$-\frac{dT}{dt} - K\frac{dV}{dt} > 0$$

Here T is the absolute temperature of the vapor in the arcing space, V is the instantaneous value of the restored voltage, and K is a value constant for a given fluid and pressure but varying with these factors. This formula states that the rate of temperature decrease must be greater than the value obtained from a constant multiplied by the rate at which voltage appears across the contacts after the current has become zero. In accordance with one possible theory offered in explanation of arc extinction, this decrease in temperature is accompanied by a corresponding condensation of moisture on the electrons, thereby increasing their inertia and making impossible a breakdown of the space between the contacts.

Fig. 5 shows a breaker of three pole units, each having a chamber mounted on a porcelain column. Above each chamber there is a triangular, hooded structure containing an operating mechanism mounted upon another column of insulating material. This unit is of the single-break-per-pole type and the moving contact operated by the rod in the rear is shown protruding from the operating mechanism chamber.

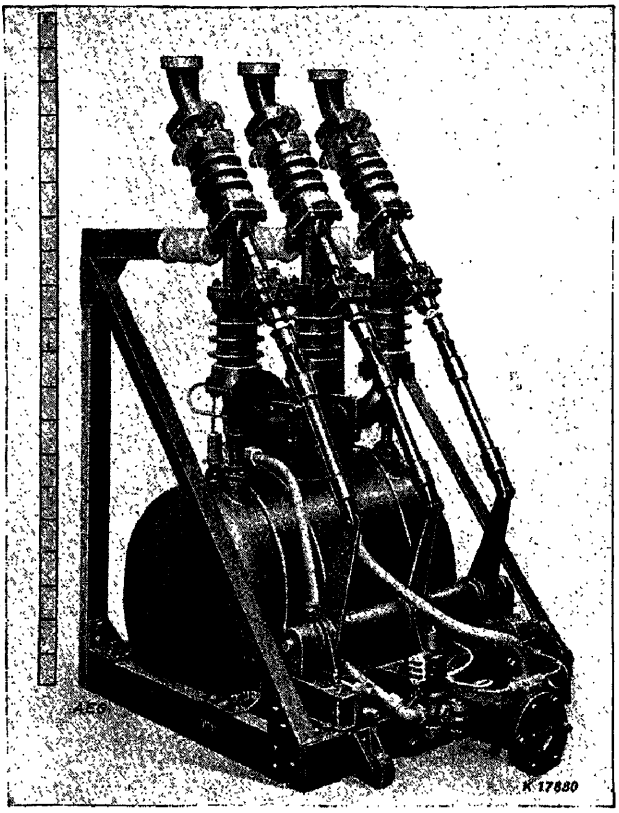

Fig. 4. Three-pole, pneumatically-operated, 600-ampere, 10-kv. breaker

The fluid chamber is divided into two parts, the inner chamber being filled with water or other liquid, and the outer chamber being a water storage space and air space to allow rapid expansion of the gas when it passes through the throat bushing of the inner chamber. Vent pipes from the outer chamber are provided for leading the expanded, moist gases safely away from the vicinity of the arc-rupturing space.

Arc interruption is secured by adiabatic expansion of the gases through the throat bushing into the outer chamber. This action causes the temperature decrease and corresponding moisture condensation in the arc stream, which in turn reduce movement of the electrons and increase the dielectric strength of the arc path.

In 1921 L. C. Nicholson developed a device similar to the expansion breaker which successfully interrupted short circuits up to 6,000 amperes at 66 kv. on a single-pole unit on the lines of the Niagara Lockport & Ontario system. Mr. Nicholson's device differed radically, however, from the expansion breaker, in that it depended upon extremely high speeds of mechanical movement for proper circuit rupture.

The engineering development of this expansion breaker has been very ingenious and many of the difficulties confronting it at the beginning have been removed. The use of water instead of oil seems to be feasible—at least for low voltages—and evaporation is not excessive. For low operating temperatures, the mixture of some compound such as glycerine with the water is necessary and apparently permissible. The question of contacts for large current capacities necessarily complicates the design but the difficulties are not insurmountable.

Since the rate of gas expansion depends upon the throat area, the design of the throat parts requires much work in order that proper deionizing action will occur over the whole range of currents and with different circuit voltage conditions. In the past, difficulty of this nature has been encountered with devices having similar characteristics; the designers feel that these problems have been successfully solved. The possibilities of explosive gas formations caused by breakdown of water into hydrogen and oxygen have been investigated and no dangerous conditions found. Naturally a device of this kind possessing the general insulation limitations of non-immersed apparatus is more suitable for lower voltages and for use indoors than for outdoors. An interesting feature of the design is the air-gap between the expansion chamber and moving contact when the breaker is open; in some cases the designers feel this may obviate the necessity of disconnecting switches, although of course it would be unwise to work on the breaker structure without such safety provision.

VACUUM BREAKERS

In general, the present indications are that while a properly constructed vacuum circuit interrupter would give a high grade of rupturing performance when interrupting low-current circuits, and may handle high voltages with very small contact separation, a material advance in vacuum technique will be necessary before this device can be developed to the point of dependable operation on high-power circuits, such as are encountered in present day switching service. At the moment, in spite of the large amount of intelligent development work done on the idea, the vacuum circuit breaker has no commercial importance.

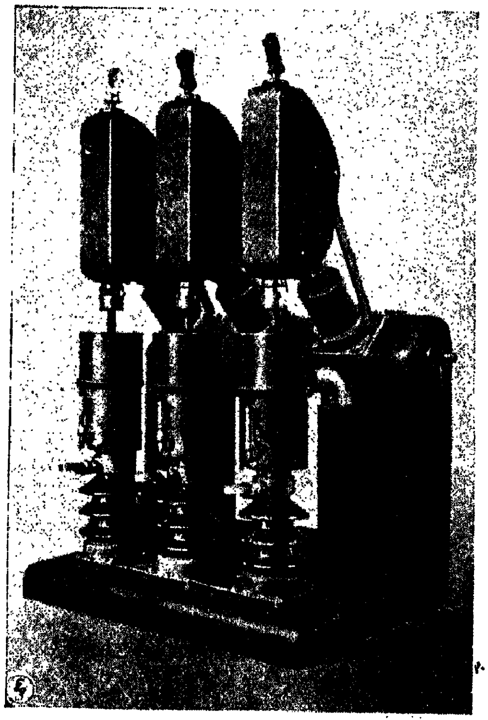

Fig. 5. Three-pole, electrically-operated, 600-ampere, 10-kv., 400,000-kva. (arc) expansion breaker

GENERAL COMMENTS ON OIL-LESS BREAKERS

In studying the work that has been done on breakers not using oil, one is forcibly impressed with the great ingenuity that has been necessary to overcome the troubles encountered. Insulation and voltage distribution quite low in the voltage range sometimes become serious questions. At times the ability of an oil insulating medium to erase broken-down arc trails, to absorb large amounts of energy by volatilization of a small amount of liquid, and to close in and cool off immediately all necessary parts, is sadly missed.

Modern non-oil devices as a whole are characterized by reduced arc energy, increased speed of switch operation, and improved contact materials. These all tend toward quieter and more satisfactory performance under short circuit, and reduced maintenance. Highly scientific work has been possible with modern facilities for test and demonstration of theories. Undoubtedly much more is known of principles of arc rupture as a result of this work.

OIL BREAKER DEVELOPMENT

It is only natural that high-power testing equipment now available to several large manufacturers should influence the design of oil breakers as well as that of oil-less breakers. Much improvement has been made along the lines of reduced arc energy, reduced arcing time, and a lower over-all switching time. Field tests have shown complete circuit-breaker operation of from six to eight cycles for 220-kv. systems, and from five to six cycles for lower-voltage systems, from the instant relay contacts are closed until the short circuit is extinguished. This performance is accompanied by arc energy constituting a fraction of that resulting with older breakers, with consequently reduced maintenance as well as assurance of adequate rupturing ability.

Advances in design continue to be reported by manufacturers of oil circuit breakers using widely different interrupting devices including multiple breaks, high-speed contacts, explosion chambers, and deion grids, and in some cases special arrangements of magnetic blowout. The limitations of all these devices have not been reached, but given similar performance in the way of high-speed action, reduced arc energy, and physical demonstration due to gas pressure, there is an inclination to favor the simpler devices as requiring less maintenance.

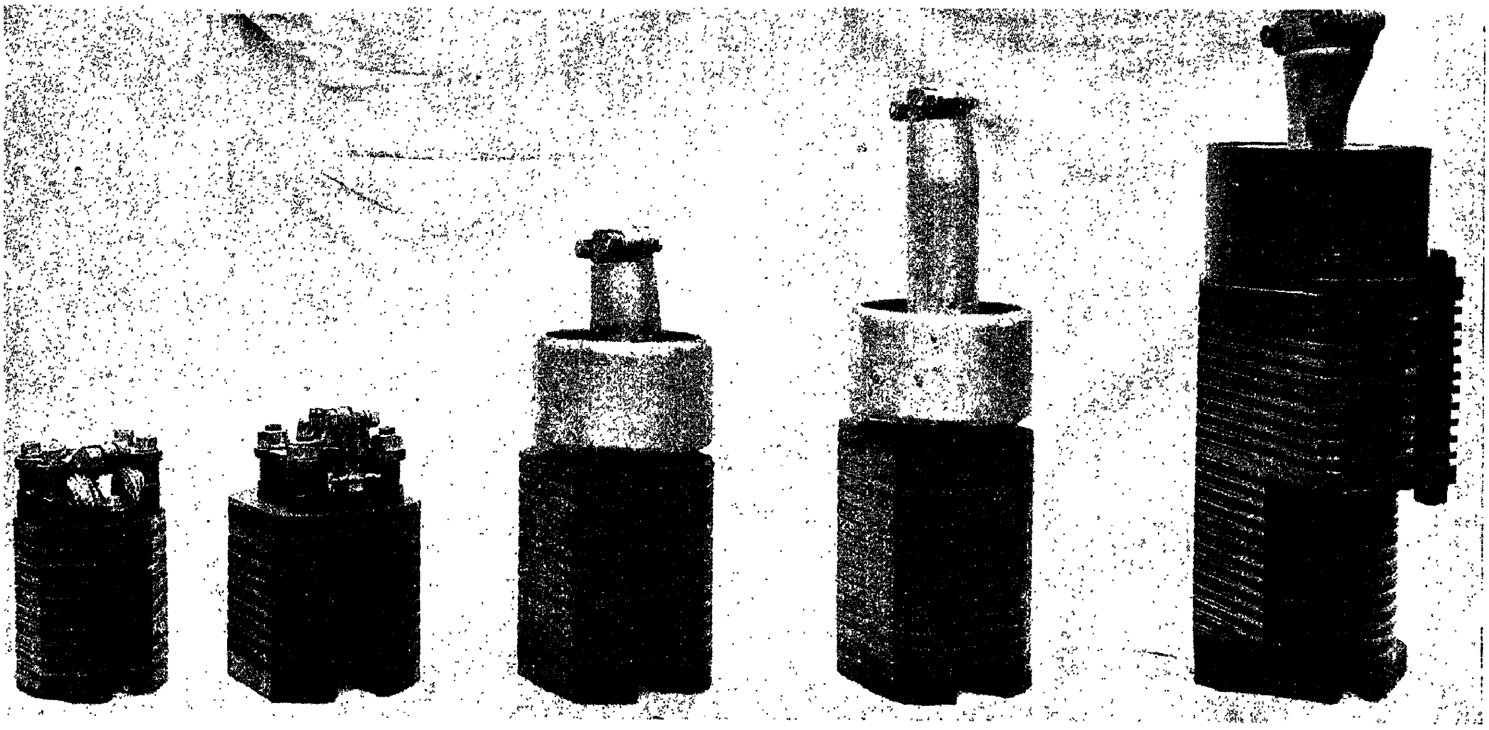

Fig. 6. Deion grid assemblies (from left to right) for installation in 34.5-46-kv., 69-92-kv., 115-kv., 138-kv., and 230-kv. oil circuit breakers

DEION GRIDS

A year ago this device was new and its preliminary development was reported.[13,14] At that time, practically no operating experience was available and results of certain important field tests were just being received. A broad commercial development of this idea has occurred in the past year and the deion grid may now be obtained as standard equipment for breakers of all voltages above 25 kv. and for interrupting capacities up to 2,500,000 arc kva.

The effect of powerful magnetic fields on the arc in oil breakers had been known for some time[1] and commercial apparatus for high-speed operation giving ½ cycle of arcing over a wide range of current from 2,000 amperes upwards at 12 kv. has been placed in service. Analysis of these results in the light of recent fundamental arc research showed that powerful deionizing action was at work. The blowout action of the magnetic field by extending the arc rapidly outward was maintaining it in intimate contact with fresh oil, and the gas generated by this contact between oil and the intense heat of the arc was unusually effective. This continual introduction of fresh un-ionized gas into the arc stream resulted in a high rate of deionization not possible by diffusion of ions into gases playing around the periphery of the arc. The arc path naturally regained sufficient dielectric strength to withstand restored voltage in a short time. This idea held hope of improvement in high-voltage breakers provided a proper physical application of the idea could be made. Ordinary blowout devices consisting of large coils and pole faces are not adapted for extremely high-voltage work, as the attendant problem of proper insulation is practically insoluble.

The use of oil in high-voltage breakers, however, presents a great advantage; the necessity for moving the arc terminals considerable distances from the original arc-drawing surfaces to scavenge the area between contacts did not exist. It was necessary only to develop means for utilizing the natural mobility of the arc and the inherent immobility of the oil while maintaining intimate contact between them, and to provide that the gas generated should pass effectively through the arc stream for deionizing purposes. This advantage was found in the deion grid, which provides a magnetic field to move the arc along a confined path as well as means for solidly entrapping the oil in this path with proper provision for gas escapement through the arc. Fig. 6 shows a number of these grids of various sizes suitable for a wide variety of operating voltages.

The introduction of the deion grid has been accompanied with intensive laboratory and field testing work, so that its performance has been carefully measured and its fundamental principles thoroughly understood. There is, therefore, assurance of satisfactory operation not procurable in the past, with novel devices for circuit interruption.

Performance of all sizes of deion grid is fairly comparable. For average circuits, 10 kv. can be opened per inch of break distance on a single break per pole and 20 kv. per inch of lift-rod movement on the conventional breaker having two breaks per pole. In the average case, arc energy is reduced to approximately 7 to 10 per cent of that obtained with usual open-break devices.

Conclusions

An analysis of circuit rupturing ideas now before the industry justifies the following conclusions:

1. Several ingenious and rather well-developed devices which do not use oil as a rupturing medium are fast becoming available for commercial use.
2. All these devices, while possessing good arc-rupturing characteristics, are subject to the limitations of available insulating materials. Their application to high-voltage systems makes difficult the problem of coordinating the impulse values of lines and apparatus.
3. For reasons of insulation and difficulty of operation in unfavorable locations, conservative engineering would seem to limit the use of these non-oil-filled breakers to voltages of 25 kv. and below, and for the most part to indoor service.
4. Other things being equal, preference will naturally be extended to that form of non-oil circuit interrupter requiring no arc-rupturing medium, whether such medium be compressed gas, liquid, or vacuum.
5. Improvements have been made in oil circuit breaker design which assist system stability, reduce arc energy, and contact wear and breaker maintenance.
6. To secure coordination of apparatus and line insulation on large systems, the growing requirements for ample insulation factors on high-voltage circuit breakers, after, as well as before, rupturing duty has been performed, makes the use of oil in circuit interrupters extremely desirable for ratings above 25 kv., especially in outdoor service.

Portable Substation for Emergency Industrial Use

As an outgrowth of its railway-car portable substations the Duke Power Company, Charlotte, N. C., is using four of these 1,320-kva., 44-10/2.4 & 0.6-kv. trailer-mounted portables to back up the service of its 225 industrial substations. Total service weight is 21,400 lb., 1,400 lb. more than the legal highway limit, necessitating the withdrawal of five drums of oil before moving the equipment over a state highway —a condition, however, which expedites a necessary inspection of the terminal board and provides a load for the pulling truck thereby increasing its traction. The trailer may be handled from either end.

Current Collection in Hydrogen Atmosphere

Test runs of commutators and slip-rings operating in hydrogen gas reveal interesting characteristics and lead to five definite conclusions.

By R. M. Baker

Westinghouse Electric & Manufacturing Company
East Pittsburgh, Pa.

THE FIRST electrical machine to be operated in hydrogen was the synchronous condenser, chosen largely because of the ease with which it could be covered by a gas-tight housing. Probably the next advance will be the application of a direct-connected exciter to one of these machines and that will require the exciter to be operated in hydrogen. If it is proved that commutation can be accomplished satisfactorily in hydrogen it may not be long before the hydrogen-cooled synchronous converter will make its appearance; therefore it would seem that much depends upon the accumulation of knowledge on the general subject of commutation and current collection in hydrogen. It represents a field which until just recently had received no attention. Whether or not there will arise any new and serious difficulties remains yet to be seen.

This paper is not intended as a complete treatise of the subject but only as a beginning. It describes a few tests made on commutator machines and slip-rings running in hydrogen which although not extensive establish a few facts quite conclusively.

Commutation Tests

Upon starting each new test it was necessary to pass considerable hydrogen through the tank to wash out the air, but after a good hydrogen purity was once established it was sufficient merely to maintain a small positive pressure in the tank.

Table I gives the results of five brush-life tests made on a short-circuited generator. All tests were made with full-load current in the brushes, but the generator was not always adjusted for the same grade of commutation. Tests Nos. 1, 2, 3 and 4 were made with 30 per cent of the current shunted from the commutating-pole winding of the generator. The sparking at the trailing edge of the brushes was quite severe and even under the most favorable conditions naturally resulted in rather short brush life. Test No. 5 was made with almost sparkless commutation.

TABLE I—CALCULATED BRUSH LIFE OF GENERATOR BRUSHES

Test No.	Duration of test—days	Atmosphere	Calculated brush life in days			
			Brush No. 1	Brush No. 2	Brush No. 3	Brush No. 4
1	15.0	Air	588.0	229.0	812.0	362.0
2	6.41	Hydrogen	94.4	9.2	128.0	10.6
3	6.78	“	222.0	205.0	282.0	161.0
4	7.0	“	43.7	59.9	69.3	45.0
5	15.0	“	1875.0	1770.0	2000.0	2310.0

Brush life is calculated on the assumption of one inch allowable brush wear. Brushes Nos. 2 and 4 are the two positive brushes of the generator and are on opposite brush arms.

The most interesting comparison is that between tests Nos. 1 and 2, which were made under identical conditions except that the former was made in air and the latter in hydrogen. In air the minimum calculated brush life was almost a year whereas in hydrogen it was only a little more than a week. Furthermore the damage to the commutator during the test in hydrogen was appreciable. The trailing edges of the commutator bars were burned away, in some cases as much as 1/32 in., leaving a bright metallic surface. This first test in hydrogen was quite unique in that it showed such a great difference in wear between the positive and negative brushes. Both tests described were made before a hygrometer was installed and consequently the relative humidity of the medium in which they were run is not known. It is very likely, however, that the test in hydrogen was started with a relative humidity of about 50 per cent and ended with a relative humidity of about 20 per cent.

Effect of Humidity

Tests Nos. 3 and 4 were made for the purpose of determining whether or not the unusually bad behavior of the brushes and the commutator in test No. 2 could be attributed to the high relative humidity which was suspected during this test. These tests were made with 30 per cent of the current shunted from the commutating-pole winding of the generator and the only difference in the two tests was in the relative humidity of the hydrogen atmosphere in which they were run. During test No. 3 the relative humidity was maintained at less than 10 per cent, whereas during test No. 4 the relative humidity was maintained practically constant at 50 per cent. Table I shows that the wear at the higher humidity was approximately four times as great as it was at the lower humidity. An inspection of the

---

From "Commutation and Current Collection in Hydrogen," (No. 31-36) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

commutator gave further evidence of improved performance during the low-humidity test.

Upon shutting down test No. 3 the commutator appeared dark and uniformly smutted, but apparently no damage had been done. A light application of fine sand paper showed the commutator to be in perfect condition. This however was not true of the commutator at the end of test No. 4. It was apparent immediately upon shutting down this test, that the commutator had been badly burned. The bright copper was showing on the trailing edge of the commutator bars just as it was after test No. 2, and the roughness could not be removed by any reasonable amount of sanding.

It is interesting to note that brushes Nos. 1 and 4 which were on the side of the machine nearest the moisture supply, showed somewhat shorter life than brushes Nos. 2 and 3 which were on the other side of the machine. In conclusion it may be said that if a commutator machine is running in hydrogen and sparking badly, the presence of moisture is detrimental to both the brushes and the commutator.

So far, all the tests described were made with the generator adjusted to give severe sparking at the brushes, the idea being to determine what would happen if this condition should arise in service. To show that operation in hydrogen may be quite satisfactory when commutating conditions are normal it only is necessary to refer to test No. 5, the results of which are tabulated in the last line of Table I. This test was made while the generator was delivering full-load current, but the shunt had been removed from the commutating-pole winding. The minimum brush life of almost five years and the good condition of the commutator at the end of this test would seem to indicate that as long as a machine is designed and adjusted for good commutation in air, it will behave quite satisfactorily in hydrogen. This last test was repeated several times and the same good results were always obtained.

SLIP-RING TESTS

The apparatus used in these tests consisted of a collector or set of slip-rings driven by an adjustable-speed d-c. motor and so arranged that the space around the rings and motor could be filled with hydrogen. Each ring was $\frac{7}{8}$ in. wide and $9\frac{1}{2}$ in. in diameter and was trimmed with one brush $\frac{5}{8}$ in. wide by $1\frac{3}{4}$ in. thick by 2 in. long. Direct current was supplied to the brushes and rings by an arc-welding set. Leads brought out through the bed-plate made it possible to measure the contact drop of any brush. Most of the tests were made with a current density of about 40 amperes per sq. in. and a peripheral ring speed of 2,500 ft. per min.

The first tests were made on a tool-steel ring trimmed with different grades of carbon and graphite brushes. The results of these tests were always the same. Lumps of hard material, sometimes 0.02 or 0.03 in. in diameter, were formed in the brush face and immediately began to score the ring. Upon analysis the hard material proved to be cementite (Fe_3C) which apparently had been formed by a direct combination of iron and carbon in the presence of localized high temperatures in the contact. In an attempt to prevent the formation of hard spots in the brush face, a helical groove was cut in the face of the tool-steel ring. With this change it was found that several brush grades which failed on the plain ring could be operated without difficulty; the formation of hard particles in the brush face was eliminated and the ring acquired a good polish.

These tests were quite similar to those made on the tool-steel ring and again the results were almost independent of the grade of brush used. When the air surrounding the rings was replaced by hydrogen all grades of carbon and graphite brushes showed a marked decrease in contact drop; in fact, the ratio of air to hydrogen was usually greater than ten to one. For most grades of brushes this reduction was permanent, although other grades after running for a while began to smut the ring; when this occurred the contact drop increased to about the same value as it would have in air.

No attempt will be made to explain the phenomenon disclosed by the above tests, but it was noticed that the results were peculiar to the particular brass ring on which the tests were made. Similar tests were made on the brass ring of another test set and it was impossible to even approach the low values of contact drop obtained in the first brass-ring tests. The only explanation which could be found for this disagreement in behaviour was the difference in the compositions of the two brass rings. This would also explain the fact that in the earlier tests the steel slip-ring showed only a slight decrease in contact drop when hydrogen was introduced.

CONCLUSIONS

It is realized that the tests reported in this paper are not very complete, but from the results of the tests described the following tentative conclusions may be drawn:

1. A commutator machine designed and adjusted for good commutation in air will operate satisfactorily and give good brush life in hydrogen.
2. If a commutator machine must spark in hydrogen the brush life may be increased many times by keeping the relative humidity below 10 per cent. This will also prevent damage to the commutator.
3. The contact resistance of carbon brushes on a commutator may be materially lowered by the introduction of hydrogen.
4. Carbon or graphite brushes cannot be operated satisfactorily on plain tool-steel slip-rings running in hydrogen.
5. The contact drop between a carbon or graphite brush and brass slip-ring may be ten times as high when th ring is running in air as when it is running in hydrogen.

Evolving a Modern Protective Relay System

The history of a decade of experience with various kinds of protective relay equipment on one of the nation's largest electric service systems is outlined here. Conclusions leading to, and methods of accomplishing, a complete revision in system operating practise are discussed.

By E. R. Stauffacher

Member, A. I. E. E.

Southern California Edison Company, Ltd.,
Los Angeles, California

PROTECTIVE RELAYS make possible a continuity of electric service under conditions which would have rendered such service impossible as little as ten years ago. Further, these sensitive devices permit improvements in transmission efficiency through enabling the safe use of lines in parallel with consequent reduction in $I^2 R$ loss, even though one line might have sufficient capacity to accommodate the load.

Previous to 1923 when the 150-kv. lines of the Southern California Edison Company, Ltd., were changed to 220-kv., no protective relays were employed. When a fault appeared the generator voltage was lowered and then gradually built up until the fault arc broke and ground currents ceased to flow. These faults resulted in service interruptions which could not be tolerated when the lines were changed over to the higher voltage. The decision was made therefore to install some form of relay protection. Phase relays of the induction type were so connected that two lines at a generating or substation were balanced against each other, both being under automatic protection. If it became necessary to remove one line of a pair from service, however, the other had to be made non-automatic, in which case the old scheme of reducing the generator voltage had to be relied upon. This plan while a great improvement over the older system of entirely non-automatic operation, was far from ideal, and the need for further improvement soon became apparent.

The first modification was in the form of balanced ground relays, similar to the phase relays already in service but designed to operate at lower-current values. This addition speeded up the clearing of heavy faults considerably, and provided further for the removal of faulty sections of line from the system when the ground current was too light to operate the phase relays.

With this combination of balanced phase and ground relays most faults were cleared without interruption to service; however, some interruptions still occurred when operating one line non-automatic, a practise still employed when one line of a balanced pair was out of service. Also, in a few cases when faults occurred during heavy-load periods the two ends of the system even after the fault had been cleared would sometimes drop out of step. This situation led to the installation of oscillographs and curve-drawing instruments several generating plants and substations to record transient conditions resulting from a fault. A study of records so obtained indicated a necessity for clearing the faults in a shorter time, limiting the ground current to as small a value as practicable, quick response of generator field excitation, and additional transmission line, only two 220-kv. lines then being in operation.

PROTECTIVE RELAY INSTALLATIONS—220-KV. SYSTEM

Table I shows the number of flashovers and other troubles on the 220-kv. transmission system from 1924 to June 1930. A study of the operating records from which this table was prepared demonstrated that at no time has there been any transient fault which has not been accompanied by a flow of some ground current. The wide spacing of conductors at this high voltage is responsible no doubt for the fact that the likelihood of phase-to-phase faults without a fault current to ground is rather remote. As a result of this situation, the practise of the past few years has been to abandon entirely the use of phase relays, depending solely upon ground or residual relays for protection.

TABLE I—220-KV. INTERRUPTIONS

Year	Number of faults	Faults cleared correctly	Number of times relays not in at time of fault	*System interruptions	Percentage system interruptions to faults

Where two or more lines are connected to a generating plant or substation these lines are protected by induction, current-balanced relays connected in the residual connection of the bushing current transformers mounted

---

From "Development of a Relay Protective System" (**No. 30-191**), presented at the A. I. E. E. Pacific Coast convention, Portland, Ore., Sept. 2-5, 1930, and subsequently made available for publication.

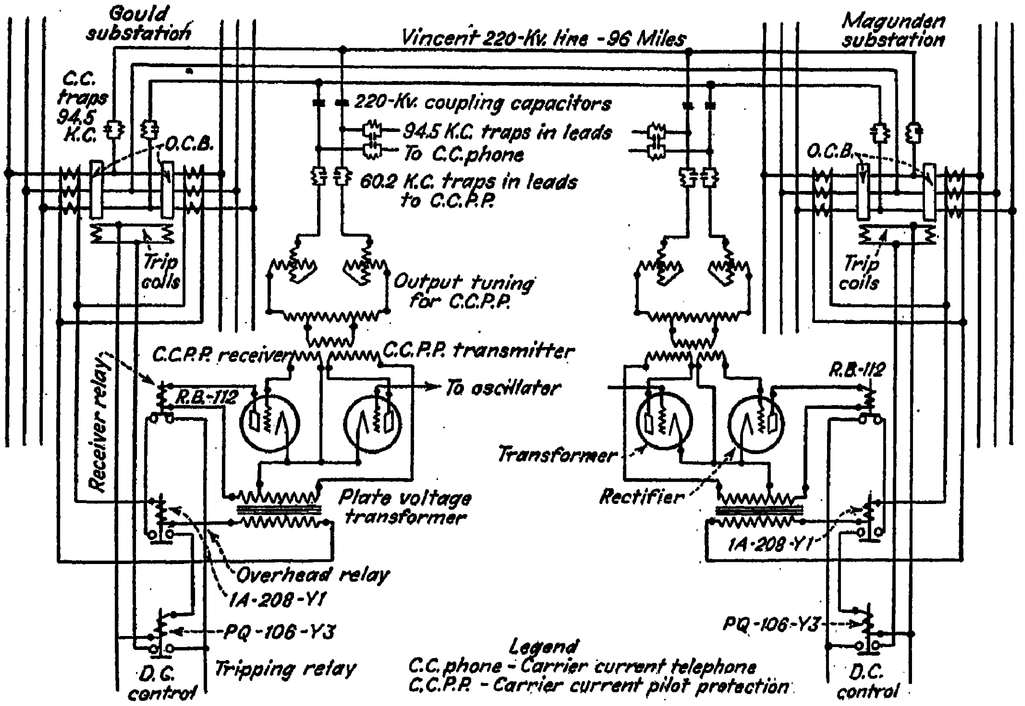
in the high-voltage oil circuit breakers. The relay scheme for single-line operation was changed to provide protection for a single line by means of residual directional relays actuated from the residual connection of the current transformers in the breakers and in the neutral or the residual connection of the station transformers.

The question of testing protective relays on important transmission lines has been a problem always, since to make an over-all test of the relays with the oil circuit breaker necessitated that a line be removed from service or be made non-automatic during the test. There have been a few cases of trouble when a section of line was operating non-automatic for relay testing. As a result it was decided to eliminate the possibility of an interruption from this source by installing duplicate sets of residual relays for each line, thus providing relays for each of the two oil circuit breakers controlling a line. This permits the testing of one set of relays with its oil circuit breaker, leaving the line under adequate protection with the remaining set of relays and oil circuit breaker. This latest scheme of protection completed in 1930 has been installed throughout the full length of the 220-kv. transmission system.

As a result of different routing and different substation connections, the company's third (Vincent) line between Los Angeles and the Big Creek plants has a current distribution somewhat different from the two other lines, and it has always been a problem to provide it with proper protection with the current-balanced relays which were satisfactory for the two original lines. The two terminals of one of the two sections of this line are switching stations not provided with any means of obtaining potential from the 220-kv. transmission line, and for this reason it was not possible to provide protection with power-directional relays. As a result of this condition, the carrier-current pilot protection was installed on the 96-mi. Gould-Magunden section of the 220-kv. Vincent transmission line and has been in service for nearly two years.

The carrier-current system is similar to the other forms of protection now in use on the 220-kv. system in that it provides for line-to-ground short-circuit protection only. It may be compared to the pilot-wire relay circuit, since the same net results are obtained. However, an exchange of relay-actuating current does not occur with the carrier system which operates instead to compare the direction of the two instantaneous residual currents at each end of the section of line affected. If the instantaneous residual current is in phase (in the same direction) indicating that a fault is external to the section protected, the equipment operates to lock out and prevent the induction overcurrent relays from tripping the oil circuit breakers. However, if the fault is in the section of line under carrier protection, current will flow towards the fault from the energy sources at each end of the section and the currents at the two ends will be approximately 180 deg. out of phase with each other. Under these conditions a fault within the section is indicated and the carrier-current receiver at each end is rendered automatically inoperative, permitting the induction overcurrent relays to function at both ends to clear that faulty section from the system.

Table II gives a summary of the results obtained with this protective equipment. When it is considered that the carrier-current system is an innovation in protective schemes, and that a great many problems had to be worked out before it was manufactured and installed, the results have been quite satisfactory. At each of



Schematic diagram indicating equipment and method involved in using carrier-current pilot protection system on a 96-mile section of 220-kv. transmission line

the two switching stations the section of the 220-kv. line so protected terminates in a set of two oil circuit breakers which connect to the two high-voltage buses at each station. Coupling between the 220-kv. Vincent line and the carrier-current pilot protection is obtained by means of oil-filled coupling capacitors connected to two of the three phase wires each connected from line to ground, giving what is termed "interphase" coupling. This coupling is made to the same phase wires at each end of the section protected, and the same set of capacitors is utilized for transmission of both the relay carrier frequency and the telephone carrier frequency over the same transmission line. Between the coupling capacitors and the 220-kv. oil circuit breakers at each station are installed carrier-current frequency traps built similar to a large choke coil and having a capacity of 800 amperes continuous duty with an inductance of approximately 70 microhenrys. Because of the double use of the capacitors, it is necessary to filter the protection carrier frequency and the communication carrier frequency into their proper channels.

TABLE II—SUMMARY OF OPERATION OF CARRIER-CURRENT PILOT PROTECTION ON A 96-MI. SECTION OF 220-KV. LINE

Total cases of trouble since carrier-current pilot protection installed..	28
Cases of trouble exterior to section..	20
Cases of trouble within section..	8
Correct operations..	26
Incorrect operations..	2

The relatively heavy volt-ampere burden placed upon the bushing current transformers by the carrier equipment and the necessity of exciting that equipment from the secondaries of these transformers requires that to operate the equipment the fault current be 320 amperes or more. This rather high setting has been satisfactory, but if practicable it would be desirable to obtain a setting of from 200 to 250 amperes. Studies and experiments by the manufacturers now are under way which give promise of obtaining certain characteristics permitting the lower setting to be used. The overcurrent induction-type relay which is used is designed to operate at unusually high speed. To obtain for the carrier protection the greatest speed of operation consistent with a reasonable life of vacuum tubes, the filaments of all tubes are operated at approximately full voltage, but with no excitation on the plates. Experience indicates a necessity for making a transmission check of the equipment at frequent intervals, and provision to do this every two weeks has been made.

66-Kv. System Protection

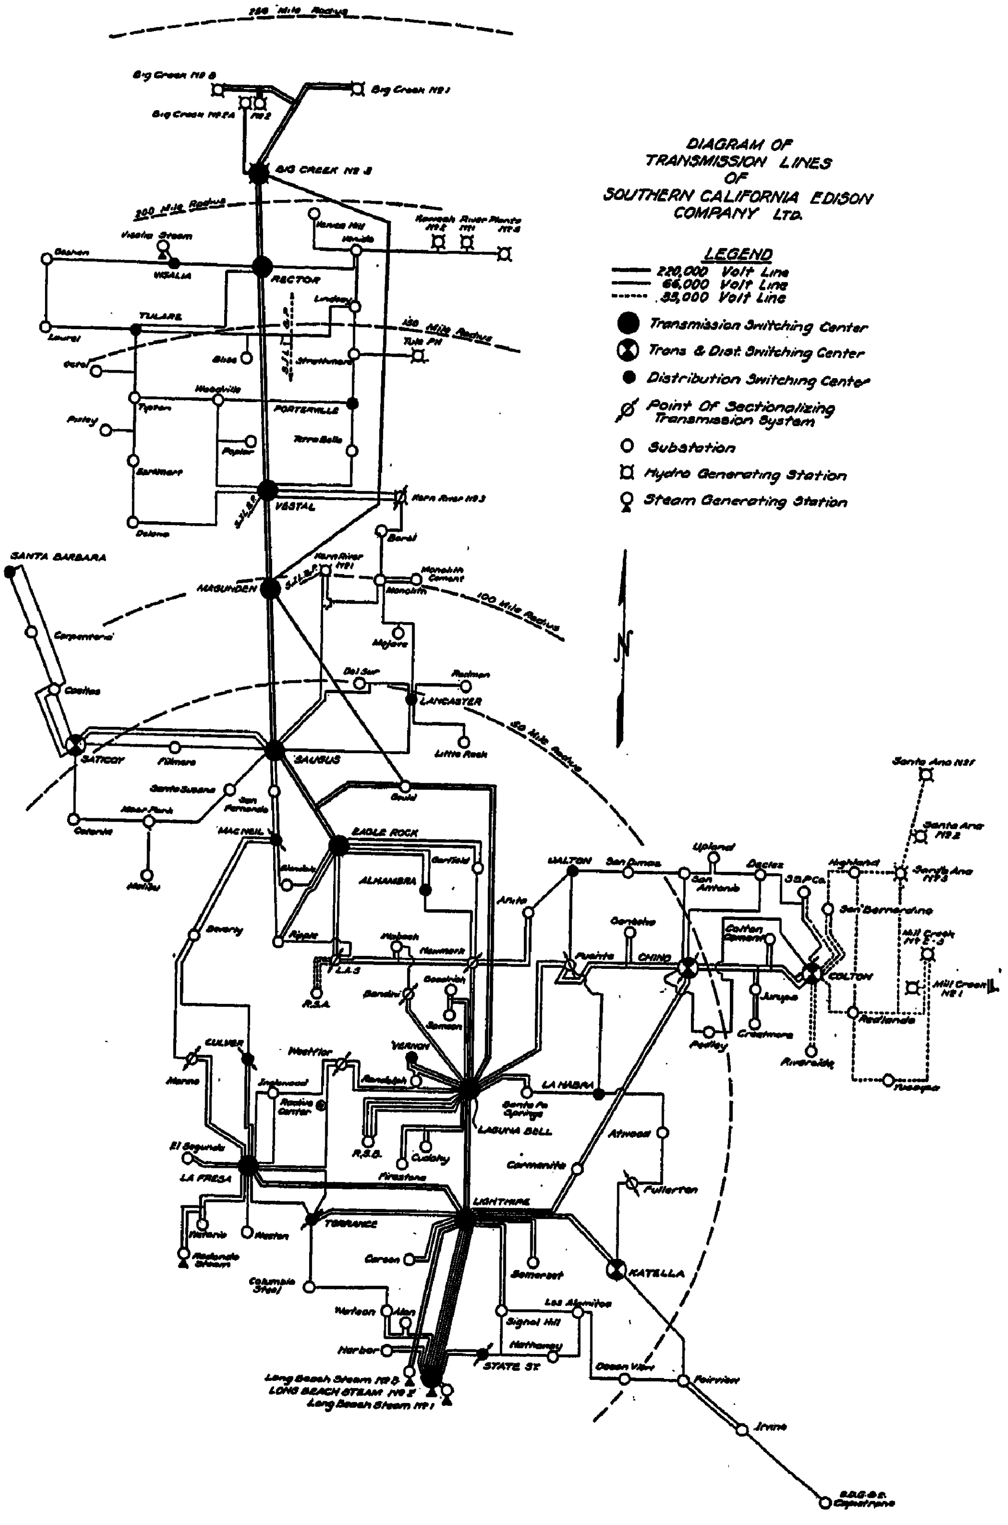
During the past few years the 66-kv. network of the Southern California Edison Company, Ltd., has been rearranged considerably particularly from the standpoint of routine operation and protection. Prior to some four years ago, the 220/66-kv. transmission receiving stations were interconnected quite closely on the 66-kv. side with the 66-kv. distribution stations looped into these connecting lines. The general practise was to have two or more incoming 66-kv. lines to each substation. Reliance was placed upon power directional relays to isolate faults, but because of the necessity of progressive timing for selective operation, the possibility of quickly isolating extremely heavy short circuits adjacent to the 220-kv. receiving stations became even more difficult. Accordingly in 1926 it was decided to begin changing the 66-kv. system from a loop to a radial system wherein each of the 66-kv. distribution stations would be supplied by two or more 66-kv. lines from one of the receiving stations. Furthermore, every effort was to be made to limit the phase-to-phase or phase-to-ground 66-kv. short-circuit current to approximately 1,000,000 kva. with an occasional exceptional upper limit of 1,500,000 kva.

With such a plan of operation it no longer was necessary to rely upon power-directional relays progressively timed; hence it was possible to take advantage of the characteristics of current-balanced relays wherein the currents in corresponding phases of two or more lines balanced against each other. This permitted a more prompt clearing of 66-kv. faults with consequent improvement in system operation. The decrease in the short-circuit current and particularly the increased speed of clearing short circuits due to the use of these relays has resulted in a marked decrease in a tendency towards system instability at the time of 66-kv. faults. As an adjunct to the line relays, current-balanced residual or ground relays when necessary have been installed and provision made to maintain protection by means of overcurrent or power-directional phase or residual relays for single-line protection.

16-Kv. and 11-Kv. System Protection

Heretofore the usual Edison method of providing for supply to 16-kv. or 11-kv. substations was by means of a separate feeder or a tap from a feeder radiating from a 66-kv. substation. During the past two years steps have been taken to provide two or more sources of supply to these lower-voltage substations, using either a scheme of loop operation between two 66-kv. substations or the preferred-and-emergency-supply method of operation. Recent analysis of the status of these lower-voltage substations supplied from the major 66-kv. stations shows that at present there are 35 distribution substations being operated on the loop system, of which 24 stations are operated on the 16-kv. system and eleven on the 11-kv. system.

A study of the cases of trouble experienced on lines supplying these stations shows that 38 cases of trouble were experienced during the first six months of 1930, and that 31 out of the 38 cases were cleared



Semi-geographic diagram of the transmission lines of the Southern California Edison Company, Ltd., showing the general plan of 66-kv. parallel-line supply to distributing stations adjacent to major receiving stations

correctly. In analyzing the seven cases which did not operate correctly it was found that two were caused by mechanical trouble in the oil circuit breakers, two by incorrect relay wiring, one by insufficient ground current, one by the d-c. trip circuit being de-energized, and one by unknown conditions. This record shows that there is room for improvement; however, results were so much more satisfactory than would have been experienced had the substations been supplied from a single radial line, as had been the practise in the past, that it is believed that loop operation of low-voltage distribution substations is successful and should prove a very efficient factor in minimizing service interruptions.

An analysis of experiences with the preferred-and-emergency scheme of operation shows that during the first six months of 1930 there were five cases in which the supply had to be changed over. In that period the only case of trouble experienced arose from a minor mechanical adjustment which caused one of the stations to fail to function properly.

Operating Experiences and Resulting Conclusions

For the past several years careful records of the performance of protective relays and automatic oil circuit breakers have been kept by the Edison company; Table III is a tabulated summary of 1929 experiences. It may be noted that the trend is towards fewer cases of trouble and consequently, generalizing, fewer automatic switch operations. There has been a decided decrease in unnecessary switch operations, which shows the result of wider application of protective relays with better knowledge of their characteristics and limitations. Intensive studies of the magnitude and distribution of phase-to-phase and phase-to-ground short-circuit currents have been of immense value in determining proper relay settings for various types and locations of faults.

TABLE III—OPERATION OF PROTECTIVE EQUIPMENT
220 Kv. to 11 Kv. Inclusive

	Year				
	1925	1926	1927	1928	1929
Cases of trouble	1493	2185	1799	1415	1303
Automatic switch operations	2368	3231	2831	2085	1923
Unnecessary switch operations	278	316	287	151	70
Failure of switches to operate	50	47	48	25	33

Decrease in "failure of switches to operate" has not been as marked, but these failures in general are the result of some form of trouble on the tripping side of the protective relays. A tripping coil may become defective, an auxiliary switch in the tripping circuit may not be making proper contact, mechanical faults may develop in the oil circuit breaker operating mechanism, or the control wiring may be defective.

A program of inspection, testing, and careful maintenance of the oil circuit breakers, protective relays, and tripping circuits is the only means of lessening these "failures to operate." Summing up in brief the results of operating experiences with the 9,300 protective relays now installed on the Southern California Edison system, the following conclusions seem warranted:

(1) In the interest of assuring a more reliable performance of the protective relays on the 220-kv. transmission system under conditions of testing and overhauling the protective equipment as well as during normal operating conditions, duplicate sets of relays are installed. This permits protection to be retained at all times.

(2) Use of carrier-current pilot protection on a 95-mi. section of 220-kv. transmission line has been satisfactory and has shown the value of this form of protection under conditions which would not permit the use of other forms of protective relays.

(3) Use of current-balanced relays and radial lines between the 220-kv. major receiving stations and the 66-kv. distribution stations has been an improvement over the previous practise of looping through the 66-kv. stations between adjacent 220-kv. stations. Elimination of the necessity of depending upon progressively-timed power-directional relays has speeded up the time required to clear faults.

(4) The practise of looping 16-kv. and 11-kv. distribution stations between adjacent 66-kv. stations in place of the previous practise of using single radial lines has resulted in a marked improvement in service.

(5) In rural districts the use of a remote alarm between unattended and attended stations to indicate when an oil circuit breaker trips out at the unattended stations has lessened the time of outage considerably. Private telephone lines or carrier-current equipment coupled to the transmission lines permits the installation of this remote alarm at a reasonable expenditure.

Allied Considerations

Successful application of protective relays on a transmission system is so closely linked with the static and transient stability of the system that whenever relays are involved consideration must be given to these characteristics. Stability is the limiting feature of long high-voltage transmission lines which determines the amount of power possible to handle commercially. It is obvious that the stability of a transmission system is determined by the longest section of line which may be isolated suddenly from the system to clear a fault. The static stability limit can be calculated readily to make it plain that if the power demand is such that the reduced transmission line capacity will not hold the generating and receiving ends of the line in synchronism, instability will result. Determination of the transient stability limit does not readily permit a definite solution since the factors to be considered cannot always be obtained with desirable accuracy. However, there is a number of outstanding features which can be considered and applied to a transmission system which will help greatly in maintaining stability under conditions of heavy short-circuit currents. Briefly stated these are:

1. Prompt clearing of faults is of prime importance in minimizing the loss of synchronism between the generating and receiving ends of a line.
2. A high short-circuit ratio (between 1.5 and 2) in generators and synchronous condensers aids materially in improving system stability.
3. Quick response or super-excitation for the fields of synchronous machines assists in maintaining transient stability.
4. The desirability of limiting ground currents so as to reduce the power demand on the transmission system at the time of faults is well established. This can be accomplished by installing current-limiting reactors in the transformer neutrals.
5. Momentarily decreasing the output of generators at the sending end of a long line at the time of faults reduces the likelihood of the two ends of the line dropping out of step.
6. A knowledge of the stability characteristics of the load supplied is helpful in making line stability calculations.
7. In studying relay problems or predicting inductive interference ground impedance along the line must be considered.

Resistance Welding Improves Motor Frames

The ever present demand for cost reduction calls for continual revision of manufacturing methods. Motor frames as now made from rolled plate instead of castings as formerly used represent one such revision. Manufacturing methods are outlined here; oscillographic records reveal something of the character of a resistance flash weld.

By Malcolm Thomson
Associate A. I. E. E.

General Electric Company
Lynn, Mass.

ELECTRIC WELDING in its various phases has been the means of reducing the manufacturing costs of many industrial products. Three methods of welding are in common use today; namely, the carbon arc, the metallic arc, and the resistance methods. Of these three the resistance method has proved to be especially adapted to the welding of electric motor frames, having been used for this purpose since 1928. In this way motor frames can be fabricated from structural steel at a marked saving in cost as compared to corresponding cast-steel frames. In addition, these welded frames possess the distinct advantage of greater uniformity in both dimensions and structure.

Steel of the proper width and length for the rings, and with necessary allowance in length made for welding and sizing operations, is ordered from the mills in carload lots. That which has been found most suitable for magnet frames is a basic open-hearth-process steel of low carbon content. The slabs of the various sizes required for different sizes of magnet frames are unloaded at one end of the department; these are passed to a 1,200-ton hydraulic press which crimps or curls the ends to avoid flats and waste of stock at portions which cannot be rolled.

A view showing the steel as purchased and also illustrating the various steps in fabrication is given in Fig. 1. A typical ring in bending rolls is shown in Fig. 2. Attention is called to the vertical plate which insures accurate alinement of the ends of the ring during the rolling process. Electric motor drive is provided for raising and lowering rolls, as well as for the rolls themselves. The end section is pivoted and controlled by an air cylinder as shown in the figure, thus providing for quick removal of the rings.

From the rolls the rings pass by conveyer of considerable storage capacity, to a specially designed resistance flash welder of the Thomson-Gibb type. In Fig. 3 this welder is shown in action. The rings are held in place with powerful clamps actuated by hydraulic cylinders against special aluminum bronze die blocks. The operator first separates the ends of the rings slightly; then starts slowly feeding the jaws of the machine together with a hand-valve control of the hydraulic push-up cylinder.

Current is turned on by a push-button actuating a small contactor which in turn controls a large contactor, the latter closing the connection of the primary of the transformer to the power lines. As the ends of the ring meet, first a feeble, then a violent flashing occurs. A predetermined amount of metal is flashed off, averaging slightly less than an inch total. The abutting faces are brought to the melting point of the steel by the flashing process whereas the areas immediately behind are brought to a welding heat mainly by conduction, but partly by resistance. At the end of the flashing period, the full pressure of the hydraulic ram, which is about 100,000 lb., is applied, suddenly forcing the molten faces together. The result is a perfect and homogeneous weld, all burnt or oxidized metal being forced out. This welder while rated at 12 sq. in. cross-section maximum, is sometimes used on sections up to 18 sq. in. The welder has a 750-kv-a. water-cooled transformer with an open-circuit voltage of 12 at the welding jaws.

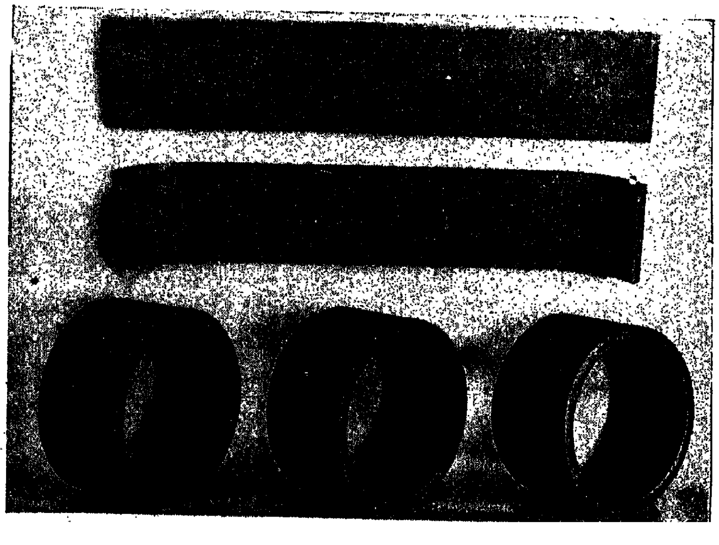

Fig. 1. Successive stages in fabrication of electric motor frame from structural steel slabs

---

From "Resistance Welding of Motor Frames," (No. 31-6) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

Due to the severe nature of the service, the demands on welding transformers require special features of design. The service is intermittent but large amounts of current are necessary, particularly at the final or upset period of the welding cycle. In order to facilitate repairs, accessibility is an important feature; hence the coils are usually assembled on a straight core section, a U-shaped section being then placed in position and fastened with bolts and straps to the straight section. On 60-cycle supply the core is worked at a flux density of from 60,000 to 80,000 lines per sq. in.

The secondary of this transformer consists of a single turn usually of cast copper with tubes for cooling water included in the casting. In larger transformers several cast-copper sections are often connected in parallel. The ends of the copper secondary are machined, one end being fastened solidly to the fixed platen. The other end is bolted to a flexible lead made up of many thin sections of copper strip, this lead being connected to the movable platen. The welding dies are located on top of the platens and are made of hard-rolled copper or special wear-resisting material, depending on the nature of the service for which they are intended. The work is very solidly clamped to these die blocks because of the push-up pressure required. The cast copper is worked at a current density of from 1,800 to 2,200 amperes per sq. in., the flexible leads at from 2,000 to 2,400 amperes and the joints at from 400 to 600 amperes per sq. in. The dies are worked at about 3,000 amperes per sq. in. current density. Wherever possible dies and platen as well as the transformer secondary are water-cooled internally and to avoid any unnecessary voltage drop the length of the secondary circuit is kept at a minimum.

Primary coils of the larger type transformers are usually built up of copper strip insulated between layers by a sleeve cloth or layer of asbestos paper. The coils are impregnated and baked; then wound with tape and finally painted.

Voltage regulation on the primary is obtained either by use of a separate auto-transformer or by bringing out taps to a regulating switch. Usually there are from five to ten points of voltage regulation, the lowest being about 50 per cent of the highest. Since on production work the breaking of the current may occur several times per minute, contactors used to switch on the power supply must be able to break full load of the welder without undue arcing or overheating.

Readings taken while welding a section of 18 sq. in. show that a primary current of about 900 amperes is required during the flashing period with a peak load of 2,250 amperes at the final or completion period of weld when the ring is forced together. The primary voltage at the time of these readings was 236, the transformer being supplied from a 60-cycle circuit. At high point

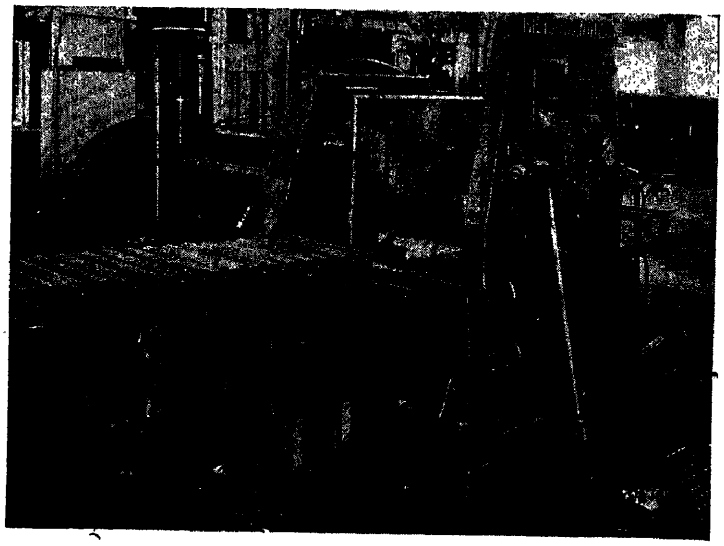

Fig. 2. Rolling machine for forming steel slabs into rings for motor frames

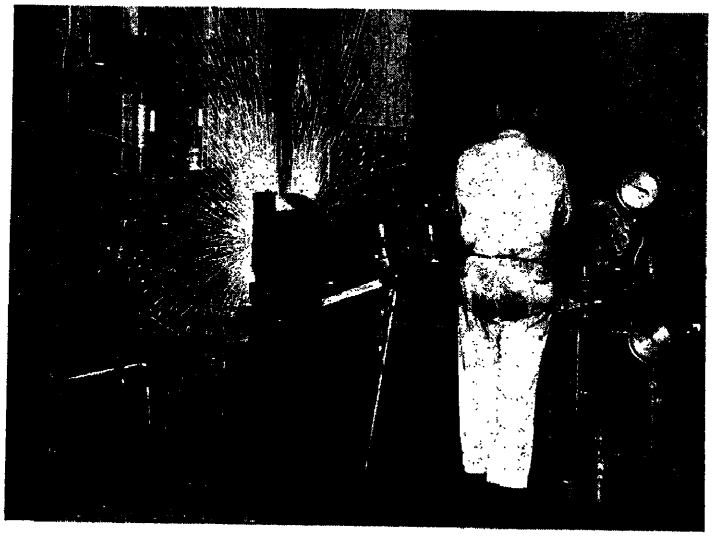

Fig. 3. A Thomson-Gibb resistance flash welder in operation. Magnetic field expels molten particles rather forcefully upward

Fig. 4. A hydraulic press for sizing welded frame rings

of weld, readings taken show a maximum of 461,250 volt-amperes and 252,000 watts power consumption, which gives a power factor of about 55 per cent. The average during flashing was 126,000 watts; power consumption with the secondary open, 1,400 watts.

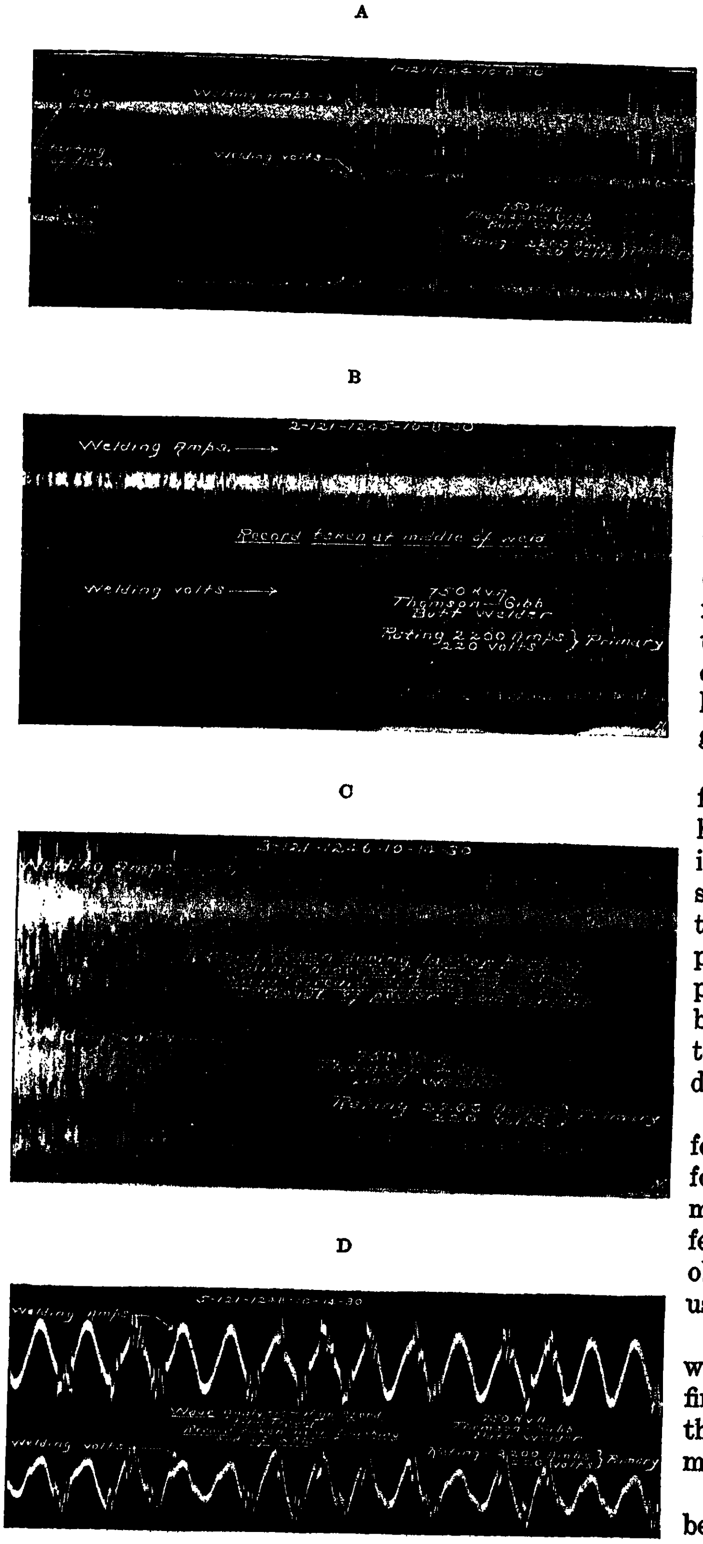

Fig. 5. Voltage and current relations at various stages in process of resistance weld. From top to bottom: beginning of flash period; middle of flash period; final stages; and wave analysis near close of flash period

Oscillograph records made on this welder are reproduced in Fig. 5. *"A"* shows conditions at start of flash, which consists first of a brief interval of short circuit, and then open circuit followed by beginning of contact of pieces. This represents a period of feeble flashing. As the flashing becomes more violent, conditions are as shown in *"B."* Toward the end of the flashing period, as shown in *"C"* when flashing appears continuous, the wave form still shows no continuous flow of current, but rather closely compact intervals of short circuit and open circuit. This picture also shows the upset or final push-up section of weld. A high-speed oscillogram made near the end of the flashing period is shown in *"D."* This illustration shows in some detail the intermittent nature of current during this period of the weld.

After the welding operation is completed, the ring is removed from the welder by an electric hoist. The upset resulting from the welding operation is removed by a vertical motor-driven broach which trims both the outside and inside of the ring while the metal is still red hot. The rings then pass by a conveyor similar to that previously mentioned, to an electric furnace. The electric furnace operation, while primarily used for heating rings for sizing, is advantageous also in that it gives the rings a strain anneal.

Rings are heated in this furnace to about 1400 deg. fahr. and then pass down a slide to an eight-cylinder hydraulic press located in the floor of the plant as shown in Fig. 6. (Part of the flooring has been removed to show the construction of the press.) It may be noted that in order to accommodate various sizes of rings this press is so built that each cylinder has a removable head portion. Rings are lowered horizontally into the press by means of an air-operated table and are then squeezed to within from 1/16 in. to 3/32 in. of correct size, depending on the size of the ring.

The frames are now complete with the exception of feet. The feet are made from steel bent into a "U" form in a hydraulic press, and are then cut apart by means of a gas torch. Each "U" makes one pair of feet and by inverting the "U's," right and left pairs are obtained. It is customary to cut all four feet at once using a double-torch machine for this purpose.

The sized rings pass by another conveyor to arc welding stations where the feet are tack-welded, then finish-welded into place. The completed frames are then sand-blasted, after which they are shipped to the motor building for machining and assembly.

By the use of electric welding of two kinds it has been possible to produce frames from 25 to 50 per cent cheaper than corresponding steel castings, with the added advantage of much greater uniformity in dimensions and structure. This, in turn, reflects a lowering of the machining costs and the production of better motors.

Low-Frequency Induction

The present status of joint development and research on low-frequency induction as it affects the closely associated circuits of the electric service and the communication utilities is outlined here.

INVESTIGATIONS being carried on by the Joint Subcommittee on Development and Research of the National Electric Light Association and the Bell System are in large measure concerned with induction at power-system fundamental frequency, its disturbing effects on communication systems, and remedial measures. This commonly-called low-frequency induction, has different characteristics and produces quite different effects from induction at noise frequencies as discussed in a companion paper by Messrs. Blackwell and Wills. Since very little has been published on low-frequency induction, it seems desirable to explain the problem in some detail in order to make clear what the joint subcommittee on development and research is doing on this subject.

Low-frequency inductive disturbances rarely occur under normal operation but are due usually to large unbalanced (residual) currents coincident with accidental faults in the power system. Although such abnormal conditions occur infrequently and usually last for only very short periods, the effects may be so serious that protection against this type of induction is an outstanding problem in the coordination of power and telephone systems.

Residual voltages and currents in effect are single-phase voltages and currents acting in a circuit consisting of the three line conductors in parallel as one side and the earth as the other side. Their large inductive effects are due to the great separation between the two sides of this earth return circuit, much of the return current being effectively so deep in the earth that its neutralizing action is small. The magnitude of these residuals is determined by (1) the power voltage and supply; (2) the impedances of lines, apparatus, earth, and fault; (3) configuration of conductors; and (4) characteristics of ground wires. Their frequency of occurrence depends upon the design and quality of construction employed, and upon the nature of external influences. Their duration is controlled by the effectiveness and speed of the relays and circuit breakers.

The magnitude of the voltages which these residuals induce into the communication circuits is principally determined by the location of the fault and magnitude of the residual current, the length of the exposure, the separation between power and communication lines, the location of ground connections on the two systems, and geological conditions affecting earth conductivity.

TYPICAL EXAMPLE

As illustrative of the effect of each of these factors, consider an exposure between a three-phase 26-kv. power line and a telephone line: The configuration of the conductors on the power line is an equilateral triangle, 30-in. spacing, conductors 250,000-cir. mil copper, height above the ground 40 ft., fault or residual current 1,000 amperes with the fault-to-ground at the end of the exposure. The exposure is five miles long with a uniform separation of 40 ft. between the power and telephone lines; height of the telephone line 25 ft. The assumed conductivity of the earth is 10^{-12} abmhos per cm. cube. Under these conditions, the induced voltage in the telephone line will be 1,870 volts. The effect of a change in the different factors on the induced voltage on the telephone line is as follows:

	CONDITION	INDUCED VOLTS
1.	Length of exposure doubled (10 miles)	3,740
2.	Residual current reduced to 500 amperes	935
3.	Residual current reduced to 200 amperes	374
4.	Separation increased to 60-ft.	1,700
5.	Separation increased to 3,000-ft.	34.5
6.	Earth conductivity 10^{-13} abmhos per cm.^{3} (40-ft. separation)	2,530
7.	Earth conductivity 10^{-14} abmhos per cm.^{3} (40-ft. separation)	3,200
8.	Earth conductivity 10^{-13} abmhos per cm.^{3} (3,000-ft. separation)	280
9.	Earth conductivity 10^{-14} abmhos per cm.^{3} (3,000-ft. separation)	792
10.	2/0-copper shield wire, grounded at both ends, installed on power line (zero ground resistance)	925
11.	2/0-copper shield wire grounded at both ends, installed on power line (5 ohms ground resistance)	1,370

Low-frequency and transient voltages induced on communication circuits may produce a variety of effects depending upon their magnitude and duration. These effects may include interruption of service, false signals, distortion of telegraph signals, damage to central office or other plant, acoustic shock, and electric shock.

Of the protective measures which reduce inductive influence, some are concerned with fundamental questions of power-system design; others with changes in circuit or grounding conditions, lines, equipment or operating methods. It is evident that protective measures to reduce the inductive influence of power

---

From "Status of Joint Development and Research on Low-Frequency Induction," (No. 31-23) presented at the A. I. E. E. winter convention as Part III of a symposium on coordination of power and telephone plant.

systems should be directed to limiting the magnitudes of the unbalance currents and voltages, particularly under abnormal conditions, and to reducing the duration and frequency of occurrence of abnormal conditions. Some of these protective features are preferably incorporated in the system when constructed as a result of cooperative advance planning, while others may be added later to care for effects due to subsequent developments in either the power or telephone system.

POWER SYSTEM PROTECTIVE MEASURES

Protective measures in the power system, which are available or under investigation for mitigating or eliminating these effects, are briefly described below.

Reduction in the frequency of occurrence of faults involves primarily the design and construction of the power line; that is, adequate insulation, clearance and spacings, and so arranging the component parts of the structure that the line will in effect be fault resistive. The principal elements which enter this problem are (a) design and spacing of conductors including ground wire so as to prevent arcing between them under expected conditions of sleet and wind loading, (b) proper mechanical strength of structures to withstand expected loading and (c) design and location of guys so as to provide adequate mechanical strength and at the same time make the minimum reduction in clearances and insulation.

The proper location of lines is a material factor in limiting the number of outages resulting from external sources, such as lightning, broken trees, blasting, and automobiles. The amount of insulation to be employed on lines should be governed by topographical and climatic conditions, and special attention should be given to areas where salt, fog, smoke, or chemical fumes are prevalent.

Resistors or reactors in the neutral ground connection of a power system provide a means of directly limiting the magnitude of the residual currents except in cases of double faults. In cases where without reacting unfavorably upon power system operation, the residual currents can be so far reduced as not to set up induced voltages of high values in the communication system this method alone may afford a satisfactory solution. In such cases it has the further advantage of reducing the stresses to the power system due to the fault current. Where it is impracticable to clear up a situation by residual-current limitation alone, this method may be effectively used in combination with other protective measures. Included in this work is a study of the relative advantages of inductance as compared with resistance for accomplishing such current limitation.

In non-grounded power systems a single fault on a phase conductor results in the charging current of the system flowing to earth through the fault. The other phases, rising to full-line voltage above the grounded phase, create a system unbalance which may manifest itself by induction in paralleling communication lines. In such cases the problem is one of electric induction except for the magnetic induction set up by the charging current.

Ground wires on a power line, while tending to increase the total residual current, serve the purpose of shielding by reducing the strength of the external electric and magnetic fields set up by the residual voltages and currents. The net effect of ground wires from the low-frequency standpoint is to reduce the voltages induced in paralleling communication circuits under abnormal power-circuit conditions. Such ground wires, if used on wood-pole lines, have a disadvantage in that they impair to some extent the insulating property of the poles.

High-speed breakers and relays are expensive and it is difficult to justify them solely as a remedial measure for induction, particularly as the speeds of operation now available for relays and breakers on power systems have not reached values which make them a complete solution of coordination problems. However, with the increasing size and interconnection of power systems, high-speed relays and circuit breakers are playing an increasingly important part in promoting power system stability.

The subcommittee is following the developments in high-speed breakers and relays with much interest; if such devices should come into general use for all classes of service it is expected that they will materially improve the whole inductive situation.

TELEPHONE SYSTEM PROTECTIVE MEASURES

In general, measures applicable to the communication system to prevent or reduce the effects of induced voltages take the form of arrangements or devices for removing or counteracting the voltages to ground or the currents in the telephone circuits which might be produced by induced voltages.

Protective measures in the communication system which are available or under investigation are briefly described as follows:

Bell System standard protective devices are intended to offer a measure of protection against lightning discharges and against the voltages and currents resulting from accidental contact with foreign wires, or from low-frequency induction.

In order to protect telephone linemen or others working on open-wire lines against electric shock from induced voltages, it is necessary that the voltages between line wires and between each line wire and ground be kept low. The use of protectors at central offices does not so protect the linemen as the impedance drop on the line wires permits high voltages between wires and ground at other points, such as the terminals of the exposed section.

In view of the inadequacy of existing forms of protectors for such use, the subcommittee is experimenting with a relay protector. This device includes Bell standard protectors in combination with a relay which operates to short-circuit them upon the occurrence of a discharge, thus relieving the protectors of the duty of carrying the large discharge current and greatly reducing their tendency to become permanently grounded.

The effective application of such protectors requires grounds of the order of one to two ohms, and an important feature of the investigation is to devise methods of constructing and maintaining such grounds at remote points along the line.

Since acoustic shock due to induced voltages involves dissymmetrical discharges across the two sides of the protector, efforts have been made to devise a protector which would break down and discharge symmetrically; *i. e.*, provide two reliable, low-impedance paths for heavy discharges which would at all times have very closely the same arcing impedance. Thus far the subcommittee has not been successful in developing a practical protector of this kind. In cases where toll or trunk lines are exposed, an acoustic-shock-reducing device which could be placed at the ends of the lines would have the advantage of protecting subscribers as well as operators. Development work to obviate certain difficulties in using such a device is under way and effort is being made to develop a telephone receiver which will saturate between the values of current required for effective speech transmission and values of current which produce acoustic shock. This requires a sharp bend in the saturation curve of the iron employed in the receiver magnetic circuit. Until the development of permalloy, this feature was not approachable, but experimental permalloy receivers have now been developed, and while it has not yet been possible to achieve the end sought without serious sacrifice in transmission, work along this line is continuing.

Drainage is a method for controlling the parts of the circuit in which the induced voltages appear, and causing these voltages to be consumed in parts where they are least harmful. This is accomplished by connecting the telephone conductors to ground (preferably through balanced impedance coils) at certain points throughout the exposure. Under present conditions, the application of drainage is limited to special situations where interference with circuit testing and maintenance is of relatively minor importance, and where superposed d-c. telegraph and carrier telephone are not used.

The neutralizing transformer is a device for introducing into an exposed communication wire a voltage in opposition to the voltage induced by the disturbing circuit, thereby to a certain extent neutralizing the latter. On account of introducing crosstalk, and adversely affecting telephone transmission and carrier, application of neutralizing transformers has been confined chiefly to telegraph circuits. They are being studied by the subcommittee to see whether or not the objections mentioned above can be overcome; also to determine their field of possible application.

Shielding on a telephone line may be effected by special grounded conductors, by working conductors or by cable sheaths. Miscellaneous structures such as pipe lines or rails in the immediate vicinity of an exposure also introduce more or less shielding. If the lead sheath of the cable is surrounded by magnetic material, as by armoring or placing cable in iron pipe, the shielding may be largely increased.

As bearing on the prevention of electric shock from induced voltages on telephone lines, shielding has a disadvantage, in that depending somewhat on the method of construction, it may add to the chance of a lineman making contact with grounded metal.

COORDINATED PROTECTION

Joint measures which may greatly obviate the ill effects of low-frequency induction are: Coordinated advance planning in order to effect the most advantageous location of new lines, and coordination of grounding practises to obtain separation of power and communication ground connections.

The ideal protective measure would be one which furnished adequate protection and had no unfavorable reaction from an economic or service standpoint on the system to which it is applied; however, the work thus far has not disclosed any measure which fully meets this ideal. The relative advantages of different protective measures differ in specific cases. The best solution for any case is the one which correctly balances technical results against over-all cost. Adequate separation of circuits is the most effective measure, but where this is not practicable, fault current limitation in the power system, and cable (particularly if shielded) for the communication circuits, afford the most generally effective protection (where applicable). In many situations, no single protective measure is adequate and two or more in combination are required.

As telephone circuits which are exposed to induced voltages may also be exposed to possible contact with power circuits and to lightning, any comprehensive scheme of protection must include consideration of the high currents resulting from contact and the high voltage due to lightning. The voltages produced by contact or lightning are somewhat similar in their effects to the voltages produced by induction, but differ in many important respects: Lightning requires protectors of a very high speed of operation, whereas contacts with power circuits necessitate protectors of high-current carrying capacity.

The program of work on low-frequency induction, undertaken by the Joint Subcommittee on Development and Research through its project committees, is laid out to develop the essential facts bearing on the problem of telephone protection in a broad sense, including causes, effects, and remedial measures. The program covers both the technical and the economic aspects of the problem.

Extensive field trials of the more promising protective measures are under way in order to determine their practicability under operating conditions. As the work progresses it is expected to issue from time to time reports covering the applicability, efficacy, limitations and conditions of use of various measures. This should result in a better understanding of the problem and more effective and economical solutions of specific situations as they arise.

A bibliography listing 32 of the more important writings on this subject which have come to the attention of the authors is given as a part of the winter convention paper of which the foregoing is an abstract.

Noise-Frequency Induction

The present status of joint development and research on noise-frequency induction as it affects the closely associated circuits of the electric service and the communication utilities is outlined here.

By H. L. Wills *and* *O. B. Blackwell*

Associate A. I. E. E.
Georgia Power Company
Atlanta

Fellow A. I. E. E.
American Tel. & Tel. Co.
New York

OFTEN IT HAS been remarked that few problems are difficult to solve if all the facts bearing on them can be determined. The work of finding out the technical facts bearing on the problems of the physical relations of power and telephone circuits was intrusted to the Joint Subcommittee on Development and Research of the National Electric Light Association and the Bell System. This paper has to do with this fact-finding work so far as it concerns noise-frequency induction.

This joint subcommittee has subdivided its work among eleven project committees and has assigned to each the carrying on of specific research problems. It is not possible in the scope of this paper to discuss these various project committees and their work in detail; for the most part, results of the work of these project committees which have been published, or will be published in the future, must speak for them. The work on inductive coordination may be classified into three groups of factors:

1. Influence factors which concern the characteristics of the power circuits.
2. Susceptiveness factors, which concern the characteristics of the communication circuits.
3. Coupling factors, which concern the interrelation of power and communication circuits.

Before discussing these groups of factors it will be of interest to review the subject briefly from another point of view; namely, according to the methods which may be employed for the control of inductive interference. These methods are as follows:

Where two systems react unfavorably on each other, the first thought naturally is to keep them apart physically. In cases where the operating power and communication companies maintain close contact in their planning work, this may be a most effective method of handling coordination of important power-transmission lines and toll-telephone leads. With local distributing power and telephone systems, however, the need for serving the same customers requires that the systems be close neighbors. In connection with the matter of physical separation it should be noted that while a separation between lines of a few hundred feet practically eliminates the noise frequency problem, the low-frequency problem may exist with much greater separations. Where physical separation cannot be brought about, the methods of coordination employed must be along the lines of electrical separation. There are here three possibilities: Frequency separation, electrical balance, and shielding.

The idea of electrical separation by use of different frequencies is familiar to nearly every one today because of the development of radio broadcasting. It is happily true that the frequencies used for power transmission are comparatively low, and the frequencies necessary for good speech transmission are ordinarily well above this range. The figure shows a diagram of the various uses of the frequency spectrum for electrical transmission, and the manner in which power and telephone services are coordinated by frequency separation.

An important part of this matter of frequency separation is evidently the question of wave shape in the power systems and the relative amounts of power employed in the two systems. While the amounts of power at harmonics of the fundamental frequency in power circuits are negligible in comparison with the total power transmitted, they are large compared with the

---

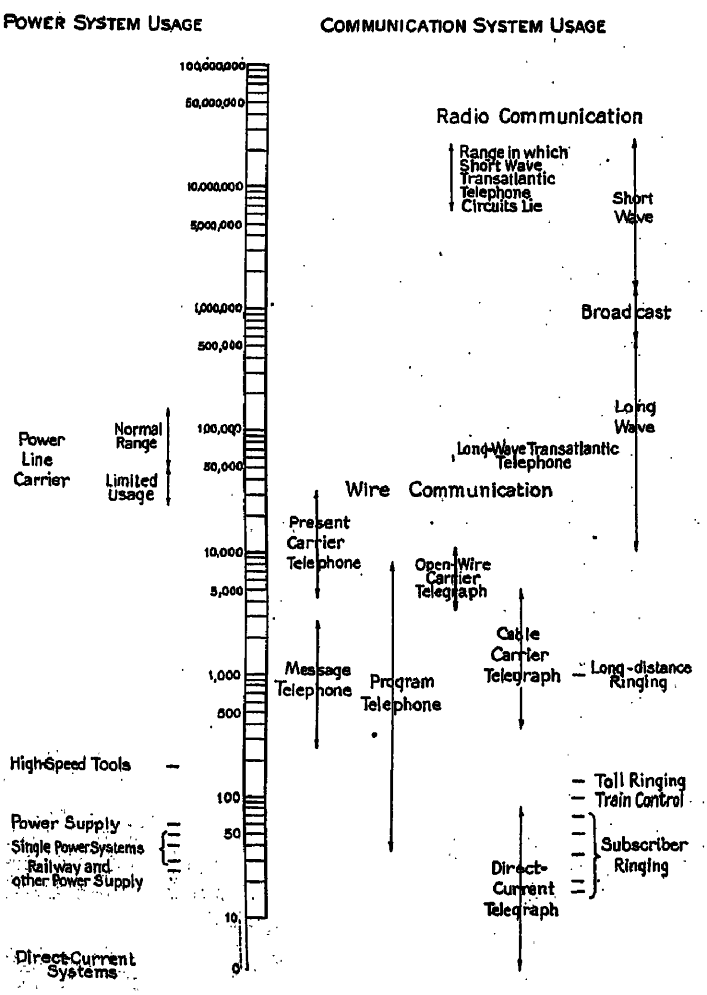
From "Status of Joint Development and Research on Noise-Frequency Induction," (No. 31-22) presented at the A. I. E. E. winter convention Part II of a symposium on coordination of power and telephone plant.

power employed in the telephone circuits, and fall directly within the frequency range used for telephone transmission. On the other hand, while the powers involved in telephone transmission are small compared with those on power lines, they are, in turn, large as compared with the acoustic power received from the talker or delivered to the listener.

Electrical balance is another fundamental means of bringing about electrical separation. A perfectly balanced power circuit could not influence an adjacent communication circuit; nor could a perfectly balanced communication circuit be interfered with by a power circuit. Perfect balance, however, is a virtue which is difficult to obtain, and the problems of balance in electrical circuits present some of the most interesting and difficult technical questions being considered.

Shielding is a third possible method of electrically separating two systems. The different wires of a telephone line have an important shielding effect on each other. The most important practical phase of shielding is the use of lead sheaths on telephone cables which have a most important effect in practically eliminating electric induction in the cables. The method is limited, however, by the difficulty of bringing about a comparable degree of magnetic shielding.

FREQUENCIES USED FOR ELECTRICAL TRANSMISSION



Returning to the method of analyzing inductive coordination into influence, susceptiveness, and coupling factors, the important influence factors of power circuits are wave shape and unbalance on the operating voltages and currents. Wave shape is determined by the characteristics of the apparatus associated with the system; and balance is determined by the degree of symmetry of the generated voltages and of the apparatus load and line impedances. In order to obtain a broad picture of the wave-shape conditions that exist in the field of operating power systems equipped with various types of apparatus, an extensive survey was made including measurements on 34 operating power systems in the eastern half of the country. The program was arranged to obtain information as to the average and range of magnitudes of harmonics present in various types of transmission and distribution systems under normal operating conditions; to observe the relation between the wave shape of generating machinery under open-circuit conditions and under load; to study effects of various transformer connections on wave shape, and to observe the effects of various types and magnitudes of load. The data accumulated are being summarized in technical reports which will be published upon their completion.

The important sources of unbalance in power circuits are (1) triple-harmonic residual voltages and currents arising with rotating machinery or transformers connected in star with neutral grounded; (2) differences in the loads connected between the phase wires and neutral of three-phase four-wire distribution systems; and (3) differences in conductor capacitances-to-ground due to single-phase branches on three-phase systems.

Experience has indicated that the outstanding factor is the existence of the triple-harmonic residual voltages and currents. A large measure of control may be exercised on the magnitudes of the triple harmonics by the use of certain transformer connections and by avoiding the operation of transformers at high flux densities.

A technical report has been published dealing with noise-frequency induction which arises when star-connected generators operating with grounded neutrals are connected directly or through star-star transformer banks to transmission or distribution systems. Information is given on methods of reducing the influence under such conditions.

A laboratory study of transformer harmonics and transformer connections is under way; this is to be supplemented by tests on large transformers in the manufacturers' shops and in the field.

The important susceptiveness factors of telephone circuits are unbalance, sensitivity of the receiving apparatus, and operating power level of telephone circuits.

Unbalances in toll circuits are the result of commercial variation from the balanced condition, the circuits being designed to be symmetrical. These unbalances include resistances in joints, transposition irregularities, and differences in the impedances of shunt or series apparatus.

Because of the shielding effect of the telephone cable sheath, the high degree of balance of the terminal apparatus and the more general use of private rights-of-way, cases of noise-frequency induction into toll-cable circuits are comparatively infrequent.

Certain unbalances exist in exchange circuits due to the arrangements used for selective ringing, for coin box service, and for supervisory signaling. These unbalances have been investigated in detail and the results published in a technical report. Party-line unbalance due to the ringer ground is usually the controlling unbalance, so that coordination difficulties between telephone exchange systems and power distribution systems usually involve the party-line circuits before individual line circuits are affected.

The coupling between power and telephone circuits for a given degree of proximity depends upon the balance of the two classes of circuits to each other and ground. Advance has been made in methods for predetermining the coupling in new cases of exposure and for reducing the coupling in given situations of proximity. Extensive studies have been made of coupling of power-distribution circuits and telephone-exchange cable circuits using the same pole lines; the results have been published in technical reports. Much work has been done also on the coupling of open-wire telephone circuits both with power-distribution and power-transmission circuits; the results will be published as soon as they have been prepared in suitable form.

Coordinated transpositions of open-wire power and telephone circuits are a powerful tool for controlling this coupling. Available information is inadequate, however, as to the effectiveness of transposition in situations where important line irregularities occur which it is not possible to take into account in the transposition design. The subcommittee is investigating this problem.

Many of the existing noise-frequency induction problems have arisen because of the development of the art of the two industries without such close cooperation between them as now exists. From the work of this joint subcommittee it is becoming evident that while it is not practicable to design machinery and apparatus for power systems to be entirely free of harmonics, or to ideally balance either power or telephone circuits, it is possible to control these factors within limits which, in conjunction with the control of coupling obtainable by cooperative planning of routes and coordination of transpositions, permit satisfactory operation of both services without unduly burdening either.

A bibliography listing seventeen of the more important writings on this subject which have come to the attention of the authors is given as part of the winter convention of which the foregoing is an abstract.

Interference in Ocean Cable Telegraphy

The character of interference which may be present near the ends of submarine telegraph cables depends upon many local factors and can be determined only by actual field measurements. Relations between this interference and cable operation are discussed.

By J. W. Milnor

Fellow A. I. E. E.

Western Union Telegraph Co.
New York

PERFORMANCE of many submarine telegraph cables is affected by extraneous electrical interference. Often the message capacity is definitely limited by this factor. Consequently, it is desirable that the relations between interference and the performance of cables be studied and methods for measuring interference be developed and standardized.

The most common interference is of natural origin—from the same sources which cause the atmospheric disturbances or static which affect radio systems. Sometimes there is also interference caused by other cables or by electric railway or power systems. The amount of interference due to natural causes varies widely in different cables, being affected by the depth of the cable, the design of the core and the sheathing, the nature of the sea bottom, and other conditions. In general, the amount can be predicted only from measurements made in the vicinity.

Influence of interference upon the operation of cables is first discussed under the assumption that the interference is sinusoidal; this is then extended to include the actual interference which is quite irregular in form. Since the computations with non-sinusoidal interference are too tedious for general field use, an experimental method of measurement is given which may be used directly in determinations of the effects upon cable operation.

Interference and Cable Performance

If alternating current is transmitted into a cable and sinusoidal interference of approximately the same frequency is present at the opposite end, the relative

From "Submarine Cable Telegraphy: Influence of Interference," (No. 31-8) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1930.

deflections of the receiving instrument due to these two sources may be computed readily from the known characteristics of the cable. The deflections due to sinusoidal interference of other frequencies and to various combinations of telegraph characters received through the cable also may be computed; but for this purpose it is necessary to know the manner in which the receiving equipment responds to sine-wave voltages of various frequencies. Such a frequency characteristic may be computed from theory or determined experimentally. For satisfactory operation it appears necessary that the deflection due to telegraphic characters should be at least five times the deflection caused by interference. Ordinarily the interference in a cable is not sinusoidal. An example of its irregular form is given in Fig. 1.

Knowing the frequency characteristic of the equipment, it is practicable to determine its response to various simple forms of transient induced voltage such as might be caused by interference. The computation is straightforward and involves a single, definite integration ("Submarine Cable Telegraphy," A. I. E E. TRANS., 1922, p. 200); a number of examples have been worked out. It is also possible to compute the effect on signal reception of actual interference such as shown in Fig. 1; however, in that case the computations are too tedious for use in general studies of interference. Such computations are made unnecessary by the experimental method of investigation about to be described.

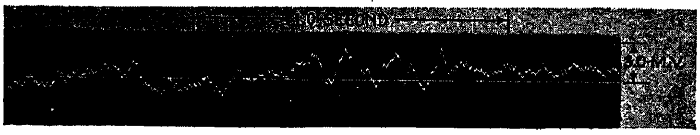

Fig. 1. Record of cable interference obtained using distortionless amplifier

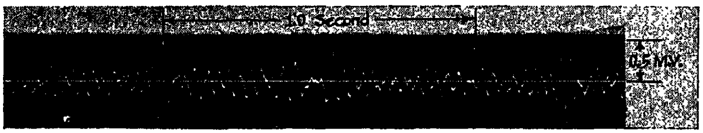

Fig. 2. Record of cable interference with amplifier tuned to 30 cycles per second; decrement = 0.8

FIELD MEASUREMENTS

Obviously the most accurate method for determining the practical effect of interference would be to obtain records using receiving equipment which is adjusted to give properly shaped signals on the given cable. This method is not always convenient and has certain other objections.

An examination of the frequency characteristic of efficient receiving equipment indicates that it is somewhat similar in general form to that of a simple electrically-tuned circuit, and the method therefore suggests itself of making use of such tuning while the field records are being obtained. Since the quantity to be measured is highly erratic in amount such a method has been found to be sufficiently accurate for the purpose. The frequency of the tuned circuit must correspond to that frequency at which the cable equipment is most sensitive, and the broadness of tuning should approximate that of the equipment.

A convenient arrangement of apparatus for the purpose is an oscillograph connected to the output of a vacuum-tube amplifier, the latter having a symmetrically-tuned circuit between two of the stages and being otherwise distortionless. The tuning may be provided by means of a low-loss inductor and condenser and resistor in parallel, this combination constituting the external-plate load of the preceding tube. The resistor controls the broadness of tuning, the broadness being conveniently specified by stating its logarithmic decrement. The highest peak on the oscillogram is recorded as the amount of interference under the given conditions.

A sample record obtained with such equipment is shown in Fig. 2; an example of the manner in which the peak interference varies with the tuning frequency is given in Fig. 3. The measured interference also varies with the decrement and with the length of the record. The resulting effects on cable behavior may be determined with the aid of the above discussion on the influence of sinusoidal interference.

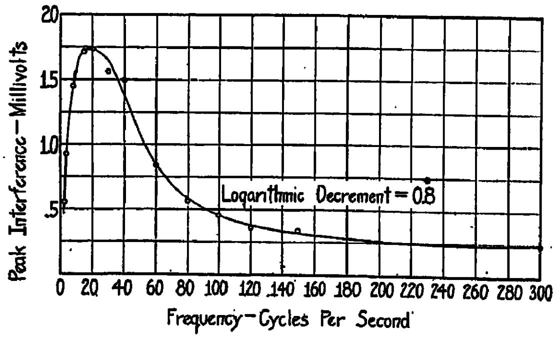

Fig. 3. Variation of peak interference with frequency of tuned circuit

IMPULSE RESPONSE CURVES

By means of a simple experiment it is possible to determine directly what may be termed an impulse characteristic of the receiving equipment associated with a cable. This characteristic as here used is defined as the transient response of the receiving instrument, when an instantaneous or pure impulse of voltage is impressed in series (across a small resistor) in between the cable and its receiving equipment. It is interesting to note that when the other is known either the frequency characteristic or the impulse characteristic may be computed by means of an integration. In order to determine the impulse characteristic experimentally, a charged condenser of proper size may be discharged across the resistor. An examination of such a characteristic yields valuable information as to the approximate frequency at which the equipment is tuned, and also gives an indication as to the sharpness of tuning and the sensitiveness.

Transforming Reactor Improves D-C. Arc Welding

Transients normally prone to occur in a welding generator are eliminated by compensating action of a simple device external to the generator; desirable external reactance also is provided for a welding circuit.

By S. R. Bergman
Associate A. I. E. E.
General Electric Company
West Lynn, Mass.

ARC WELDING, particularly when applied to ferrous metals has developed during the last decade into an art of great importance in industry. As this art progressed, the requirements for a proper power supply has been studied with the view of obtaining uniform and great strength of welds as well as ease in welding. To meet this demand, a motor-generator set has been developed and in addition, an auxiliary device of inductive character to aid the generator in producing ideal welding conditions.

Requirements for the generator may be stated briefly as follows:

1. The open-circuit voltage was chosen to range from 70 to 90 volts because experiments had shown that it is desirable to have this voltage above 70. With less voltage available, the arc has a tendency to break as it is elongated by unsteady welding or by the blowing from influences of external magnetic fields. This voltage is required also to break through scale on the iron. Tests have shown also that there is no advantage derived from a voltage higher than 80, although a margin of 10 volts above this to compensate for the voltage drop in long leads is advantageous.

2. The arc voltage runs from 14 to 25 depending upon the strength of the welding current. Thus it is required that the voltage of the generator should drop inherently from an open-circuit voltage of 70 or 80 to an arc voltage of 14 to 25. Regulation of the generator, as shown in Fig. 1, gives approximately a straight-line relation between voltage and current.

As illustrated in Fig. 2, the generator principle involved is that of a dual magnetic circuit. The armature is wound for two poles and the field contains four poles; in general, the armature should be wound for half the number of poles contained in the field. In d-c. machines of standard design adjacent poles have opposite polarity, but in this machine the poles are paired in groups of the same polarity (a group of two north poles followed by a group of two south poles).

To establish a working theory, assume that the flux distribution is as in Fig. 2. There exist two fluxes ϕ_m and ϕ_c displaced 90 electrical deg. from each other. The flux ϕ_m will be designated the main flux, and the flux ϕ_c, the cross-flux.

Load current of the armature is taken from the two brushes, *A* and *B*, placed at neutral points between poles of opposite polarity. In addition there is an exciting brush, *E*. This machine is self-excited, the excitation being taken from brushes *A* and *E* in Fig. 2. The main magnetic circuit is so designed that magnetic saturation exists, whereas the cross-magnetic circuit is designed without saturation. As soon as the armature is loaded there is set up an armature reaction *R*, which may be resolved into two components *R M* in the direction of the main flux and *R C* in opposition to the cross-flux. Since the main magnetic circuit is saturated, component *R M* cannot force any more flux through this circuit and the main flux remains practically constant. Component *R C*, however, blows out the cross-flux which thus decreases as the load increases. Machine voltage *A B* is the algebraic sum of *A E* and *E B*. Voltage *A E* is induced by the main flux and remains practically constant since the main flux and the speed are constant. Voltage *E B*, however, decreases with the load since the cross-flux decreases as

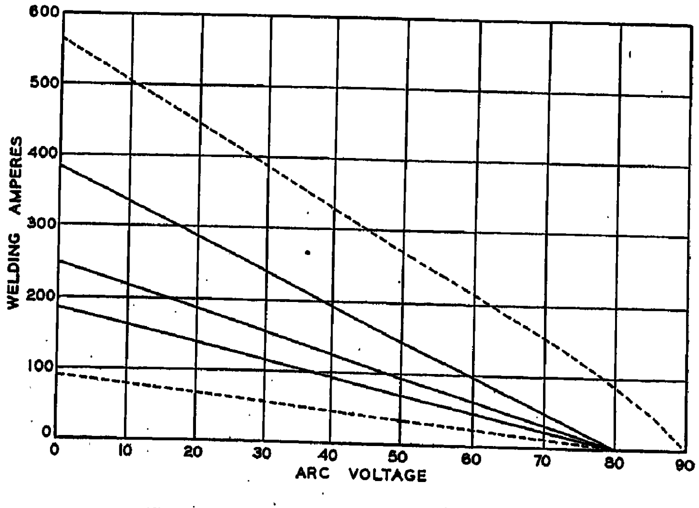

Fig. 1. Generator characteristics

From "A New System for D-C. Arc Welding," (No. 31-19) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

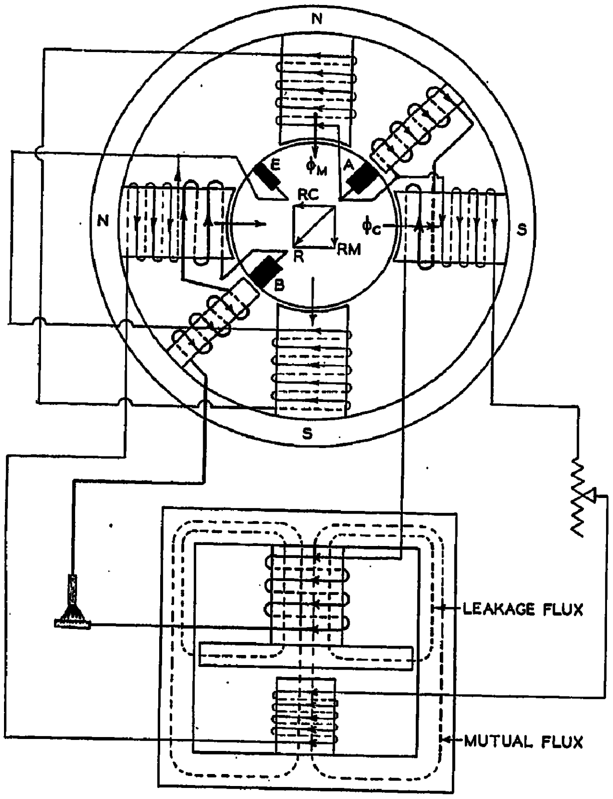

Fig. 2. Schematic diagram showing principles of generator and method of connecting transforming reactor

described. As a matter of fact, the cross-flux passes through zero and is finally reversed.

If it is desired to weld with smaller currents, a series winding is placed on the cross-poles supporting the armature reaction. It being desirable to obtain different welding currents, the series winding is provided with taps; and to secure close adjustment of the welding current a field rheostat is inserted in the cross-circuit. To obtain good commutation, commutating poles are added.

This design results in a set of welding currents as shown in Fig. 1 which particular curves apply to a machine rated at 300 amperes and capable of delivering a minimum of 75 amperes, and a maximum of 450 amperes.

In actual welding the current is never constant because the circuit frequently is short-circuited by small globules of metal and because the electrode is not fed at exactly the proper rate, particularly in hand welding. Under such conditions, transient currents and potentials appear in the generator and the regulation deviates from the curves shown in Fig. 1, which correspond to static conditions. In striking the arc, the current overshoots its steady value, and in breaking the arc a certain time interval is required for the voltage to return to its normal open-circuit value. It is desirable that the short-circuited current should not be excessive, and it is also desirable to have the voltage build up rapidly.

To cope with these transient conditions, a special inductive device which may be called a transforming reactor was developed. (Fig. 2) The primary winding of this device is connected in series with the arc, and its secondary winding in series with the shunt field of the cross-magnetic circuit. These two windings are connected in such a way that the direct current flowing through them will magnetize in the same direction.

The function of the transforming reactor is to provide external to the generator a magnetic coupling between the arc circuit and the field circuit, which coupling will be opposite in effect to that between the two circuits within the generator. Suppose that the arc is suddenly broken; then the ampere-turns of the arc circuit (both in the generator and in the transforming reactor) suddenly disappear and since the secondary winding attempts to maintain the mutual flux, the secondary current has a tendency to increase and counteract the tendency of the generator magnetic circuit to make it decrease. Thus the transforming reactor tends to keep the cross-shunt field current constant regardless of changes in the arc-current. The result of this is to make the voltage build up more rapidly to its normal value when the arc is broken, and to limit the peak value of current when a short-circuit is made.

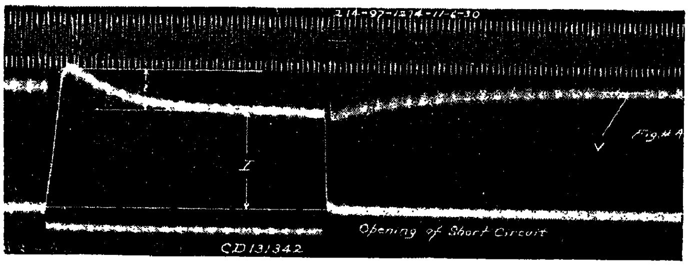

Fig. 3. Oscillographic record of action of combination of Fig. 2 under conditions of suddenly-applied and suddenly-relieved short circuit

To illustrate the principle of this generator in conjunction with the transforming reactor an oscillogram is shown in Fig. 3, showing what happens when the arc is short-circuited and the short circuit immediately thereupon opened is given in Fig. 3. The steady value of the short-circuited current is I, and the transient value i is quite small. When the short circuit is removed, it may be noted that the generator voltage builds up to the open-circuit voltage, V, almost instantaneously.

This oscillogram proves that the transforming reactor fulfills its purpose in practically eliminating the transients, making the generator, during sudden changes of arc current, follow the regulation curves obtained under steady conditions.

To function ideally, this device should be designed in such a manner that the mutual induction between its two windings is the same as the mutual induction existing between the cross-magnetic shunt winding and the armature winding with its series winding.

Let N_1 = total effective number of turns on the cross-axis of the generator carrying the welding current.
N_2 = total number of cross-shunt field turns.
n_1 = number of turns on the transforming reactor carrying the welding current.
n_2 = number of turns on the transforming reactor in series with the cross-shunt field.
F = cross-flux per ampere-turn of the generator
f = mutual flux per ampere-turn of the reactor.

The design of the transforming reactor should then satisfy:

$$f \times n_1 \times n_2 = -K \times F \times N_1 \times N_2$$

The minus sign is used, since the two windings on the transforming reactor support each other, whereas in the generator corresponding windings oppose each other. In order to eliminate all transients, K should be equal to 1; however, fractional values of K give very good transient performance.

Experience has shown that to stabilize the arc, a certain amount of series reactance in addition to generator reactance is necessary in the arc circuit. This additional reactance is supplied by shaping the magnetic circuit of the inductive device so as to enlarge its primary leakage. (Fig. 2) Thus the transforming reactor has two fluxes; namely, the mutual flux which links both the primary and the secondary windings, and the primary leakage flux interlinked with the primary alone.

Experiments have shown that this combination welds with great ease both for hand and automatic welding. It lays down the metal with ease and accuracy under all conditions met in welding, and produces welds of uniformity and strength.

Electricity in Modern Dairy Plants

With the advent of the Electropure method of pasteurizing, in which electric current is actually passed through the milk, the modern dairy is taking its place among the important users of electricity. Other uses of electricity in such plants are also described.

By ***A. J. Dreux*** *and* ***H. C. Brunner***

Rieck-McJunkin Dairy Co.
Pittsburgh

Associate A. I. E. E.
Westinghouse Elec. & Mfg. Co.
East Pittsburgh

MODERN electrified dairies such as the main plant of the Rieck-McJunkin Dairy Company in Pittsburgh should be of particular interest to electrical engineers especially since the power survey recently made in that plant on the question of purchased power *vs.* gas and steam-engine generation. The desirability of the electric load for such a modern dairy plant is indicated by the fact that under the proposed operation, the average monthly power consumption would be 242,965 kw-hr. at 94.2 per cent power factor. The load demand is quite uniform throughout the year as indicated by the fact that the greatest maximum monthly demand is 962 kva. and the average maximum demand is 887 kva.

Under the proposed operation, all d-c. motors with the exception of those operating elevators would be replaced with three-phase, 60-cycle, 220-volt motors. Existing steam- and gas-engine-driven generators would be shut down and the present total electrical requirements purchased from the Duquesne Light Company, by whose power and steam survey division the study was conducted. Data and comparisons presented in this report indicate an annual saving of approximately $7,500 in favor of purchased power over present steam and gas-engine operation in which the annual power-plant operating charges are approximately $175,000. This saving is due principally to reductions in coal, labor, gas, and repairs.

Under present operation, the 680-ton capacity of refrigerating machines, and most of the power-plant auxiliary equipment, is steam-driven, and no immediate change in this arrangement is being considered by the dairy. The power survey therefore did not include a study of advantages obtainable by the electrification of this part of the plant although a few brief comments on the subject are included in this article.

Plants such as the Rieck-McJunkin main plant will average about fourteen receiving stations where the milk is cooled and fed to large heat-insulated tank trucks. The electric motors installed in each of these stations will total from 25 to 75 hp., depending upon whether or not the station also has milk-condensing equipment, butter churns, or ice cream equipment.

Upon arrival at the main plant, the milk (after recooling) is fed by gravity into the pasteurizing room, (Fig. 1) and collects in two small constant-level tanks equipped with float valves. The equipment shown in Fig. 1 occupies floor space of 18 by 30 ft. with a maximum height of 10 ft., and consists of six Electropure

---

From "A Modern Electrified Dairy Plant," (N . 31-58) presented at the Middle Eastern District meeting of the A. I. E. E., Pittsburgh, Pa., March 11-13, 1931.

units which pasteurize and cool to bottling temperature (40 deg. fahr.) 13,200 qt. of milk per hour.

In the Electropure process, pasteurization is accomplished by an electrical-conductivity method by actually passing electric current through the milk. The heat of pasteurization is generated within the body of the milk itself during the time the milk is being pumped through a rectangular chamber, the ends of which are formed by two carbon electrodes. These electrodes are connected to the conventional 220-volt power supply and for a 2,200-qt.-per-hr. unit, they are 32 inches long and four inches wide; they are spaced three inches apart. Such a unit consumes 48 kw. per hour.

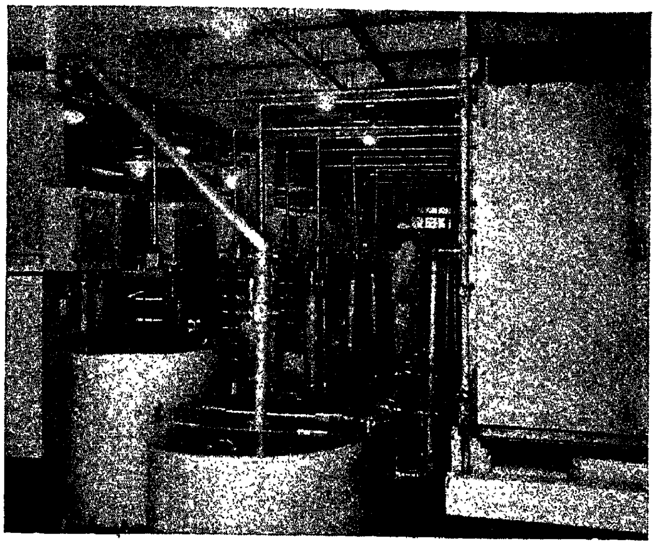

Fig. 1. A pasteurizing room equipped with six 2,200-qt. per-hr. Electropure process units

Electrical resistance offered by the milk to the flow of the electric current causes the temperature of the milk in the electrode chamber to be raised quickly. If either this electrical resistance of the milk or the power-supply voltage changes, the amount of heat generated within the chamber will change. In actual operation both are varying continually, and some means must be provided for regulating accurately the rate of milk flow to compensate for these, and to maintain a practically constant temperature at the outlet of the chamber. In addition, it is necessary to compensate for changes in the temperature of the raw milk supply. Limits of the practical operating range are set at the low-temperature limit by health codes, and at the upper limit, by the critical eye of the housewife. If the temperature drops too low, pasteurization will be incomplete; if the temperature rises too high, the amount of cream showing in the top of the milk bottle will be decreased.

On the six units shown in Fig. 1 the electrode chamber outlet temperature is regulated by means of a hand-operated micrometer valve and a controller which provides three speeds for the milk-circulating pump. The units in Fig. 2 are equipped with recently-developed supervised automatic control. This supervised automatic control was developed by Westinghouse to simplify the operation of the process, eliminate the possibility of human errors, secure an accuracy of temperature control not dependent upon the skill of the operator, and make unnecessary constant attention by an attendant.

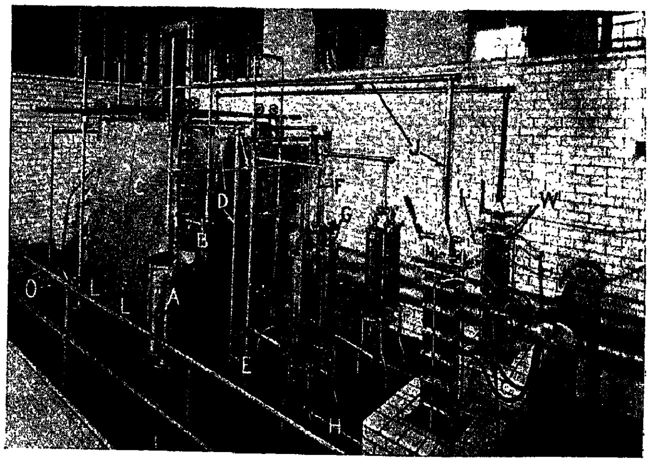

Fig. 2. Recent Electropure process installation equipped with supervised automatic control

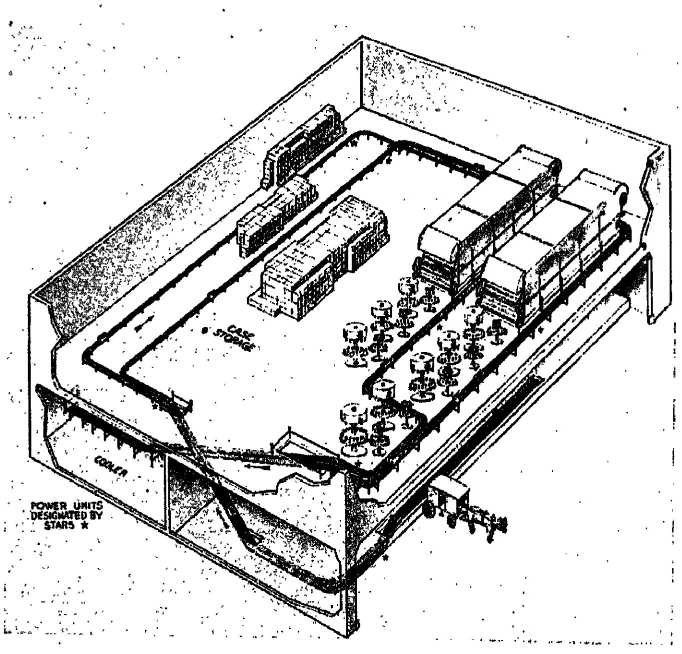

Fig. 3. An automatic case conveyer driven by eleven 2-hp. motors, conveys the returned empty cases to the bottling department and then to the cooling room

Should some abnormal condition cause undertreated milk to be circulated in the units equipped with these recently-developed controls, the control automatically stops the circulating motor and indicates to the operator what has occurred so that he may make the adjustment necessary to return the system to normal operation. This means that the operator may spend practically all of his time on other work; and since the control is accomplished entirely by adjustments in the electrical circuits, the control station may be located in a laboratory or any other room adjacent to the pasteurizing room.

In the Rieck-McJunkin plant, the cooled milk flows from the Electropure units to the bottle fillers by gravity, an automatic chain-conveyer system feeding fresh, clean bottles to and from the fillers (Fig. 3). This conveyer system is driven by eleven 2-hp. squirrel-cage electric motors, and its installation enabled the dairy to handle the same amount of milk in two hours less time with eight less men and two less bottle fillers.

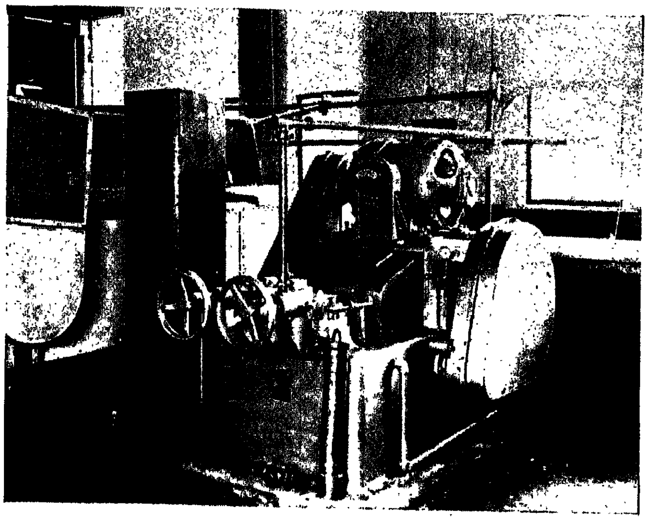

Fig. 4. An ice cream homogenizer which in reality is a special form of high-pressure pump. It is equipped with an ammeter to indicate the operating pressure

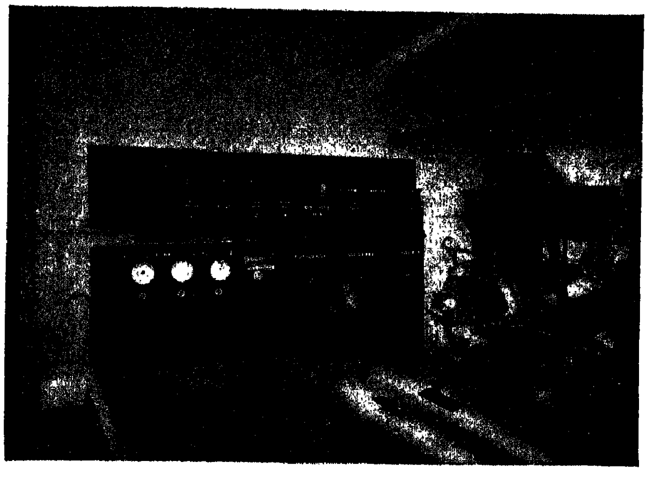

Fig. 5. Drawrite freezer meters and controls for regulation of the ice cream freezing process

The other milk products are obtained by similar careful processes, the details of which will not be given here. A few illustrations of the more important machines are presented, however, and their power requirements and load characteristics mentioned so as to give a more complete picture of the electrical apparatus.

The homogenizer (Fig. 4) is in reality a high-pressure pump which, depending upon its size, will require a motor of from 15 to 40 hp. By forcing the ice cream mixture through a specially designed orifice, this machine produces ice cream of even and fine texture.

In the freezing of ice cream, electric meters (Fig. 5) are used to record the freezing action. As the mixture freezes, the motor load increases; when the cream is properly frozen, the refrigeration valve is closed. The freezing is stopped, but the mixing continues until the whipping action has incorporated the correct amount of air to give the desired light, creamy appearance. This is known as the "over-run," and since the motor load decreases during this period the correct amount of whipping is also indicated by the meter.

Electrically-driven delivery trucks are frequently used by some of the large dairy plants, particularly those in cities where the routes are level and few hills are encountered. The ease of controlling the truck from either side, and the absence of gas fumes, make this type of truck especially desirable. Two 200-kw. motor-generators with a panel board (Fig. 6) are used for charging the batteries of trucks operating from a large Chicago dairy of approximately the same size as the Rieck-McJunkin plant.

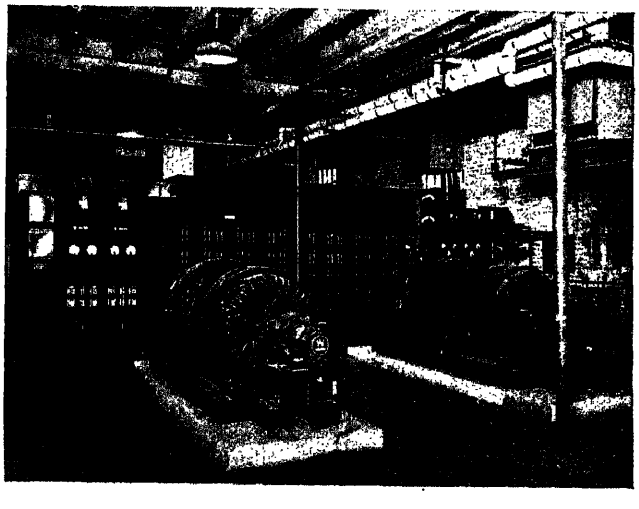

Fig. 6. Two 200-kw. battery-charging motor-generator sets and switchboard installed at the Borden dairy plant in Chicago for charging the batteries of electric milk-delivery trucks

Cracking Oil by Electricity

Low-grade oils formerly wasted now are "cracked" to form gasolines and other highly volatile oils. Some of the problems encountered in developing a reliable electrical process for accomplishing this are discussed in this article.

By Herbert R. Rowland

Member, A. I. E. E.

Moody Engineering Company, New York

FOR MANY YEARS, in this country and abroad, attempts have been made to use either silent corona discharge or the electric arc for the breaking up of heavier groups of hydrocarbons into lighter groups. It now is practical to manufacture gasoline by the corona method, the resulting product being a high-grade motor fuel.

In the cracking operation, heat must of necessity be supplied. When the electric arc is used heat is naturally furnished by the arc but is so intense that undesirable elements are formed which cannot be removed except at considerable loss and expense. When the corona method is used the amount of heat dissipated is too small to carry on the cracking operations and therefore heat must be supplied from some other source.

Probably the most consistent operations in electrical cracking have been carried on during the past thirteen years in Kansas City. This work was started using coronas produced by means of high-frequency circuits, but for many years insufficient gasoline was produced to prove the industrial or commercial worth of the process. This was due to two major causes; namely, the frequent breakdown of insulators resulting from the high temperatures used for vapor-phase cracking (900 to 1,150 deg. fahr.) and the extremely high power consumption which was due to losses in the attendant high-frequency apparatus, the over-all electrical efficiency of which was less than 0.5 per cent.

At this point in the development about seven years ago the writer was assigned the task of carrying on this work. At the outset it appeared both useless and unnecessary to continue with the costly and inefficient high-frequency method for producing the silent corona discharge.

The bibliography of the matter seemed to show quite conclusively that the voltage required for corona formation and silent discharge was governed mainly by (1) the size and composition of the wires or surfaces between which this silent discharge takes place, (2) the distance separating these two surfaces, and (3) the vapor tension of the enclosed medium.

Before making any major change in the characteristics of the electric circuit then in use, the writer consulted with the late Dr. C. P. Steinmetz, to whom he wishes to give full credit for the ideas, encouragement, and assistance he received from this conference. Early it was seen that the major part of the problem was concerned with voltage and insulation. Voltage required for silent corona discharge was found to be dependent upon both the size and composition of the wires or surfaces on which the phenomenon was to take place.

Steel, copper, nichrome, tungsten, and metal combinations, all have their different corona voltage characteristics. Other conditions being satisfied, metallic tungsten wire probably produces corona at a lower voltage for a given diameter than any other metal. However, due to its liability to oxidize when heated in an atmosphere containing even a small amount of air it was not suited for this work.

Nichrome-steel wire due to its extremely high elastic strength and its resistance to oxidation when heated in the presence of air was adjudged the most suitable metal.

The other side of the electric circuit consisted of the inside of a 12-in. pipe, it being necessary to handle in a completely enclosed system highly superheated volatile and explosive gases, such as vaporized oils.

The corona wire must be axially in the direct center of the reaction tube. Therefore it must be centered at the top of the tube by some type of insulator and at the bottom of the tube by another insulator which would hang as a weight on the wire, keep it axially taut in the tube, and prevent movement which might be caused by the flow of the vapors in the tube. A weight of ¾ lb. was found to be sufficient to keep the wire taut. It was finally found that No. 26 B&S gage was the smallest nichrome-steel wire that would support the ¾-lb. weight without stretching when heated to a temperature of 1,300 deg. fahr. This size and type of wire was therefore selected as possessing the best obtainable combination of the mechanical and electrical properties required for this work.

The next problem consisted of the selection of a suitable insulator; with proper allowances for safety factor an insulator for this work must meet the following severe requirements:

1. Operate continuously at 37.5 kv., 60 cycles without puncture.
2. Withstand a 45-kv. flashover.
3. Must be made of smooth material and built without petticoats so as not to have lodging places for local deposits.
4. Must not change shape or form at temperatures as high as 1,350 deg. fahr.
5. Must withstand this temperature on the bottom half, the upper half being at room temperature, without cracking.
6. Must have sufficient mechanical strength to prevent crushing when fastened securely in a stuffing box against hot vapor pressure.

From a paper informally presented before the A. I. E. E. Kansas City Section, April 22, 1930.

A study was made of the various materials from which an insulator of the foregoing requirements could be safely and economically manufactured. Glass, lava, and porcelain were tried, but it was found that these substances punctured at temperatures only slightly higher than the boiling point of water. These substances had a further extremely bad fault in that the part protruding from the reaction tube and projecting into the air, cracked and broke off when the part remaining in the tube was heated.

As a last resort fused quartz was tested and while the puncture temperature was only about twice that of other materials, the outer end of the quartz tube would not crack and break off when the enclosed part was heated to a high temperature. As long as the quartz was mechanically sound it was thought that if the insulator were made large enough it would act as a filler for an air-gap distance which would itself be of sufficient width to prevent a discharge between electrodes.

Accordingly many runs were made on enlarged insulators and while some of them operated satisfactorily for nearly 100 hr., others would puncture in less than 8 hr.

In order to separate the two electrodes still further the next step was to set the quartz insulator in a disk about 8 in. in diameter and one inch thick. While a combination of the tube and disk prevented puncture, in order to prevent leakage of the vapors past the disk it had to be placed in a stuffing box. Here it was found that quartz when heated and held firmly in one dimension would give no trouble from thermal expansion, but if confined in more than one dimension would shatter when heated. After several of these disks had broken, resulting in serious fires, this idea was abandoned.

Continued investigation led finally to the adoption of an oil-cooled insulator as shown in the accompanying illustration. As may be seen, this insulator consists of a tube of clear quartz of sufficient length to prevent flashover, enclosed over a part of its length in an envelope made from a larger diameter of quartz tubing. This outer envelope is fused to the inner tube at the bottom, the top being left open. Cooling oil is circulated in the annular space between the inner and outer tubes. An annular rubber cork is inserted in this space at the top of the outer tube through which two metal tubes sealed with a special cement extend into the cooling chamber.

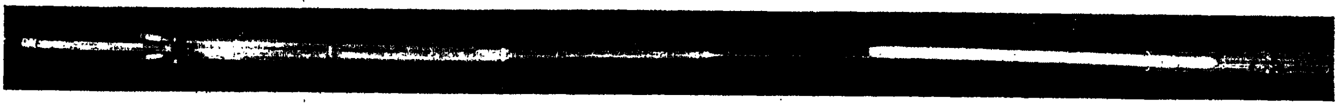
The outer ends of the tubes carry threads that will fit a ⅛-in. pipe-thread union. To these are connected well annealed copper tubing through which the cooling oil is led to and from the insulator. To prevent possible short-circuiting or electrical rupture on account of the metal tubes, a long piece of bakelite tubing is installed in each tube circuit which effectively breaks their electric continuity.

The central electrode runs down through the inner quartz tube, this electrode being made of flexible copper wire and brazed to the corona wire; this in turn is fused into the quartz, thus making a vapor-tight joint.

An insulator for use at the bottom of the reaction tube presented a much simpler problem, it was necessary only to provide sufficient weight to keep the wire taut and enough length to prevent flashover. This insulator has been made in two parts; a strip of metal containing a proper sized hole is first welded on the inside of the reaction tube so as to bring the hole directly in the center of the tube; into this hole is slipped a quartz thimble. Fastened to the corona wire is a quartz tube approximately 18 in. long, loaded with quartz sand until it weighs exactly ¾ lb. This tube is slipped through and hangs loosely inside of the thimble. The combination of tube and thimble gives great flexibility, combines a long flashover length with a small air-gap, and in case of any variation in the thermal expansion of either the reaction tube or the wire permits automatic adjustment. This combination has given no trouble except in those cases where the corona wire broke.

Apparatus for supplying high voltage is extremely simple; a 33-kv. step-up transformer is used connected on the low-voltage side directly to 220-volt, 60-cycle mains. This transformer contains sufficient built-in reactance so that in case of a short circuit on the high-voltage side there would be no abnormal rush of current. One high-potential lead is connected through disconnect switches to corona wires in the various reaction tube insulators, the other lead being connected directly to the reaction tubes and solidly grounded. A voltmeter connected across the primary terminals of the transformer, which ordinarily reads the impressed e. m. f. will read zero thus giving an indication of trouble in case of a punctured insulator or when a broken corona wire touches the surface of the reaction tube.

It is not thoroughly understood just what part this



Insulators for oil cracking by the silent corona discharge method. In service the assembly normally hangs suspended from the left-hand end as shown here silent corona discharge plays in the cracking process; however, three theories have been advanced as follows:

1. More perfect ionization of the vapors is produced by the corona discharge and therefore a more complete cracking takes place. This is known as the electrothermal theory.

2. Corona discharge sets up an agitation of the vapors and a possible electronic bombardment of oil atoms against the hot walls of the cracking tube, thus insuring a more perfect heat cracking. This is called the electromechanical theory.

3. The electroprecipitation theory, according to which gasoline is precipitated by the corona from the other vapors in the tubes, thus causing a clearer separation of the gasolines from the uncracked oils.

Since the amount of power used for five tubes handling a total of ten barrels of oil per hr. at a power factor of not more than 10 per cent is less than one kilowatt, this appears too small to accomplish a great deal of ionization. In the case of the electroprecipitation theory it seems impossible to precipitate a vapor from a vapor, since in these tubes at the temperature maintained all of the oil passing through must be in vapor form.

On the other hand it seems entirely feasible, to consider an electron moving through an appreciable distance in space and either carrying with it or driving before it a molecule of hydrocarbon in the vapor form. At last a surface is reached which permits no further movement of the oil vapor molecule, but which readily absorbs the electron. The impact of this molecule can be very great and the pressure at impact can run into large amounts, thus causing cracking by both pressure and heat when the force is expended against the hot wall of the reaction tube. It therefore seems that the violent agitation of the vapors by the silent corona discharge is undoubtedly of prime importance in the complete cracking of the vapors. These facts would tend to support the electromechanical theory.

The gasoline produced by this process constitutes in itself, without blending the saturate, unsaturate, and aromatic groups, a fuel that has not only high antiknock value but also more miles per gallon than "doped" fuels.

Field Test on Thyrite Arresters

A study of the performance of Thyrite lightning arresters when subjected to artificial lightning discharges of 1,500,000 volts has been made. The results obtained under different operating conditions are discussed in some detail.

By K. B. McEachron and E. J. Wade

Member A. I. E. E. Associate A. I. E. E.

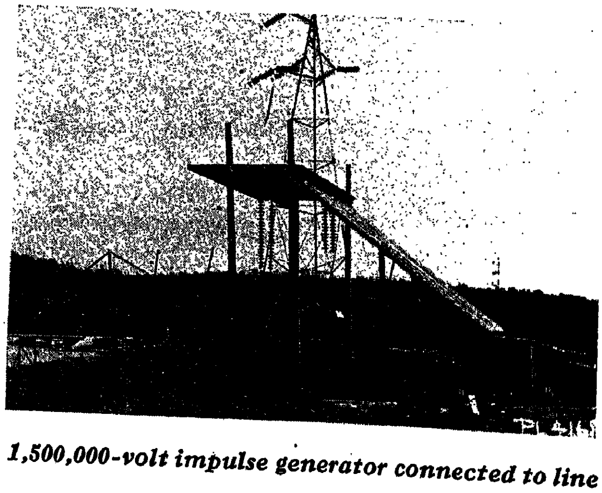
General Electric Company
Pittsfield, Mass.

STUDIES with natural lightning determine the form of waves which may appear in service, while artificial lightning (since it can be repeated at will and studied completely) is best used to disclose the performance of lines and apparatus.

During the last two years, investigations have been made in cooperation with the Consumers Power Company on their S-19 line which is about 45 mi. long. Various subjects were studied but this paper deals only with the tests made on lightning arresters during the summer of 1930.

A portable cathode ray oscillograph was especially designed for this work by one of the authors (E. J. Wade). It is of the cold-cathode type and incorporates many features making for rapid and reliable operation.

The impulse generator was located at the end of the line and consisted of 60 banks of oil capacitors, each of 0.5 μf., and charged in parallel to 25 kv. The open-circuit voltage when discharged in series was 1,500,000

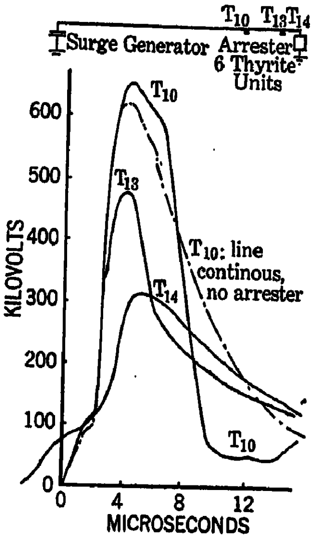


1,500,000-volt impulse generator connected to line

From "Field Tests on Thyrite Lightning Arresters," (No. 31-11) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

volts. The lightning arresters being studied were located 1.5 mi. away from the impulse generator. This distance was chosen as being far enough to give true traveling-wave conditions but not far enough for the waves to be reduced too much by attenuation.

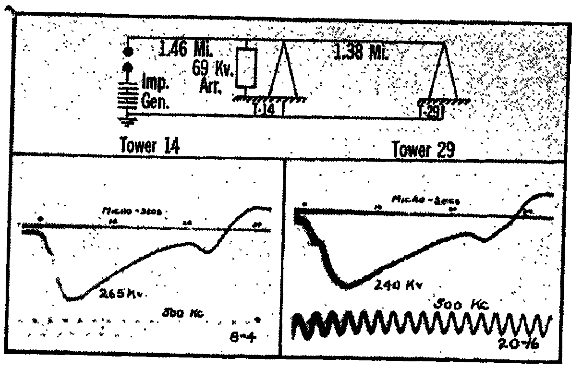
Methods of calculating the performance of the Thyrite arrester under any assumed condition have been developed and the first tests were made to check these calculations for ratings up to 220 kv. under three line conditions; *i. e.*, line continuous, line open, and two lines in parallel. These correspond respectively to the arrester being located at a point on a line, at the end of a single line, and connected to a bus with two outgoing lines. The agreement between the test results and calculated values is very good. It was found justifiable to add the ground resistance in calculating the arrester performance. If the arrester and apparatus grounds are bussed together the protection will be independent of ground resistance.



Impulse wave-shape at points between generator and arrester. Note that protection does not extend far beyond the arrester

The effect of a flashover on the line before the wave reaches the arrester is an interesting condition which is met with very frequently in practise. Tests were made to show what happens both without any arrester and with a 69-kv. arrester located three spans beyond the flashover point, which consisted of five insulator disks. When the arrester was connected, the flashover was delayed two and one-half microseconds and the oscillations were effectively suppressed. The point of flashover was too far away to be protected by the arrester.

Another series of tests of great interest was the measurement of voltage at various distances from the arrester. It was found that arrester protection does not extend much beyond 500 ft. for the wave used. Even if the arrester had reduced the potential to zero the zone of protection would not have been appreciably extended. The wave shape at distances beyond the arrester is the same as at the arrester, being changed only by attenuation.



Impulse wave-shape at points beyond the arrester showing that attenuation is apparently the only influencing factor

The question of arrester location and length of connections is of fundamental importance, and a number of different arrangements was tried. These included the so-called "hair-pin" loop, connecting the arrester in one or two stacks, long arrester connections versus long transformer connections, and the effect of a capacitance to simulate station apparatus. All the results can be explained by giving proper consideration to the effect of circuit length. The effect of the arrangement and turns or bends in the circuit was shown to be negligible.

It is of primary importance to locate the arrester close to the apparatus to be protected but if it must be at a distance, it is better to have long transformer connections rather than long arrester connections. This is because with long arrester connections the transformer reflects the incoming wave, while with short arrester connections, the transformer reflects only the arrester potential. The excess voltage which may be introduced by a certain length of connection does not depend upon the arrester rating; however while a given increase in potential may be considered negligible on a high-voltage arrester protection offered by a low-voltage arrester may be insufficient.

This investigation shows that Thyrite arrester performance for any given impulse wave can be closely calculated if the length of the connections and the ground resistance are known. Several hundred oscillograms have been taken, making available much valuable information regarding the application of lightning arresters.

These tests are part of a large program of transient investigation conducted jointly by the Consumers Power Company and the General Electric Company. The field work was in charge of E. J. Wade and J. R. Eaton, who were assisted by Messrs. W. J. Rudge, O. Brune, C. C. Tanner, E. J. Shimek, D. Blackwell and others.

Vertical A-C Distribution Networks

With buildings from 500 to 1,000 ft. in height becoming common in large cities, load densities have increased to many times their former values. Vertical low-voltage networks supplied from transformers located on different floors of these high buildings, are well suited to cope with such extreme concentrations of load.

VERTICAL NETWORK SERVICE was first offered by companies comprising the New York Edison System in December 1928, at which time the arrangement was accepted by the owners of the Irving Trust Company building at 1 Wall Street as suitable for the electric supply to that building. Similar arrangements were made almost simultaneously with several other large buildings which at that time either were being planned or were under construction. Since then, this type of service has been adopted for practically all new buildings in New York City, of more than forty stories, as well as for some lower structures. A few high buildings of the tower type having comparatively small floor areas have been built recently, but in these cases there is only a slight advantage in this specific service.

On January 1, 1931, there were in Manhattan ten completed buildings with vertical network service completely installed, comprising a total connected load of about 31,700 kw. Seven more buildings incorporating this service are now under construction. In these the total connected load will be about 14,300 kw. In addition, five new buildings are being planned with power and lighting requirements totaling about 30,000 kw., and in these it is expected to use the vertical network systems. The accompanying table gives detailed information regarding typical installations.

HIGH-VOLTAGE SUPPLY ABOVE THE STREET LEVEL

For densely-loaded urban areas in many localities a-c. distribution in recent years has taken the form of multiple-feed networks. The first installation of this type in New York City was completed in 1922. This arrangement provides an economical and reliable system which satisfies the electrical distribution requirements of most urban districts. In many cases these networks are of the three-phase, four-wire type, and are operated at 120/208 volts. Distance from the distribution transformers over which energy at such voltages can be economically transmitted, however, is definitely limited if both a reasonable amount of copper for distribution and satisfactory regulation are to obtain.

In a number of cities there has been a decided tendency in recent years to increase the height of buildings; this has resulted in an increase of total floor area to many times the ground area, with a corresponding increase in the electrical density of distribution. While in these large buildings the electrical-load density per sq. ft. of floor area has increased somewhat, the percentage increase, of course, is much less than the increase in load density based on ground area.

While this load may be considered in the light of an extremely dense load at the street level, yet the area may be so located that it is cheaper in over-all costs to supply it from distribution transformers located in upper floors of the building than to supply the energy at 120/208 volts from the street distribution system. Thus it might be considered that the utility has been presented with the equivalent of a large addition to its territory. This will be understood readily when it is realized that building heights of from 500 to 1,000 ft. above the street now are becoming commonplace and such buildings require large banks of elevators, the motors of which are located in the upper stories of the building. Some of these elevators have motors ranging in size from 100 to 150 hp. for the higher buildings, with short period demands several times these values.

With such dense loads at an appreciable distance from the street level, it is found to be definitely economical in over-all costs to distribute with multiple high-voltage supplies feeding a low-voltage network throughout the building. This system is identical in principle to the street network system, as may be seen in the accompanying illustration.

ECONOMIC ASPECTS

Comparative estimates of building wiring costs for the Irving Trust Company Building mentioned previously, showed a saving of $35,000, for the vertical network system as compared with the system in which the service transformers are all located in the

basement. However, some modifications in plans were made at the request of the local inspection authority and all of the above estimated saving was not realized.

In the Empire State Building the network system has been applied to the individual floors. Four-wire 120/208-volt feeders from one or more centers of distribution, where they are fused, feed into a four-wire main, circling each floor. Unfused branch circuits are tapped off this main to feed one or more "bays."

With the radial system of building wiring, enough copper must be run from the house switchboard to each load group (say three floors, for lighting, elevator bank, or other motor group) to carry the maximum load of that group. With the network system using a tie bus between transformer banks, the advantage of load diversity is realized in reducing the amount of copper required. The utilization factor can be worked out by the known probability factors for the case (see Power Calculations for Elevators by the Method of Probabilities, *G. E. Review*, October-November 1930). This method applies not only to elevators but is applicable also to variable loads of any kind for which an "operating factor" can be determined. The fifteen-minute demand (r. m. s. value of the load over this period) on the usual elevator bank is about thirty-five per cent of the connected load. With the old radial system of wiring a separate feeder, or duplicate feeders, having at least the load capacity of the fifteen-minute demand on each bank must be run to each such bank.

OWNERSHIP OF EQUIPMENT

Since a distribution installation in a building cannot be considered as having the permanency of a street system, (it being subject to the whims of the building owners) and since it cannot be utilized for any service other than for that particular building, there is naturally a distinct limitation to the amount of investment that the utility company can make for such an installation. On the other hand, if the vertical distribution network is used instead of distributing throughout the building from street services the building owner realizes a definite saving in building wiring. It is thus reasonable to have a different division of expense for vertical distribution from that which would be used in the case of general distribution throughout a city.

The division used in New York is to have the utility company supply, and own and maintain the high-voltage cables and the distribution transformers with their associated network equipment. These are placed in position by, and at the expense of, the building owners in ducts and vaults supplied as part of the building installation. All low-voltage distribution conductors and ducts except the 120/208-volt a-c. network ties from the street mains to the first distribution point within the building are owned and installed by the building owners. While the building owners install the transformers and high-voltage cables, all connections are made by the utility company. In case the building is abandoned this division makes it possible for the utility company to recover all its equipment, and the costs incurred are not materially different from those in supplying the building directly from the street system. In the case of high buildings the cost of the wiring installation is considerably reduced. Certain expense, of course, is incurred in securing space for transformer vaults, but in most cases space yielding little of value can be used for this purpose.

LOW-VOLTAGE TIE CONNECTIONS

If all conditions of supply for vertical distribution were the same as those found in the common network system, the installations would be unusual only from the standpoint of establishing the division of ownership and maintenance between the building owner and the utility. However, as the types of installations made to date will indicate there are numerous conditions which cause these services to differ. The vertical networks

used so far may be classified as follows according to the arrangement of secondary connections within the building:

1. Isolated or spot networks, also called junior networks in which the energy used at any one point in the building is supplied solely from a plurality of step-down transformers at a singl location, there being no secondary ties to any other network.

2. Networks with untapped low-voltage ties wherein the ties connect to other sources and therefore a multiplicity of step-down transformers at any one location are not required. In this case, however, service has to b supplied from the one location over special utilization feeders in the same manner as with a spot network.

3. Networks with tapped ties, the ties being used to distribute load to the several floors between transformer locations.

Each of these types of installation has been used to meet conditions which existed at the time the installations were planned. None of the tapped ties has been installed without fuses. Recent installations, however, are being made with untapped and unfused ties, installed in conduit surrounded by two or more inches of concrete; and in such cases, the building service is supplied locally from each step-down location.

FUTURE CONSIDERATIONS

One of the advantages obtained with vertical network service is the ability to increase the electrical capacity in the building at any time without expensive reconstruction of the original wiring, since each of the several high-voltage cables supplying the building are required for mechanical reasons to have much greater load-carrying capacity than is needed to serve any of the buildings contemplated up to the present time. Of course, the installation of additional distribution transformers would be required either in existing vaults or at new locations nearer the utilization point than the existing vaults; and in addition there would be required the necessary utilization wiring to deliver the new energy to the places in the building where it would be used. Such a procedure is much simpler and less expensive than would be required if the increase were to be supplied from the street network.

All vertical high-voltage feeder installations planned to date have used a dry type of three-conductor shielded cable with an outside wrapping of steel wires with which the cable is held up at the top of its run. It is possible (and obviously desirable) that future developments should make it feasible to use standard types of high-voltage cables for this purpose.

Considering the operating experience in New York City covering a period of about two years, the vertical network installations being made, are regarded to be more than adequate for the service requirements now foreseen. Improvements in methods and in equipment which will simplify the wiring installation and reduce cost may be expected in the future as inspection authorities, architects, and supply company engineers become better acquainted with the special requirements of this type of installation.

A-C Network, Industrial Interconnections, System Grounding Are Subjects of Pittsburgh Meeting

IF HEAVY ATTENDANCE and widespread discussion are indicative of the success of technical sessions, then the Pittsburgh District meeting must be adjudged conspicuous in this achievement. Held March 11-13, 1931, with headquarters at the Wm. Penn Hotel, Pittsburgh, it was sponsored jointly by the Institute's Middle Eastern District and the Association of Iron and Steel Electrical Engineers. Official registration exceeded 450, and attendance at several of the sessions was more than 500.

Inspection trips carefully planned to supplement the technical sessions added materially to values and interest. On Thursday evening, March 12, a banquet and dance was held under the joint auspices of the meeting and the Engineers' Society of Western Pennsylvania (Pittsburgh). With W. B. Stellmire (General Electric Company, Pittsburgh) toastmaster, the three speakers on the banquet program were Wm. S. Lee, president of the Institute, Dr. L. A. Hawkins, (General Electric research laboratory) the "Larry" Hawkins of radio fame, and E. C. Stone, vice-president of the Institute's Middle Eastern District.

Important details of the technical sessions are given in the following items. A résumé of discussions will appear in an early issue of ELECTRICAL ENGINEERING.

A-C. Network Symposium Attracts Wide Attention

Two out of five technical sessions were devoted to six papers and extensive, prepared discussion pertaining to the development of the a-c. network in electric power distribution. Three of these papers dealt with the development of underlying theory, having to do with low-voltage electric arcs; the second group of three papers related to the physical and economic aspects of the network idea itself.

Discussing "Burn-Off Characteristics of A-C. Low-Voltage Network Cables," George Sutherland and D. S. MacCorkle, of the New York & Queens Electric Light & Power Company, described extensive tests made to determine the characteristics of the clearance of faults in different types of a-c., low-voltage-network, copper-conductor cables installed in accordance with present standards of underground construction. Upon analysis of their test results and other data, the authors reached the following conclusions:

1. If A 3,000-ampere current is available, faults in the class of point contacts occurring in single-conductor, low-voltage cables operating at voltages from 120/208 usually clear within a few seconds irrespective of conductor size.
2. Copper-to-copper faults in single-conductor, low-voltage cables usually clear at the point of fault within one minute or less (for example, 3,000 amperes on 4/0 cable).
3. Size for size, the burn-off characteristics of non-magnetic-sheath cables dropped at random in a trench are the same as those of cables installed in 4-in. non-metallic ducts.
4. The burn-off characteristics of multiple-conductor, buried, non-magnetic-sheath cables make that type of construction undesirable for low-voltage, a-c. network distribution.
5. Analyses show no appreciable difference between oiled-paper and rubber insulation in the explosiveness and inflammability of gases produced by lead-covered cables.

J. Slepian and A. P. Strom of the Westinghouse research laboratories presented the subject "Arcs in Low-Voltage A-C. Networks." They reviewed the information pertaining to the extinction of a-c. arcs at current zero, and defined arc-reignition characteristics and circuit-reignition characteristics. Based upon studies of arc-reignition characteristics of short arcs between metal electrodes and non-adjacent to installation, the authors concluded that such arcs are incapable of interrupting practical low-voltage a-c. network circuits. They ascribed the extinction of arcs in practical network cables to the deionizing action of gas blast arising from burning insulation. It is claimed that experiments with arcs in cables, and arcs between parallel plates remote from insulation in some cases and closely bounded by insulation in other cases, confirmed this view. The authors stated that inorganic insulating materials also may assist in arc extinction through the generation of gas blast arising from their decomposition. In this connection boric acid was found to be the most effective material. It was stated also that the charring of organic insulation may be expected to cause an insulation to lose its arc-extinction-aiding characteristics.

Laboratory results bearing upon the "Reignition of Metallic A-C. Arcs in Air," were presented by S. S. Attwood and W. G. Dow, of the University of Michigan, and W. Krausnick, of Ohio Northern University. The authors were in search of experimental evidence of the current-voltage-time relations that exist during the period when an a-c. arc between metallic electrodes passes through its cyclic current zero. Twenty-nine cathode-ray oscillograms revealing certain characteristics of these relationships were presented. The authors stated that during the current-zero period the arc-electrode voltage is determined by the circuit constant, and rises until the electrode voltage reaches the breakdown or reignition value determined by the deionizing influences at work while the arc is extinguished. Alteration of the circuit constants permits a variation in the rate of voltage rise, with a consequent change in the reignition voltage. In the opinion of the authors the action of a circuit breaker in extinguishing an arc is greatly influenced by the presence of adjacent load circuits and by the presence of distributed inductance and the capacity in the connecting lines.

Some typical applications of the network distribution idea to power distribution within tall office buildings were outlined by A. H. Kehoe of the United Electric Light & Power Company, New York, and Bassett Jones, consulting engineer, New York. This paper appears practically in full on pages 292-95 of this issue.

C. T. Sinclair and R. M. Stanley, of the Byllesby Engineering & Management Corp., Chicago, presented their design of "A Primary Network." The primary network was characterized by its proponents as setting up the means for system growth and expansion, very largely obviating the need of extensive and expensive system planning. The primary network described is similar in general characteristics to the low-voltage network, particularly in so far as the inter-connection of the secondary mains is concerned. The authors contend that in spite of the fact that two transformation steps are required in the primary network described, compared with the one required in the low-voltage network the primary network has economic possibilities which should be considered seriously for areas of medium-load density. Such a network now is in course of construction in the Pittsburgh area and many persons interested took advantage of an inspection trip arranged to demonstrate this feature.

"The Philadelphia A-C. Network System," was described by H. S. Davis, and W. H. Ross, of the Philadelphia Electric Company. The system in question consists of sectionalized primary-loop feeders supplying a fused-secondary network. At present there are twenty-four of these feeders in operation with a normal total operating capacity of 32,540 kva. The feeder peak thus far experienced was reported to have been 27,600 kva. As a a result of five years of operating experience, during which period normal load growth and developments have been cared for, the authors have reached the conclusion that the system adopted has proved amply flexible to meet changing conditions, and that operating experience has been completely satisfactory under all conditions including times of faults on the network or elsewhere on the system.

Symposium On System Grounding

"Present Day Practise in Grounding of Transmission Systems," was comprehensively outlined in a committee report presented by C. A. Powel of the Westinghouse Electric & Manufacturing Company, chairman of an A. I. E. E. subcommittee on grounding.

J. E. Clem, General Electric Company, in his paper "Reactance of Transmission Lines with Ground Return," presented an analysis of a theoretical circuit consisting of any number of line conductors in parallel with a return to earth, and any number of ground wires in parallel. The paper is an added contribution of this author toward simplication of the calculation of ground faults, an essential factor in the prediction of system stability limits. In addition to his analytical study, the author presented confirming field test data and suggested a method of predicting the impedance of the fundamental circuits of a conductor with a ground return.

A "Fundamental Basis for Distance Relaying on Three-Phase Systems," was described by W. A. Lewis of the Westinghouse company, and L. S. Tippett, formerly of the same company. As a result of an extensive investigation into the subject, and based upon equally extensive supporting mathematics, the authors reach the conclusion that:

1. Conventional methods of distance relaying are subject to errors other than those caused by fault impedances.

2. Such errors may be eliminated in relays protecting against line faults by the use of the proper delta-connection of current transformers or relays.

3. That such errors may be eliminated in relays protecting against ground faults by the use of voltage or current compensation.

4. The limitation of application of distance relaying is the error introduced by the presence of fault impedance, which affects both impedance and reactance relays, but each to a different extent.

5. Distance relaying may be made to approach even more closely the desired relaying ideal and that within the limits of its application it should give satisfactory protection regardless of generator capacity or system conditions.

Under the title "Power System Voltages and Currents Under Fault Conditions —Effect of Sequence Impedances" R. D. Evans and S. H. Wright of the Westinghouse company presented the results of an investigation of the general characteristics of power systems under unbalanced fault conditions, giving particular attention to the range of voltage and current that may exist under such conditions. The authors made their analysis by the method of symmetrical components, giving attention to the range of the sequence impedances of power systems. They presented numerous curves and in general gave their results in a form offering a direct comparison of the characteristics of different systems. As a result of their study the authors have concluded that on three-phase systems:

1. The currents and the voltages under abnormal conditions may vary over a wide range depending upon the sequence impedances and the location and character of the fault.

2. The line-to-ground voltage may rise to twice the normal line-to-neutral voltage, and the ratio of line and ground current to the three-phase short-circuit current may be as great as 2.0 and 3.0, respectively.

3. The ground current on a double line-to-ground fault may be 50 per cent greater than the maximum value of a single line-to-ground fault.

The authors stated further that the range of voltages and currents on actual systems is determined principally by the ratio of the zero-sequence impedance to the positive-sequence reactance. They considered the zero-sequence-impedance ratio as a convenient criterion in connection with system grounding, and suggested that the preferred value of this ratio is in the range of from 1 to 4.

"Simultaneous Faults on Three-Phase Systems" were most ably and mathematically discussed by Miss Edith Clarke of the General Electric Company. The author extended the method of symmetrical components to apply to a three-phase system during simultaneous faults at two or more points of the system, and developed a general equivalent circuit replacing (in the positive-phase diagram) two simultaneous faults involving any combination of the six conductors. Further applications of the general method were discussed, and numerous typical cases were worked out in detail by the author, who stated that the methods and formulas given in her paper were developed in answer to such questions as:

1. Which is the more severe shock to a system, a double line-to-ground fault in one circuit or two single line-to-ground faults occurring simultaneously on two separate circuits?

2. Do simultaneous double line-to-ground faults which involve the same phases (*a* and *b*) on two circuits result in more, or less ground current than do faults which involve phases *a* and *b* on one circuit and phases *b* and *c* on the other?

Industrial Power Applications

Power usage, particularly as it affects power supply for large industrial establishments, was the central theme around which was built an important program for a joint session with the Association of Iron and Steel Electrical Engineers, and sponsored by that organization. Many significant phases of some of the more important problems arising from heavy-duty electric power interconnections between large industrials and the electric utilities were treated in the light of both engineering and economics by the several papers and by most of the large number of prepared discussions presented at the session. Perhaps the most vital single point brought out in the entire session was the fact that such interconnections, whether for one-way power supply or for the interchange of power between utilities and industrials, must show definite advantages and profits to both parties if such contacts are to remain in force for any length of time.

F. O. Schnure, of the Bethlehem Steel Company, outlined the three interconnection plans now in common practise as:

1. Where the utility furnishes all the power used by the industrial.

2. Where the utility furnishes peak power for the industrial with the latter supplying its own base load.

3. Where the utility furnishes the base load for the industrial, with the latter supplying its own peak power.

The author gave as a fourth possibility, that in which the utility purchases from the industrial surplus power, and stated that in his opinion the greatest economies for each party are to be found in the potentialities of interchange.

Operating experiences arising from the interconnection between the Duquesne Light Company and the Davison Coke & Iron Company, Pittsburgh, were given in a paper jointly prepared by G. E. Dignan, chief engineer of the Davison Coke & Iron Company, and R. I. Kirk, Duquesne Light Company.

Under the title "Absorption of By-Product Power," A. Hoefle of the Toledo

(Ohio) Edison Company, and W. T. Woodmany, of the Interlake Iron Corp., said in part:

> Complete and economic utilization of by-product is an end much to be desired in modern industry. Studies that have been made with reference to such an end have frequently revealed promising opportunities for cooperation between manufacturing plants and electric utilities. Some combined arrangement often will prove to be of economic benefit to both parties.
>
> The basic idea in a coordination scheme lies in the construction of efficient stations to operate at a good load factor by feeding into the utilities' systems whenever the manufacturers' demands for steam or by-product power drop off. Some of the methods of accomplishing this result are:
>
> 1. Use in the utility's plant of industrial by-products representing excess energy.
> 2. Sale of exhaust steam supplied by a central station's generating plant to a manufacturing establishment for process purposes.
> 3. Transfer of excess power generated in the manufacturer's generating plant to a utility system.
> 4. A joint arrangement in which manufacturer and utility own and operate a generating station and share the fixed and variable costs in proportion to benefits derived.

The authors gave examples upon which they based their conclusions.

A detailed discussion of some of the many problems entering into the question of electric power distribution within a large industrial establishment was given in paper prepared jointly by R. D. Abbiss of the Carnegie Steel Company, and D. C. West of the Westinghouse company.

The application of electrically-heated annealing furnaces for steel and other industries was described quite completely by J. C. Woodson of the Westinghouse company. After describing present practises and considering current operating experiences with the equipment in question, the author offered the following predictions as to the future:

> 1. A rapid and extensive expansion of electric annealing to wire strip and sheet mills generally to meet economic limitations and competitive costs.
> 2. The use of artificial furnace atmospheres to secure special and better results in fabricating and manufacturing processes.
> 3. There will be developed more of the large continuous electric furnaces for sheet annealing and normalizing, and with artificial atmospheres.
> 4. An extensive development and application of the principles of inductive heating to numerous heat-treating processes now considered unsuitable.

"A Modern Electrified Dairy Plant" described in a paper prepared jointly by A. J. Dreux of the Rieck-McJunkin Dairy Company, Pittsburgh, and H. C. Brunner of the Westinghouse company reflected another important application of electrical equipment. This paper is presented essentially in full elsewhere in this issue.

Power Supply For Communication Systems

In describing "Automatic Power Plants for Telephone Offices," R. L. Young, American Telephone and Telegraph Company, and R. L. Lunsford, Bell Telephone Laboratories, laid particular stress upon the exceptionally high degree of reliability in electric power supply that is essential for a telephone system. They described in detail unit-type power plants that have been developed for telephone offices, and mentioned the fact that the operating reliability record of modern equipment of this type is 99.9996 per cent.

A description of similar equipment developed for telegraph service was presented by E. W. Griffith of the Western Union Telegraph Company, in his paper "Telegraph Power Plants." The author traced the development of telegraph power plants from the era of the gravity battery down to the present combination of automatic equipment and storage battery.

Radio communication came in for its share of the discussion with a description presented by R. L. Davis of the Westinghouse company covering the power equipment at the new high-powered KDKA broadcasting station, and a lucid description of "Recent Developments in the Operation of Overseas Radio Telephone Service," presented by F. A. Cowan, of the American Telegraph and Telephone Company.

Students Active at Pittsburgh Meeting

At the district conference on student activities held March 12, 1931, in conjunction with the Pittsburgh meeting of the Middle Eastern District, each of the first two subjects was presented by two speakers, one representing industry and one representing the student point of view:

SUMMER EMPLOYMENT FOR ENGINEERING STUDENTS
- W. D. Bruce, chairman, University of Pennsylvania Branch, and
- O. W. Eshbach, Personnel Department, American Telephone & Telegraph Company.

QUALIFICATIONS LOOKED FOR IN A CADET ENGINEER
- Harmon Shively, chairman, University of Akron Branch, and
- E. B. Roberts, Educational Dept., Westinghouse Electric & Mfg. Co.

These topics were discussed by many present, and the following resolution was adopted:

Be it resolved that:

1. In view of the continued industrial depression with the resultant inability of industry to absorb the 1931 graduates, the technical colleges in the Middle Eastern District be requested to present to the senior classes the desirability of continuing their educational program; and furthermore that the college authorities be requested to seriously consider extending as much assistance as possible to students capable of profiting by this program.

2. The Chairman of this Committee be charged with the duty of forwarding this resolution to the college governing boards in the Middle Eastern District.

The third topic, "Has the Student Branch any Responsibilities to Freshmen and Sophomores?", was presented by C. L. Lucal, incoming chairman of the Ohio State University Branch, and W. J. Lattin, incoming chairman of the Case School of Applied Science Branch.

Professor J. T. Walther, counselor, University of Akron Branch, and vice-chairman and secretary of the district committee on student activities, presented a comprehensive report on the Branch activities in the district during the present academic year. This was followed by brief reports by several speakers giving additional information concerning the meetings of certain Branches.

Eleven of the eighteen Branches in the district were represented by their counselors and chairmen, and two others by the chairmen only.

LUNCHEONS

Prior to the student conference a joint luncheon meeting of the counselors and chairmen was held. At this Professor Morland King presided and brief addresses were given by E. C. Stone, vice president of the Middle Eastern District; F. L. Hutchinson, national secretary; and Henry H. Henline, assistant national secretary.

Vice-president Stone stated that the fundamental purpose of the Branches is to make better electrical engineers. He emphasized the importance of contacts between students and electrical engineers, and the benefits to be derived by students from the preparation, presentation, and discussion of papers. Mr. Hutchinson and Mr. Henline also spoke of the benefits available to students who participate in Branch activities. Mr. Henline gave a brief summary showing the great increase in student participation during recent years.

Separate luncheons were held March 13 for the counselors and for the Branch chairmen. At the Counselors' luncheon, it was decided that the next district conference on student activities will be held in the spring of 1932 in conjunction with the annual student convention of the schools in and near Philadelphia.

Professor J. T. Walther, counselor of the University of Akron Branch, was elected chairman of the district committee on student activities; Professor Lewis Fussell, counselor of the Swarthmore College Branch, was elected vice-chairman and secretary, both to take office August 1, 1931.

Directors Meet at Pittsburgh Gathering

The regular meeting of the Board of Directors of the American Institute of Electrical Engineers was held at the William Penn Hotel, Pittsburgh, Pa., Thursday, March 12, 1931, during the Middle Eastern District meeting. Present were:—

President: W. S. Lee, Charlotte, N. C.—Past-president: R. F. Schuchardt, Chicago, Ill.—vice-presidents: Herbert S. Evans, Boulder, Colo.; W. S. Rodman, Charlottesville, Va.; E. C. Stone, Pittsburgh, Pa.; C. E. Sisson, Toronto, Ont.; G. C. Shaad, Lawrence, Kans.; H. P. Charlesworth, New York, N. Y.—directors: F. C. Hanker, East Pittsburgh, Pa.; E. B. Meyer, Newark, N. J.; F. W. Peek, Jr., Pittsfield, Mass.; C. E. Stephens, A. E. Knowlton, New York, N. Y.—National Treasurer W. I. Slichter, and National Secretary F. L. Hutchinson, New York, N. Y.

Ratifications

Minutes of the directors' meeting of January 28, 1931, were approved.

A report of a meeting of the board of examiners held February 18, was presented and approved. Upon its recommendation the following elections were made of applications pending: 290 Associates; 13 Members; one Fellow. Transfers: 40 to grade of Member, and six to grade of Fellow.

In accordance with Sec. 22 of the constitution, S. L. Foster, E. E. Keller, and Wm. Lispenard Robb were exempted from future dues, and their names added to the list of "Members for Life."

The finance committee's approval of February bills amounting to $31,161.18, ratified. Decision was made to accept the invitation of the Cleveland Section and hold the 1932 summer convention at Cleveland, Ohio.

The board confirmed the president's appointment of the following committee of tellers to canvass and report upon ballot of election for Institute officers: P. C. Jones (chairman), Henry Kurtz, E. J. O'Connell, Hugh L. Smith, W. Y. Vedder, E. Volckmann, and J. T. Wells.

L. A. Ferguson was reappointed the Institute's representative on the Commission of Washington Award.

For appointment by the president of the National Academy of Sciences, H. P. Charlesworth was nominated as a representative of the Institute on the Division of Engineering and Industrial Research of the National Research Council, to succeed Dr. F. B. Jewett, whose term expires July 1, 1931, reappointment denied.

An invitation for September 21-25, 1931 from the Royal Institution of Great Britain to send a delegate to centenary celebration of Michael Faraday's discovery of electromagnetic induction was accepted, and the president empowered to appoint delegate and alternate.

Invitation was accepted to send a delegate to the celebration October 1-2, 1931, at the University of Cambridge, England, commemorating the birth of James Clerk Maxwell. The board also accepted invitation to be represented at the inauguration of President Chase, University of Illinois, May 1, 1931.

Resolution was adopted expressing the board's appreciation of various Pittsburgh meeting committees, in their excellent arrangements for the meeting and the effective manner in which plans were carried out.

Other matters were discussed, reference to which may be found in this and future issues of Electrical Engineering.

◆ ◆ ◆

Some Winter Convention Discussions are Summarized—Part II

A SUMMARY of some of the many discussions presented at the last five sessions of the 1931 winter convention is given herewith. A similar summary covering some of the discussions presented at the first four sessions of the convention was given on pp. 226-228 of Electrical Engineering for March 1931. Only discussions submitted in writing in accordance with A. I. E. E. rules governing it is summarized; complete discussion together with all papers so approved will be published in the Transactions. A list of papers presented was published in the January issue of Electrical Engineering, pp. 52-53.

Industrial Power Applications

Electron Tubes

H. S. Phelps discussed the use of a photoelectric switch for control of street-lighting circuits. An operating test of this device has disclosed a close approximation to the municipal schedule in effect and it has extended both the night and morning scheduled lighting period on cloudy or stormy days.

J. V. Breisky in his discussion classified the various types of tubes in general, and in particular the family of grid-controlled gas-filled tubes which he subdivided into three groups; cold-cathode tubes, hot-cathode tubes, and tubes employing a pool of mercury for a cathode. The characteristics of each class were described. In conclusion Mr. Breisky predicted that during the next few years a tremendous increase in this activity would take place, particularly when the larger tubes become standardized and are generally available.

C. R. Sharp cited an important application of photoelectric cells and electron tubes; namely, the photometry of incandescent lamps. He explained that the caesium cell has red sensitivity and is applicable for photometric purposes when the color between the lamps to be measured lies within the ordinary range of commercial lamps.

Automatic Regulators

In connection with discussion of this subject, S. Minneci described a system of automatic control for load-ratio control wherein a contact-making voltmeter is used as the master element. The control circuit is arranged similarly to that used with induction voltage regulators except that an adjustable time delay relay is inserted between the contact-making voltmeter and the motor-reversing contactor at the operating mechanism.

R. G. Standerwick discussed the performance of hydraulic regulators on turbine installations. Charts were shown illustrating the regulation of a 10,000-kw. speed-regulated turbine tied in with a second machine of 6,000 kw. capacity and operating over a wide fluctuation of electrical load.

Plant Distribution Systems

G. S. Merrill in his discussion of the section of the paper dealing with general-purpose indoor lighting pointed out that interest, taxes, depreciation, and the cost of electrical losses, are elements in the cost of producing light that should be taken into account in determining how the maximum amount of light per dollar in a new installation can be obtained. For the case in the paper where energy costs 1½c. per kw-hr. lamps operated at normal voltage will produce light at a unit cost about 2 per cent lower than if they were operated 5 volts under their labeled voltage.

A. B. Smedley discussed the cable and wire phases of the subject with particular reference to non-metallic, sheathed, underground cables. He pointed out that cable manufacturers have done much development work in perfecting the nonmetallic materials and compounds. Particular attention has been directed toward the possible elimination of materials of high-thermal resistivity and the tensile strength has been greatly increased without sacrificing flexibility.

SPECIAL SYNCHRONOUS MOTORS

Fraser Jeffrey in discussion of the subject pointed out that notwithstanding the high cost of the so called synchronous induction motor and its use being restricted principally to high-speed drives, such machines are being successfully applied to low-speed high-inertia drives at costs competitive to other modified types of salient-pole machines.

F. K. Brainard in his discussion of the subject made comparisons between induction motors and synchronous motors within the various speed ranges. The comparison is usually favorable to the synchronous motor up to speeds of 1,200 r. p. m. although it depends largely upon the value of reactive kva. in the particular installation.

Transportation Session Discussion

SUBURBAN ELECTRIFICATION

H. M. Trueblood discussed the paper "Lackawanna Suburban Electrification" from the standpoint of inductive coordination because this is the first electrification in the United States using rectifiers as the sole source of propulsion power; the contact-wire voltage is 3,000 volts. He pointed out that the results of field tests conducted under severe conditions indicated that the Bell System plant which is located in close proximity would experience little or no difficulty from induction or ground potentials.

One of the points commented upon by W. B. Potter in his discussion of the same paper was the method of putting the air intake for motor ventilation at the top of the car, thereby eliminating much dirt and brake-shoe dust from the motors.

C. H. Lydall discussed the paper and described a 3,000-volt d-c. electrification in South Africa where at first considerable trouble was caused by lightning. Later, however, the trouble was eliminated entirely by the installation of high-speed circuit breakers on the feeders to the track.

H. F. Brown in discussing the subject "Motive Power for Suburban Electrification," indicated that the conclusions reached in Mr. Kerr's paper agreed more or less in all points enumerated with the results obtained by the New Haven Railroad during twenty or more years of a-c. operation of electric suburban traffic.

INCLINED-CATENARY CALCULATIONS

W. B. Potter discussed the subject and in his opinion the type of structure given in the paper does not provide for the same flexibility on curves as the chord system. The contact between the line and the collector is best assured by flexibility of the line.

H. F. Brown commented favorably upon the paper by saying that not only did it present a valuable addition to the meager literature existing on inclined-catenary design, but also it has simplified somewhat the calculations required both in the development of the shape factors, and in their application to the track alinement.

N. Litchfield in his discussion of the subject pointed out that the so called "curved" or "inclined" catenary was originated by the engineers of the New Haven Railroad in 1909. To accommodate longer spans with sharp curves, particularly transition curves, the original method of calculation was modified in 1913-14 by Messrs. H. S. Richmond and Philip Goldstone, and has become practically the standard method in general use. In conclusion it was stated that Mr. Picken's paper is well worked out and should be of interest to all catenary designers.

H. S. Richmond discussed the subject and stated that in his opinion equation (33) of the paper is not significant because the *U*-curve practically approximates the circle and most track curves are not actually so uniform.

J. B. Colley in his discussion of the subject outlined a method of calculation for the transition curve which he believed is shorter than the method given in the paper and although not so exact, seems to be within the bounds of practicability.

H. F. Brown discussed "Design of Catenary System for Cleveland Union Terminal." He drew attention to the temperature movements of the center of 250- or 300-ft. spans where a bronze messenger is used instead of steel messengers. He also commented on the use of chains for suspension and pull-off members, which he pointed out are subject to vibration, weather, and corrosion, and in the course of a few years are liable to wear very thin. In his opinion such parts should be reduced to a minimum.

Electric Welding Session Discussion

S. Dushman discussed "Arcs Between Metal Electrodes" stating that one of the most important results to follow from this investigation is the conclusion that the transition from the glow to the arc (or vice versa) is governed more by the current density at the cathode than by the temperature of the latter. He discussed the conclusions from the point of prevalent theories on the phenomena occurring in the transition from glow to arc and on the origin of electrons at the cathode of an arc discharge.

C. G. Found's discussion of the same subject was presented by Dr. Dushman. He commented on the paper as being a valuable contribution to the study not only of arcs but also of general discharges in gases, particularly the transition stages from the normal to the abnormal glow and from the abnormal glow to the arc.

J. Slepian discussed the paper raising the questions, (1) may not the transition states observed by the authors be only apparently equilibrium transition states? (2) May they not consist of very rapid alternations between the glow states and the high-current density arc state? He called attention to the fact that these alternations might take place with such high frequency as to escape detection on the oscillograph used by the authors.

A. Churchward discussed "An Improved Arc-Welding Generator" stating that early in 1924 he had used the transformer reactor on a self-excited drooping welding generator, and his tests confirmed the results in the paper.

D. W. Ver Planck discussed "The Neutralized Welder" and commented on the fact that the paper demonstrated that the steady-state and some of the transient characteristics of welding generators can be determined analytically. He was of the opinion that the equivalent circuit method which leads to the same results is considerably simpler than the method described in the paper.

D. W. Ver Planck also discussed "A System for D-C. Arc Welding." He presented a method of analysis which showed to what particular quality of the machine each part of the transient was due, and would suggest to the designer the way in which any part of the transient might be emphasized or suppressed. The current transient following a short circuit can also be handled in a similar fashion, though with somewhat less ease.

Research Session Discussion

H. H. Race discussed "Conductivity of Insulating Oils—II." He commented on the paper pointing out that the author deserves considerable credit for developing sensitive apparatus for determining short-time d-c. characteristics. The conclusions, if correct, will have a far-reaching effect upon the development of the theory of liquid dielectrics. Several reasons why the initial exponential portion might be due to an oscillographic error rather than a characteristic of the oil were given by H. H. Race in his discussion. He also inquired as to the meaning of "dielectric absorption" in connection with the results.

CABLE OILS

J. B. Whitehead discussed "Some Electrical Characteristics of Cable Oils." He pointed out that no quantitative relation had been found heretofore between the one-minute or long-time d-c. conductivity and the actual values of dielectric loss at various frequencies. He believed Dr. Race went a little too far in the suggestion in his paper that the one-minute d-c. conductivity is a sufficient indication of the a-c. properties of the oil.

One of the points discussed by W. B. Kouwenhoven in his discussion of "Electrical Characteristics of Cable Oils" was the curve in Fig. 6 showing the variation of resistivity of oil with temperature. He gave data on resistivities of two oils at 1,500 volts, taken at various temperatures at a voltage gradient of 25 volts per mil made at four mil-seconds to 40 minutes after the application of voltage. When these data are plotted on semi-log paper the 40-minute values fall on straight lines of a slightly greater slope than those given in the paper. The four mil-second values did not give a straight line relation when plotted as in Fig. 6. The resistance of oil varies not only with temperature but also with the time after the application of voltage.

In connection with the discussion of "The Conductivity of Insulating Oils," S. K. Waldorf replied to H. H. Race's questions concerning the oscillograms; he explained that the response of the apparatus to d-c. impulses was recorded and that it was shown that the oscillograph vibrator used was over-damped rather than under-damped and it did not over-travel. He also explained that deflections were measured to a tenth of a millimeter which on oscillograms having the smaller deflections gives a current value accurate to within about 5 per cent or better. With larger deflections, the accuracy of such measurements is of the order of 1 per cent and better.

C. L. Dawes discussed "Fundamental Properties of Impregnated Paper." He discussed the so called *V* or *U* curves of the power loss in impregnated-paper insulation as a function of temperature and pointed out the value of the paper in giving a definite explanation, (substantiated by experiment) for these curves.

TRAFFIC CONTROL BY LIGHT BEAMS

F. Hamburger, Jr. discussed this subject and in his opinion a twelve-second green light for minor street traffic where traffic is light was too long. He asked if it was not possible with the control described in the paper to set the minor street green for six seconds and provide a step-up feature or time extension to permit a longer minor street green in the event of several cars following one another?

COMMUTATION IN HYDROGEN

T. T. Hambleton's discussion of this subject was read by Mr. Linville. He reported results of tests made on a 3,000-kw., 10,000-ampere, 60-cycle, 300-volt, converter which was operated in a gas-tight enclosure of hydrogen. The results showed a reduction in windage loss amounting to approximately 25 kw. and an increased cooling efficient. The rating of the converter when operating in hydrogen could be increased 25 or 30 per cent with approximately the same ultimate temperatures in the current-carrying parts as were reached at the lower rating when operating in air.

NON-LINEAR CIRCUITS

V. Karapetoff discussed this subject and mathematically analyzed his conception of one of the series circuit conditions.

E. Weber discussed the subject and gave a fundamental analysis of the distortions shown in the waves of the current and voltage drops across the reactor and capacitance. His fundamental analysis showed that this phenomenon is quite in accord with ordinary series resonance of the double-energy linear circuit, and differs only in that it exists for only a small part of the period.

Electrical Machinery Session Discussion

C. R. Boothby discussed "Induction Motor Slot Combinations" and brought out that while appreciable "hooks" are indicated in many of the speed-torque curves shown in the paper, for most commercial applications these would not be unsatisfactory. Combinations which are noisy at low speeds often are very quiet at normal operating speeds.

H. C. Specht, in his discussion of this same subject, (read by C. R. Boothby) doubted if the theory of revolving permeances was any more useful in simplifying the problem of noise and cusps in the speed-torque curves of induction motors. He commented upon a number of the rules given in the paper and believed that the reader would profit a great deal more from the valuable data given if it were clearly shown how the ten rules were derived from the mathematical work.

L. A. Doggett also discussed the paper and expressed hope that the author would go a step farther and give tables recommending the number of slots for the more common cases. Upon trying to apply the rules given by the author to the case of a two-pole, three-phase machine it was found that all possible values of rotor-slot numbers were eliminated by one or more of the ten rules.

THE PULLING INTO STEP OF A SALIENT-POLE SYNCHRONOUS MOTOR

D. W. McLenegan and I. A. Terry discussed this subject and commented on the value of the M. I. T. integraph in solving problems which are very difficult to treat analytically. They described tests on a 75-hp., three-phase, 900-r. p. m., 0.80-power factor, synchronous motor to determine the effect of the field time constant upon the pull-in characteristics. Results of these tests show that due to ideal timing of the instant at which the field is applied a motor may pull into step from a slip greater than that indicated by formula (5) in the paper.

V. Bush discussed the paper with particular reference to the integraph and the stroboscope. He explained that a new integraph was now under construction which would be capable of solving total differential equations of very considerable complexity and with much better precision than was possible with the present machine. He also commented on the new stroboscope and the very large light intensities produced. He explained that Mr. Edgerton used a stroboscope which had a period of illumination of only about 10 microseconds occurring once each cycle and yet was able to obtain sufficient light for photography.

HEAT LOSSES IN LARGE TURBINE GENERATORS

C. J. Fechheimer discussed this subject and commented on the complexities of the problem. He pointed out that by modifying the boundary conditions the author has simplified his solution and has put it into workable form by substituting equivalent electrical circuits for the heat circuits.

K. K. Palueff discussed the paper and described how a short-circuit table such as is used for the analysis of short-circuit characteristics of transmission systems could be employed to solve thermal problems similar to those mentioned by the author.

One of the points discussed by D. S. Snell in his discussion of the subject was the assumption made in the paper that the plane of division of radial heat flow in the tooth region is at the bottom of the slot. He pointed out that while this assumption is justifiable for turbine generators with radial ventilating ducts in both stator and rotor, it might give temperatures very much higher than the actual for turbine generator rotors of the solid-forged type with ventilating channels below the coil slots.

THE NON-RESONATING AUTO TRANSFORMER

F. J. Vogel discussed this subject and one of the points which he brought out was that experience in the design of transformers has indicated always that practically the entire surge voltage is across the series part of the winding whether or not the low-voltage line is connected; and good insulation practise has been established on this basis. He also discussed interleaved windings and submitted a figure which shows the initial distribution and oscillations within the winding. All the stress is distributed over the series part of the winding and high voltages do not prevail at points of discontinuity as claimed in the paper.

◆ ◆ ◆

Rochester Meeting Features Noise Abatement and Lightning Studies

An attractive program consisting of four technical sessions and entertainment with a special program for the ladies and a number of interesting inspection trips has been arranged by the Local Committee for the meeting of the North Eastern District of the A. I. E. E. to be held at Rochester, April 29 to May 2. Headquarters will be at the Sagamore Hotel.

Because of its location Rochester is readily accessible from all points in the East and is possessed of scenic beauty of unusual interest. It is particularly noted for its fine residential sections, being known throughout the Empire State as the "city of homes." Also of importance is its manufacturing center; several of the large plants located in the city will be open for inspection to members and their guests.

TECHNICAL SESSIONS

The first two technical sessions are on selected subjects; the third will present a symposium on noise, and the fourth session, a symposium on lightning. The selected subjects offer a variety of papers, some on cables, others on special transformers, cusps in the speed-torque curves of induction motors, and equivalent circuits of imperfect condensers.

JOINT SESSION ON NOISE ABATEMENT

With the object of outlining a broad and efficacious program on "noise investigation" and in worthy conclusion of the morning session at which will be presented a symposium on "Noise in Electrical Machinery," a joint meeting will be held on the evening of April 30, 1931, at which the N. E. L. A., N. E. M. A., A. S. M. E. and A. I. E. E. will all be capably represented. The morning symposium will include methods of noise reduction, described by Westinghouse engineers, the manufacturers' view of the noise problem summarized by Prof. B. F. Bailey, University of Michigan, chairman of N. E. M. A. committee on noise, and a paper by E. A. Bishop of the Commonwealth Edison Company, Chicago, on the mitigation of noise in substations.

ENTERTAINMENT

An informal reception, with dancing and card playing will be held on Wednesday evening. The following evening will be devoted to an inspection of the Eastman Theater and Eastman School of Music. The theater is reputed to be one of the most beautiful in the country, and the School of Music, in the short time it has been operating, has achieved international distinction. The theater will offer a performance of current attraction.

THE MEETING DINNER

A dinner will be held on Friday evening, when H. H. Sullivan, past-president of the Rochester Engineering Society, will act as toastmaster, and Professor Walter King Stone of the College of Architecture, Cornell University, will give an address on "What the Artist May Contribute." Entertainment and dancing will follow the presentation of district prizes.

LADIES' ENTERTAINMENT

In addition to the foregoing entertainment, the Ladies' Committee has arranged a special program of luncheons, a luncheon and bridge at the home of Mrs. H. H. Sullivan, and sightseeing trips to some of Rochester's most scenic points.

LADIES' PROGRAM

WEDNESDAY, APRIL 29

9:00 a. m. Registration at meeting headquarters
12:30 p. m. Luncheon at Sagamore Hotel
2:00 p. m. Sightseeing trip
8:00 p. m. Reception at Sagamore Hotel

THURSDAY, APRIL 30

Morning free for shopping
1:00 p. m. Luncheon and bridge at the home of Mrs. H. H. Sullivan
7:30 p. m. Inspection of Eastman Theater and Eastman School of Music, including a performance of current attraction

FRIDAY, MAY 1

12:00 m. Luncheon
2:00 p. m. Sightseeing trip
7:00 p. m. Dinner

INSPECTION TRIPS

A program of interesting and profitable inspection trips to large and well-known manufacturing plants in Rochester also to the utility interests and the University of Rochester has been scheduled for Thursday afternoon and Saturday morning. In addition, several inspection trips for the students have been arranged for Friday afternoon at 2:00 p. m.

HOTEL RESERVATIONS

Reservations at the various hotels are available by writing to O. L. Angevine, executive secretary of the Rochester Engineering Society, 111 East Avenue, Rochester, N. Y. A form for this purpose will be mailed with announcement to the membership; also a list of the rates for the various hotels.

COMMITTEES

The personnel of the district meeting committee consists of: I. E. Moultrop, vice-president, North Eastern District, chairman; A. C. Stevens, secretary-treasurer, North Eastern District; J. N. Alberti; C. W. Henderson; E. C. Karker; C. H. Kline; H. J. Klumb (chairman of the local executive committee); R. G. Warner; and F. C. Young. The officers of the general committee are: E. C. Karker, chairman; F. C. Young, secretary-treasurer; H. S. Collins, assistant secretary-treasurer. The following are chairmen of the various subcommittees: O. L. Angevine, hotels and registration; V. M. Graham, inspection trips and transportation; O. L. Angevine, publicity; J. G. Carritt, entertainment and banquet; W. H. Reichard, sports; H. J. Klumb, finance; Mrs. O. L. Angevine, ladies' entertainment.

Tentative Program

(Eastern Standard Time)

Wednesday, April 29

9:00 a. m. Registration
10:00 a. m. Welcoming addresses:

Stephen B. Story, City Manager

Virgil M. Palmer, Rochester Engineering Society

10:20 a. m. Session on Selected Subjects

TEMPERATURES IN ELECTRIC POWER CABLES UNDER VARIABLE LOADING, E. A. Church, Edison Electric Illuminating Company of Boston.

PROXIMITY EFFECT IN CABLE SHEATHS, H. B. Dwight, Massachusetts Institute of Technology

CUSPS IN THE SPEED-TORQUE CURVES OF INDUCTION MOTOR DUE TO SPACE HARMONICS, P. H. Trickey, Westinghouse Electric & Mfg. Co.

LOSSES IN TRANSFORMERS FOR USE WITH MERCURY ARC RECTIFIERS, E. V. DeBlieux, General Electric Co.

2:00 p. m. Session on Selected Subjects

Theory of Thermal Breakdown of Solid Dielectrics, P. H. Moon, Massachusetts Institute of Technology

The Three-Circuit Transformer, C. F. Estwick, General Railway Signal Co.

Core-Loss Measurements at High-Flux Density, B. M. Smith and C. Concordia, General Electric Co.

Equivalent Circuits of Imperfect Condensers, C. L. Dawes and W. M. Goodhue, Harvard University

8:00 p. m. Informal reception—dancing and cards

Thursday, April 30

9:00 a. m. Symposium on Noise

The Measurement of Noise in Electrical Machinery, B. F. Bailey, University of Michigan

An Indicating Meter for the Measurement and Analysis of Noise, T. G. Castner, Bell Telephone Laboratories, E. Dietze and R. S. Tucker, American Telephone and Telegraph Co., and G. T. Stanton, Electrical Research Products, Inc.

The Measurement of Machinery Noise, H. B. Marvin, General Electric Co.

Induction Regulator Noise, J. P. Foltz and W. B. Shirk, Westinghouse Electric & Mfg. Co.

Magnetic Noise in Synchronous Machines, Q. Graham, P. Milliken, and S. Beckwith, Westinghouse Electric & Mfg. Co.

Elastic Supports for Isolating Rotating Machinery, E. H. Hull and W. C. Stewart, General Electric Co.

Noise Mitigation in Substations, E. A. Bishop, Commonwealth Edison Co.

12:00 m. District Executive Committee luncheon

2:00 p. m. Inspection trips:

Bausch and Lomb Optical Company
Stromberg-Carlson Telephone Mfg. Co.
Monroe Telephone Exchange
Kodak Park Works, Eastman Kodak Co.

2:00 p. m. Symposium on Noise—*continued*

Demonstration of Noise Measurement Apparatus

6:15 p. m. Joint Dinner Meeting of representatives of National Noise Study Committees of N.E.L.A., N.E.M.A., A.S.M.E., A.I.E.E. and other organization

7:30 p. m. Inspection of Eastman Theater and Eastman School of Music, including a performance

Friday, May 1

9:00 a. m. Student technical session

12:00 m. Student luncheon

2:00 p. m. Student inspection trips:

University of Rochester
Eastman Kodak Co.
Station 33, Rochester Gas & Electric Corp.

2:00 p. m. Symposium on Lightning

Lightning, F. W. Peek, Jr., General Electric Co.

Lightning Discharges and Line Protective Measures, R. N. Conwell, Public Service Electric & Gas Co., and C. L. Fortescue, Westinghouse Electric & Mfg. Co.

Lightning Investigation on the 220-Kv. System of the Pennsylvania Power and Light Co., Edgar Bell and A. L. Price, Pennsylvania Power and Light Co.

1930 Lightning Investigations on the Transmission System of the American Gas and Electric Company, Philip Sporn, American Gas and Electric Co., and W. L. Lloyd, Jr., General Electric Co.

Lightning Investigation on the Appalachian Electric Power Company's Transmission System, I. W. Gross, American Gas and Electric Co., and J. H. Cox, Westinghouse Electric & Mfg. Co.

Experimental Studies in the Propagation of Lightning Surges on Transmission Lines, O. Brune and J. R. Eaton, Consumers Power Co.

Lightning Investigation on Transmission Lines—II, W. W. Lewis and C. M. Foust, General Electric Co.

6:30 p. m. Dinner; lecture, presentation of district prizes, and entertainment with dancing.

Saturday, May 2

8:30 a. m. Symposium on Lightning—*continued*

9:00 a. m. Inspection trips:

General Railway Signal Company
Station 9 of Rochester Gas and Electric Corp.
Coke Plant of Rochester Gas and Electric Corp.
University of Rochester
Niagara Falls

1931 Year-Book Now Available

The Institute's year-book for 1931, containing as usual a complete listing arranged both alphabetically and geographically of names and addresses of all members (correct to January 1, 1931), a copy of the by-laws and constitution, list of Institute officers and committees, as well as other information of interest in Institute activities, is now available for distribution.

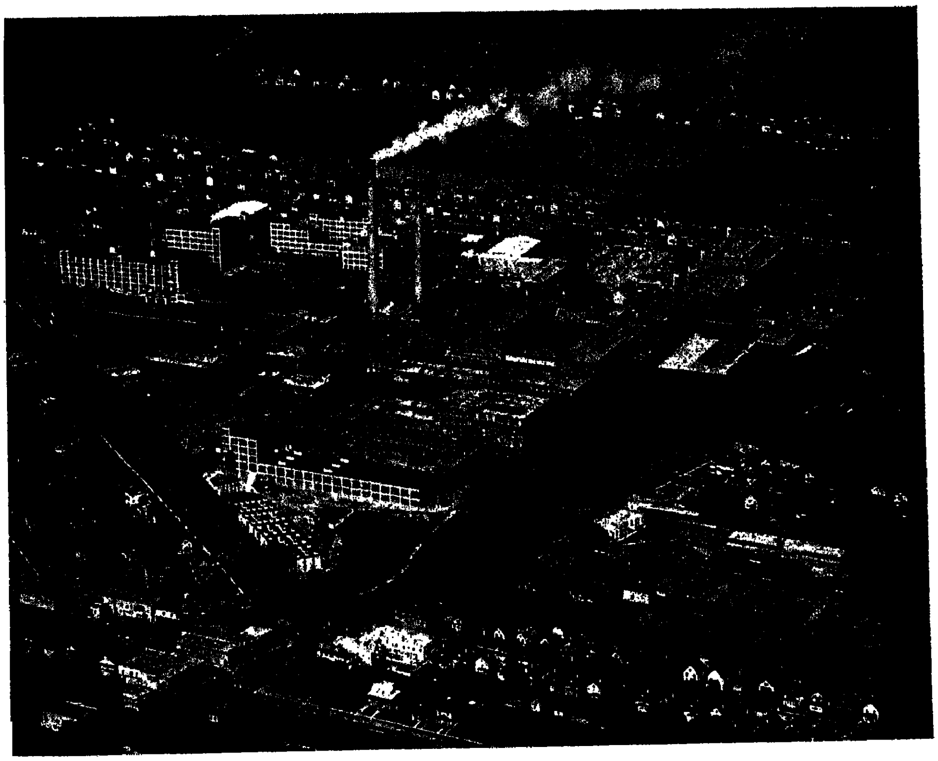
On page 127 there will be found a paragraph requesting the earnest cooperation of all members to prevent the use of this year-book for advertising or circularizing purposes. Any such action must be considered as outside of its field of application, and as absolutely prohibited.

◆

Chemical Exposition To be Held in New York

The thirteenth exposition of Chemical Industries will be held at the Grand Central Palace, New York, during the week May 4-9, 1931.

The biennial exposition regularly includes not only exhibits from all of the forty or more industries classified as chemical, but also those from many others producing material or equipment used in chemical industries. Thus is offered an opportunity for studying a large array of equipment, and for comparing competitive products side by side.



Kodak Park—headquarters of the Eastman Kodak Co., one of Rochester's many nationally known industries

Plan Your Vacation to Include the Lake Tahoe Convention

AN OPPORTUNITY for a delightful and useful summer trip is afforded by the choice of Lake Tahoe, California, as the scene of the Pacific Coast convention to be held August 25-29, 1931. Lake Tahoe is strategically situated—on a transcontinental main-line railroad, a mile high in the famous Sierra Nevada Mountains—and provides facilities that will make this a highly successful family convention. And the high-caliber technical program that rapidly is being completed will well justify an extra effort to attend.

◆

All Engineers Welcome At International Congress, England

Anyone expecting to attend the 1931 International Illumination Congress opening at London September 2, 1931 (detail of which was published in the January Electrical Engineering, p. 59), should notify G. H. Stickney, secretary of the U. S. National Committee, Nela Park, Cleveland, Ohio.

Every endeavor is being made to keep the cost of travel as reasonable as possible; the conference is open to all interested in illumination in any of its branches, and the registration fee of £2 includes a copy of the proceedings of the congress; ladies exempt from all fees. A reception will be tendered by the civic authorities of each city in which the congress holds session.

◆

A. S. A. Releases Refrigeration Safety Code

The American Standards Safety Code for Mechanical Refrigeration has just been published (February 1931) by the American Standards Association, 29 West 39th Street, New York, N. Y. The code which is sponsored by the American Society of Refrigerating Engineers, was approved by the American Standards Association in October 1930, and already has been adopted in its entirety by several cities; still others are considering its adoption. It represents one of the most important instances of the precaution necessary to prevent improper installation or use of technical equipment, already being taken by industry instead of its waiting to be forced into such action by public demand.

The booklet containing the safety code contains complete but concise information about the code and its advantages. It has been prepared as a reference manual for the use of any person or organization interested in its general adoption and use and it provides thoroughly practical and adequate regulatory measures for safe installation, operation, and inspection of mechanical refrigeration systems or units.

◆

Washington Award Made to Ralph Modjeska

On February 25, 1931, before 360 members and guests of the five societies participating, Doctor Ralph Modjeska who in 1929 received the John Fritz Medal, highest American engineering award, had bestowed upon him the new honor of the Washington Award "for pre-eminent service in advancing human progress." Dr. Modjeska's history is too well known to require delineation here.

This award is administered by the Western Society of Engineers (Chicago) upon the recommendation of a commission representing the four founder societies; this year's ceremonies were at the Palmer House, Chicago, with Elmer T. Howson, chairman of the commission, presiding. Dr. Modjeska's acceptance was brief and was followed by a well-planned program at which Ralph Budd, president of the Great Northern Railway and principal speaker of the evening, gave an inspiring address upon the importance of the engineer's qualifying more fully to meet the economic problems bearing upon human progress.

Summer Convention At Asheville, N. C., June 22-26

The annual summer convention of the Institute will be held at Asheville, N. C., June 22-26, with headquarters at the Grove Park Inn.

Asheville, widely proclaimed by President Lee as the "land of the sky," is located in the highest part of the Blue Ridge Mountains, at an elevation of approximately 2,700 ft., and is counted one of the most scenic splendors of the South. Mt. Mitchell, rising to a height of 6,711 ft., and the highest peak east of the Rockies, is but a short distance away. The city's geographical location offers a splendid opportunity for members and their guests to visit such scenic points as Chimney Rock, Lake Lure, etc.

Seven technical sessions of broad scope and current interest have been scheduled tentatively as follows: automatic stations, symposium on system interconnection, cables, communication, instruments and measurements, electrical machinery, selected subjects, and research. The annual reports of technical committees, outlining advances in theory and practise of electrical activities in the various fields will also become available.

More complete details of this exceptional program will be announced in subsequent issues of Electrical Engineering.

◆

Two Important Meetings at Birmingham

Birmingham (Ala.) the "largest city for its age in the world" will be possessed of a double importance when The American Society of Mechanical Engineers holds its semi-annual meeting there April 20-23, 1931, followed by an overlapping meeting of the American Electrochemical Society April 23-25. Headquarters for both of these meetings will be the Hotel Tutwiler, ideally situated in the "city beautiful" which lies among the foothills of the Appalachian Mountain group, with Red Mountain, Shades Mountain, the Mountain Brook Country Club, and the Birmingham Country Club all close at hand.

A system of electrification has been built up covering the state from Muscle Shoals to Mobile; a part of the attractive program arranged for the A. S. M. E. meeting will be devoted to the inspection of important industrial plants with generous allowance of time to be spent on hydroelectric installations—the Alabama Power Company's installation at Martin Dam, a reservoir of 40,000 acres furnishing 3,000,000 kw. storage, and Jordan Dam, the maximum head of which is 91 ft. Also there will be an interesting railroad session, one on power, another on safety, and still another on the handling of materials and machine shop practise, besides others devoted to subjects of more purely mechanical interests, each however with its quota of well-selected and carefully prepared subjects.

◆

Astronomy and Electricity

As a fitting climax to one of the most successful years that the New York Section of the Institute has ever had, where the total attendance will exceed by 350 per cent that of the previous year, the officers of the Section have arranged an evening on "Astronomy and Electricity" to be held jointly with the New York Electrical Society in the Engineering Auditorium, 33 West 39th Street, New York, at 8:15 p. m. on Friday, April 24, 1931.

The speaker will be Dr. H. T. Stetson, director of the Perkins Observatory of Ohio Wesleyan University, Delaware, Ohio, which has the third largest telescope in the world. Dr. Stetson will outline clearly the results of recent investigation of the effects of solar activity on the earth's magnetism and on radio transmission. Sun spots and other astronomical phenomena will be dealt with in a manner understandable and entertaining to the engineer.

Preceding Dr. Stetson's talk, a description of the "Electrical Projection Planetarium" will be presented by Dr. Clyde Fisher of the American Museum of Natural History.

Both speakers are eminent in their respective fields and both talks will be profusely illustrated.

Annual Report Issued by United Engineering Trustees, Inc.

In calling attention to the availability of the annual report of United Engineering Trustees, Inc., a short historical outline may be of interest.

The United Engineering Trustees, Inc., which originally was called the United Engineering Society and then for a time Engineering Foundation, Inc., was incorporated in 1904 to administer the Engineering Societies Building, certain endowments, and other funds for its Founder Societies, the national societies of civil, mining, mechanical, and electrical engineers. Its objects—which are to maintain a free engineering library—to advance the engineering arts and sciences, to further research, are carried on through its three departments: The Engineering Societies Library, The Engineering Foundation, and the Administrative Department.

The three events of greatest significance in its history are the erection of the Engineering Societies Building at 29 West 39th Street, New York City (dedicated in 1907), the consolidation of the various society libraries in 1913 together with the establishment of the Library Endowment Fund by a gift from Dr. James Douglas of $100,000, and the creation of an engineering research foundation known as The Engineering Foundation, through the suggestion and generosity of Ambrose Swasey, whose gifts now total half a million dollars. The various funds over which the trustees now have supervision amount to $1,136,000.

In President Francis Lee Stuart's annual report for 1930 it is pointed out that the assets for which the corporation is responsible (real estate at cost, funds, and library as appraised) total $3,524,422.27. The development committee gathered data during the year on which to base an

SUMMARY OF 1930 FINANCIAL REPORT

Operation of Building		
Credit balance January 1, 1930		$12,290.66
Building revenue 1930	$133,170.65	
Building expenditures 1930	120,274.58	12,896.07
Total		$25,186.73
Annual payment to dep. and renewal fund	$12,000.00	
Reimbursement of general reserve fund	1,000.00	
Payment to reserve for future fire insurance	1,550.00	14,550.00
Credit balance December 31, 1930		$10,636.73
Operation of Library		
Maintenance revenue	$50,287.71	
Maintenance expenditures	48,046.69	
Credit balance for year 1930	2,241.02	
Credit balance from preceding years	3,447.93	
Total credit balance December 31, 1930		$ 5,688.95
Service bureau revenue	$21,559.89	
Service bureau expenditures and adjustments	20,842.18	
Credit balance for year 1930	717.71	
Credit balance from preceding years	4,016.25	
Total credit balance December 31, 1930		$ 4,733.96
Funds and Property		
Funds held by U. E. T. Inc., Dec. 31, 1930 (Book Value)		
Depreciation and renewal fund		283,734.79
General reserve fund		3,934.40
Engineering foundation fund		529,253.65
Henry R. Towne engineering fund		50,078.13
Library endowment fund		173,475.32
Edward Dean Adams fund		100,000.00
John Fritz Medal fund (Custodian)		3,500.00
Louvain Memorial fund		8,589.95
Total		$1,152,566.24
Real estate owned, cost to Dec. 31, 1930		1,987,793.92
Operating cash and petty cash		15,592.43
Accounts receivable		1,878.79
Value of library (as appraised for insurance)		358,544.00
Endowment committee loan receivable		1,700.00
Unexpired fire insurance premiums		3,297.09
Fire insurance fund (cash uninvested)		3,050.00
Total property which U. E. T. Inc. owns or holds		$3,524,422.47

estimate of the societies' needs for accommodations in the next ten years or more and a project for meeting those needs is under consideration. The Engineering Societies Building is reported in good condition but overcrowded.

In April, 1930 at the 50th anniversary of the American Society of Mechanical Engineers, a memorial tablet was placed in the entrance hall. The War Memorial to American Engineers in the Louvain Library continues to be of great interest to visitors to Belgium.

In passing to the summary of the financial report, it is worthy of note that all departments closed the year without deficits.

Engineering Foundation

Dielectric Research to Reveal Fundamental Properties

A study of the fundamental properties of dielectrics, a research conducted by Prof. J. B. Whitehead at The Johns Hopkins University, Baltimore, is part of a comprehensive program directed by the National Research Council's committee on electrical insulation.

During the year, the work on the research aided by Engineering Foundation has been mostly the design, construction, and installation of apparatus for exhaustive investigation of the dielectric properties of liquids, particularly insulating oils. The apparatus was successfully completed during 1930 and papers covering these researches are appearing from time to time in the publications of the A. I. E. E.

◆

Welding Research Aided by Foundation

At the request of the A. I. E. E. the Engineering Foundation is aiding an investigation of pure iron electrodes to obtain basic data of use to electric welders.

This research is being conducted by Prof. Gilbert E. Doan under an agreement between the Foundation and Lehigh University. It was undertaken in June 1930 and progress has been made in designing and installing special apparatus and in developing methods.

Standards

Specifications for Dry Cells and Batteries

American standard specifications for dry cells and batteries have been issued recently as Circular No. 390 of the Bureau of Standards. These specifications prepared by the Bureau with the cooperation of manufacturers and users are a revision of the American standard of Feb. 27, 1928. The revision has been carried out concurrently by a technical committee of the Federal Specifications Board and the sectional committee of the A. S. A.; the two specifications are identical in substance, differing only in arrangement. Copies of Circular No. 390 may be obtained from the Superintendent of Documents, Washington, D. C., at a price of 5 cents per copy.

◆

Weatherproof and Heat-Resisting Wire and Cable Specifications Approved

Two specifications developed by the sectional committee on insulated wires and cables came before the standards committee of the Institute on January 23, when they were approved by it; and subsequently by the board of directors on January 28, 1931. The specifications are as follows:

1. Weatherproof (weather-resisting) Wires and Cables: These specifications cover weatherproof wires and cables and the materials used for the braids and saturating compounds as applied to metallic conductors.

2. Heat-Resisting Wires and Cables: These cover the usual type of heat-resisting coating commonly known as "slow-burning," applied to metallic conductors for use in hot, dry locations where the standard insulating materials would not endure long or where the presence of large masses of inflammable materials would be objectionable.

Both of these specifications were developed by the committee acting under the procedure of the American Standards Association and the sponsorship of the A. I. E. E. and nine other bodies. They are now before A. S. A. for approval as American standards and upon the granting of such approval will be issued in pamphlet form by the Institute.

Specifications for Code Rubber Approved

A "Specification for Code Rubber Insulation for Wire and Cable for General Purposes" as developed by the sectional committee on insulated wires and cables, also was approved by the standards committee and subsequently (Jan. 28, 1931) by the board of directors. This specification will follow the same procedure as the two previously mentioned, and upon approval as an American standard will be issued by the Institute.

◆

Revised Report on Proposed Lightning Arrester Standards

The protective devices committee of the Institute has just reported on revision of the proposed "Standards for Lightning Arresters." The first report on this subject has been available since May 1928; the revision will be issued in pamphlet form replacing Report No. 28 of that date. Comments and criticisms are urgently requested and should be forwarded to Raymond Bailey, chairman A. I. E. E. protective devices committee, Philadelphia Electric Co., 900 Sansom St., Philadelphia, Pa. Copies of revised Report No. 28 may be had without charge by addressing H. E. Farrer, secretary standards committee, A. I. E. E., 33 West 39th St., New York, N. Y.

Personal

D. C. PRINCE has been appointed engineer of the switchgear department of the General Electric Company at Philadelphia. The appointment includes supervision of switchgear research activities at Schenectady. Mr. Prince has been with the General Electric since 1912, his work including the radio engineering department, the research laboratory and the switchgear department as research engineer. R. M. Spurck continues as assistant engineer with extended duties, and Chester Lichtenberg, assistant engineer since 1927, has been relieved of his duties to undertake a special assignment.

◆

E. O. SHREVE, assistant vice-president in charge of sales, General Electric Company, Schenectady, made a tour of its western offices last month, including those in Dallas, Houston, El Paso, Phoenix, Los Angeles, San Francisco, Portland, Seattle, Spokane, Salt Lake, and Denver. In his capacity as a director in the American Management Association, he spoke before the Iron and Steel Conference, California State Chamber of Commerce, at Del Monte, Calif., and was the feature speaker at a meeting of the San Francisco Electrical Development League.

◆

Hadley F. Freeman of Cleveland associating himself with G. M. Albrecht, former examiner in the United States Patent Office has opened offices under the company name of Freeman and Albrecht, Patent Attorneys, at 807 Mariner Tower, Milwaukee, Wisconsin. Mr. Freeman is a member of the firm of Smith and Freeman, Patent Attorneys, Cleveland, and of Freeman and Sweet, Patent Attorneys, Chicago; both will be represented by the new firm.

◆

H. C. Leonard, who was elected president of the Electrical League of El Paso (Texas) at a recent meeting, has been known to the electrical fraternity of El Paso for less than a year. He came to the western city last summer to take over the duties of general superintendent of the El Paso Electric Company, succeeding W. R. Bell, who was transferred to other Stone & Webster properties at Baton Rouge, La.

◆

Frank J. Airey, division manager of the General Electric Supply Corporation at Los Angeles, was elected chairman of the Pacific Division, National Electric Wholesalers' Association, at the annual meeting of the organization at Del Monte, Calif. He has been in the electrical merchandizing business more than 42 years, having occupied the various positions of salesman, sales manager, division manager and general manager.

◆

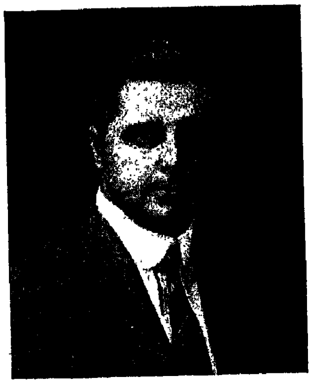
W. H. Lesser has been appointed combustion and mechanical engineer of the newly organized Penn Anthracite Collieries Company, Scranton, Pa. Mr. Lesser has wide practical experience in the preparation, utilization, and distribution of anthracite. As a member of the American Institute of Electrical Engineers he has served as chairman of the Committee on Applications to Mining Work.

D. W. Proebstel, for many years test engineer for the Portland General Electric Company, Portland, Ore., and its predecessors, has been promoted to the engineering department of the parent company, Central Public Service Corporation, Chicago. In his new position Mr. Proebstel will be assistant in electrical engineering to L. N. Boysen, who is assistant to the operating vice-president.

◆

J. B. MacNeill Now Distribution Manager

J. B. MacNeill, who has held successively the positions of circuit-breaker engineer, section leader on circuit breakers, and manager of the circuit-breaker engineering department of Westinghouse Electric and Manufacturing Company, has now received a new appointment as general manager of distribution engineering with headquarters at East Pittsburgh. This group comprises the engineering activities of switchboards, circuit breakers, meters, relays, high-voltage insulators, and lightning arresters. Improvements in modern switching equipment including the development of deion circuit breakers has been carried out under Mr. MacNeill's direction. He is a member of the National Electrical Manufacturers Association, and spent the summer of 1930 reviewing European practise on switchgear and distribution apparatus, after attending the World Power Conference at Berlin as a representative of NEMA.



J. B. MacNeill

◆

Albert M. Jacobs has been elected president of the South African Institute of Electrical Engineers for the current year. For the past five years he has been a member of the board and chief technical offices of the Electricity Supply Commission in the Union of South Africa.

Charles F. Ruffner has resigned as a vice-president of the Niagara-Hudson Power Company, but continues as chairman of the board and a director of the New York Power & Light Corporation.

◆

Thomas S. Wood, electrical manufacturers' agent, Seattle, recently attended the annual convention of the Sangamo Electric Company at Springfield, Ill.

◆

S. R. Inch, a vice-president of the Electric Bond & Share Company, has been elected executive vice-president.

◆

T. S. Perkins Named Merchandising Manager

T. S. Perkins has been chosen to head the new "merchandising department" of Westinghouse Electric and Manufacturing Company, East Pittsburgh, and will become executive of these new engineering activities with the title of general manager of merchandising engineering. In this position he will represent S. M. Kintner, assistant vice-president, in work of supply, appliance, refrigeration, and illuminating engineering departments. Mr. Perkins joined the Westinghouse organization immediately after his graduation from Worcester Polytechnic Institute in 1893 and has been with that company continuously since that time. For six years he has been a member of the Irwin (Pa.) Borough Council and president of that body for two years. He also has served as vice-president of the Westmoreland County Council, Boy Scouts of America; he was one of the organizers of the Irwin Saving and Trust Company, of which he is one of the directors, and is a past-president of the Irwin Chamber of Commerce.

T. S. Perkins

Obituary

A. H. Crossman, sales engineer for the Pacific Electric Mfg. Corp., San Francisco, California, and an Associate of the Institute since 1928, died at his home, Burlingame, Calif., February 8, 1931. A native of Cambridge, Mass., Mr. Crossman obtained his A. B. from Bowdoin College, Brunswick, Maine, in 1916 and his B. S. degree from M. I. T. in 1923, specializing in Economics at the first mentioned college and in hydroelectric engineering at M. I. T. In three years, from 1917 to 1920, he rose from second lieutenant to captain's rank in the Coast Artillery Corps, U. S. Army; three years later he joined the Southern Sierra Power Company at Riverside, Calif., embracing a student course which it was offering and advancing from Engineer in the distribution department to sales engineer, his last office.

◆

H. M. Walmsley, a Member of the Institute since 1921, died January 5 at Christ Hospital, Cincinnati, Ohio, following an operation for appendicitis. He had been in the electrical engineering field ever since 1905, when he took the G. E. Test Course at Schenectady immediately following graduation from Purdue University. He was born in Chicago, and his first work after completion of the Test Course was with the operating and construction departments of the Commonwealth Edison Company. From Chicago he went to Canton, Ohio, as resident engineer for Sargent and Lundy and the American Gas and Electric Company and also the Canton Electric Company. In the interests of the first two companies, he went to West Virginia to care for the erection of a new 10,000-kw. station for the Wheeling Electric Company. This was in 1913, and the following year he represented these same firms in the work of a new power station for the Ohio Light and Power Company, at Newark, Ohio. A $7,000,000 station and distribution system for the Cincinnati Gas and Electric Company was another product of his executive ability, as were the stations of the Kansas City Light and Power Company, the Public Service Company of Oklahoma, and the power and ice-plant of the Albilene Light, Water and Gas Company, Albilene, Texas. Mr. Walmsley was a member also of the American Society of Mechanical Engineers.

◆

Harry J. Hunsicker, electrical engineer of the New York Power and Light Corporation, Albany, died suddenly March 6th of acute dilation of the heart. He was born at Lehighton, Pa. July 5, 1879, and since 1907 had been an Associate of the Institute. His B. S. in E. E. was conferred upon him when he graduated from the Pennsylvania State College in 1901, and in July of that same year he entered the testing department of the General Electric Company at Schenectady. In August 1903 he joined the Hudson River Electric Power Company, first on electrical construction work, but rising shortly to the office of assistant electrical engineer. Mr. Hunsicker was active in building the Spier Falls hydraulic project, one of the important developments of the section in which he has spent most of his professional life.

◆

V. O. Chewning, assistant electrical engineer of the Illinois Terminal Railroad System, died February 15, 1931, in the Barnes Hospital, St. Louis, Mo. Mr. Chewning was born at Taylorville, Ill., in 1892; he served two years overseas during the World War and for three years was employed as local manager for the Central Illinois Public Service Company at Charleston, Illinois. Ten years ago he joined the Illinois Terminal Railway System, where his services were principally on the construction, maintenance and operation of railway substations. For a year and a half he was chief power dispatcher for the company at Taylorville, Illinois. He joined the Institute as an Associate in 1922.

Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the addresses as they now appear on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Davis, R. H., Westinghouse E. & M. Co., East Pittsburgh, Pa.

Dawson, Leonard L., 98 Looker Ave., Springfield, N. J.

DiLucci, A., Box 1051, Chicago, Ill.

Duane, George B., Otis Elevator Co., Yonkers, N. Y.

Gale, R. E., 706 N. 19th St., Boise, Idaho.

Kigar, D. F., 1403 Minnie St., Port Huron, Mich.

Muncy, V. E., Ohio Mechanics Institute, Cincinnati, Ohio.

Nichols, F. A., 301 Belmont Apts., Seattle, Wash.

Prehn, Victor N., 940 Broad St., Newark, N. J.

Sherwood, W. E., Kew Gardens, 2700 Que St. N. W., Washington, D. C.

Sliney, David, 11 Orchard St., Cranford, N. J.

Van Wyck, P. V. R., Summit, N. J.

Local Meetings

Joint Meeting Held in Virginia

A joint meeting of the local Sections of the A. S. C. E., A. S. M. E., and A. I. E. E. and the Engineers Club of Hampton Roads was held at the Southland Hotel, Norfolk, January 30-31, 1931, with an attendance of 94. The program was as follows:

Friday Morning

F. F. Harrington, chairman, Virginia State Section, A. S. C. E., presiding.

Industrial Heating, by M. K. Clark, York Heating and Ventilating Corp.

The Fair of the Iron Horse—A moving picture. Business sessions of State Sections.

Luncheon

Charles W. Johnston, president, Engineers Club of Hampton Roads, presiding.

Welcoming Address, by Hon. E. Jeff Robertson, Mayor of Norfolk.

The North Atlantic Ice Patrol, by Captain William J. Wheeler, U. S. Coast Guard, with moving picture film.

Weather Predicting, by C. H. Richardson, meteorologist, U. S. Weather Bureau, Norfolk, Va.

Friday Afternoon

Motor bus excursion to Little Creek Terminal, Penn. R. R.; Cape Henry, Va.; Fort Story, (harbor defenses of Chesapeake Bay); and Virginia Beach.

Friday Evening

Dinner at Pine Tree Inn, Virginia Beach, J. H. Berry, chairman, Southern Virginia Section, A. I. E. E. presiding.

Technological Unemployment, by Professor Dexter S. Kimball, dean of the College of Engineering, Cornell University.

Electricity—Past, Present, and Future, by C. M. Ripley, General Electric Co.

Saturday

Golf; special visits to Navy Yard, Naval Base, and other places of interest.

At the business meeting of the A. I. E. E. Section the following officers were elected to take office February 1, 1931: J. H. Berry, Chairman; E. L. Lockwood, Secretary-Treasurer; E. S. Fitz and S. C. Foster, Executive Committee.

◆

Branches Organized at U. of Illinois and Rice Institute

The formation of Student Branches of the Institute at the University of Illinois and at Rice Institute was authorized by the Board of Directors at its meeting held on January 28, 1931. Both groups have completed their organization, and the following officers are in charge:

University of Illinois: W. P. Burgland, president; F. M. Deerhake, vice-president; G. L. Bodwell, secretary; R. R. Wood, treasurer.

Rice Institute: A. R. Edwards, president; D. B. Good, vice-president; M. E. Kattmann, secretary; K. Beyette, treasurer; A. M. Wittmann, executive committee member.

Future Section Meetings

Cleveland

April 16, 1931—Human Relations in Industry, by Whiting Williams. Joint meeting with Student Branch of Case School of Applied Science, at which two papers will be presented by students.

May 21, 1931—Annual dinner meeting. Speaker—W. S. Lee, vice-president and consulting engineer, Duke Power Company, and president, American Institute of Electrical Engineers.

Detroit-Ann Arbor

April 21, 1931—1000-Deg. Turbine, by Paul W. Thompson, Detroit Edison Co. Meeting to be held at the Detroit Edison Auditorium.

May 19, 1931—Subject and speaker to be announced later.

Lehigh Valley

April 24, 1931—Ladies' Night, to be held at Americus Hotel, Allentown, Pa.

May 16, 1931—Annual Meeting. System Development, by E. C. Stone, assistant to senior vice-president, The Philadelphia Company. Meeting to be held at Altamont Hotel, Hazleton, Pa.

Niagara Frontier

April 17, 1931—Art of Engineering, by Mr. Dohner, Westinghouse Electric & Mfg. Co.

May 15, 1931—Subject and speaker to be announced later.

Seattle

April 21, 1931—Annual joint meeting with the A. I. E. E. Student Branch of the University of Washington. Program under the auspices of the students.

May 19, 1931—The best paper submitted in the annual competition for prizes will be presented at this meeting.

Sharon

May 5, 1931—The Contributions of Telephone Research to the Talking Motion Picture Industry, by J. O. Perrine, Associate Editor, *Bell System Technical Journal.*

Spokane

April 24, 1931—Joint meeting with the Student Branches of The State College of Washington and University of Idaho. Papers by local members and students. Meeting to be held at Pullman, Wash.

May 22, 1931—Annual Dinner Meeting. History of the Electrical Development of the Inland Empire, by John B. Fisken. Election of officers.

Toledo

April 17, 1931—High Lights in the Glass Industry, by A. H. Stebbins, Libbey Ford Glass Co. Storage Batteries, by W. E. Dunn, Electric Storage Battery Co.

May 22, 1931—Speakers—T. J. Nolan, Toledo Edison Co. and J. T. Greene, Police and Fire Alarm System.

Past Section Meetings

Akron

Electronic Tubes and Their Applications, by H. P. Sparkes, Westinghouse Electric & Mfg. Co. Demonstrations. February 12. Attendance 150.

Atlanta

Speed, Unemployment and Progress, by Dr. William McClellan, vice-president, Stone & Webster Engineering Corp. Dinner preceded the meeting. February 27. Attendance 73.

Baltimore

Marvels of Sound Transmission, by S. P. Grace, assistant vice-president, Bell Telephone Laboratories, Inc. Demonstrations. Meeting held jointly with all engineering societies of Baltimore and the Association of Commerce. Dinner in honor of the speaker preceded the meeting. January 16. Attendance 1,700.

Municipal Rapid Transit Subways of New York City, by Robert Ridgway, chief engineer, Board of Transportation of New York City. Illustrated. Joint meeting of the local engineering societies, sponsored by the A. S. C. E. February 4. Attendance 120.

The proposed bill for the Registration of Engineers in the State of Maryland was discussed by the following speakers: Henry G. Perring, S. S. Steinberg, W. B. D. Penniman, W. B. Kouwenhoven F. T. Leilich, E. D. Edmonston, A. L. Penniman, and others. After considerable discussion a resolution was unanimously adopted stating that the enactment of the registration law in the Maryland Free State was neither desirable nor beneficial to either the public or the members of the engineering profession. February 17. Attendance 200.

Lightning Research, by Edward W. Beck, Westinghouse Electric & Mfg. Co. Mr. Beck presented a résumé of the lightning researches carried out in Tennessee and New Jersey, and showed numerous slides illustrating experiments with the auto-valve arrester that have been performed on transmission lines. February 20. Attendance 78.

Cincinnati

Television: Its Physical, Psychological, and Fundamental Principles, by Dr. J. O. Perrine, associate editor, *Bell System Technical Journal.* Demonstration of the use of the scanning disk and photoelectric cell. January 15. Attendance 570.

Some New and Interesting Developments in Engineering and Research, by A. M. Dudley, Westinghouse Electric & Mfg. Co. February 12. Attendance 98.

Cleveland

The Flying Telephone, by F. M. Ryan, Bell Telephone Laboratories, Inc. The development work which was necessary before actually designing telephone equipment for aeronautical purposes was explained and illustrated. February 19. Attendance 176.

Columbus

Recent Advances in Aircraft Communication, by F. M. Ryan, Bell Telephone Laboratories, Inc. Illustrated by lantern slides and a Western Electric sound picture "The Flying Telephone;" also, an exhibition of the types of apparatus employed in aviation radio installations. February 20. Attendance 135.

Connecticut

Glass Insulation, by Wm. W. Shaver, Corning Glass Works. Slides and moving pictures were presented illustrating the manufacture of glass, methods of handling and moulding glass, and the comparative tests of glass insulators with porcelain insulators. February 11. Attendance 63.

Dallas

St. Louis-Dallas Underground Toll Cable, by C. W. Nystrom, Southwestern Bell Telephone Co. Illustrated with films and slides. January 19. Attendance 106.

Lighting the Home, by Miss Ethel Hudson, Dallas Power & Light Co. Illustrated with slides. Joint meeting with Illuminating Engineering Society. February 16. Attendance 94.

Denver

Radiation, by Paul Luckenbach, General Electric Company. Joint meeting with the A. S. M. E., A. C. S., Colorado Scientific Society, and Teknik Club. February 6. Attendance 160.

Detroit-Ann Arbor

Electric Power Cables, by G. B. McCabe, Detroit Edison Co., and L. F. Hickernell, Allied Engineers, Inc. This subject was divided into two parts; Mr. McCabe outlined the manufacture, construction, installation, operation, and recent improvements in design, and Mr. Hickernell spoke on the application and specifications. Slides were used to illustrate the design and use of many kinds of cable. January 20. Attendance 200.

The Detroit Toll Board, by E. C. Balch, Michigan Bell Telephone Co. Preceding this meeting, there was an inspection trip through the Detroit Toll Board. February 17. Attendance 200.

Indianapolis-Lafayette

The Deion Breaker, by B. P. Baker, Westinghouse Electric & Mfg. Co. Mr. Baker discussed the theory underlying the construction and uses of the Deion air breaker and Deion grid breaker. Illustrated. February 20. Attendance 62.

Iowa

Electric Eye, Stroboscope, and Televox, by H. B. Stevens, Westinghouse Elec. & Mfg. Co. Apparatus was used to demonstrate the use of the Electric Eye and Televox. Joint meeting with the Iowa State College Branch. February 6. Attendance 339.

Ithaca

Outdoor Lighting, by E. H. Powell, General Electric Co. February 20. Attendance 35.

Lehigh Valley

Recent Developments in Generation and Transmission of Electric Power, by R. C. Bergvall, Westinghouse Electric & Mfg. Co. Outline of recent developments in electrical equipment to promote system stability under faulty or abnormal conditions. Meeting held at Hotel Casey, Scranton, Pa. February 4. Attendance 93.

The Future of Vacuum Tubes, by Dr. Albert W. Hull, General Electric Co. Joint meeting with the Engineers Club, held at Hotel Easton, Easton, Pa. February 27. Attendance 175.

Los Angeles

Dynamic Power Limits of Transmission Systems, by Wm. S. Peterson, Los Angeles Bureau of Power & Light. Mr. Peterson used the Griscom Mechanical Devices for illustrating stability problems, and also used a number of slides showing methods of calculation. Discussion followed. February 17. Attendance 76.

Louisville

Speed, Unemployment, and Progress, by Dr. William McClellan, vice-president, Stone & Webster Engg. Corp. February 20. Attendance 52.

Madison

Joint meeting with the University of Wisconsin Branch, at which the following papers were presented by students:

Automatic Oscillographs, by J. D. Cobine;

Trends in Electrical Construction, by R. J. Nickles, Jr.;

Copper-Oxide Rectifiers, by John L. Jones. February 18. Attendance 55.

Memphis

The Operation of the Distribution System of the Memphis Power & Light Co., by H. E. H. Martin, chief dispatcher, and W. A. Gentry, supt. of Distribution Operation Dept. of the above company. Two films entitled "Voltage Regulators," and "Oil Circuit Breakers." February 10. Attendance 34.

Speed, Unemployment, and Progress, by Dr. William McClellan, vice-president, Stone & Webster Engg. Corp., March 9. Attendance 84.

Minnesota

Electrification of the Cascade Tunnel, by J. E. Hawe, Great Northern Railway Co. Illustrated with moving pictures. March 4. Attendance 100.

Niagara Frontier

Interruption of High Currents at Low Voltages, and Application of Research to Development of Low-Voltage Air Circuit Breakers, by Knute Falck, I. T. E. Circuit Breaker Co. Illustrated. Film—"Building New York's Newest Subway." Dinner in honor of the speaker at the Hotel Niagara. February 20. Attendance 70.

Oklahoma City

Inductive Coordination of Communication and Electric Supply Equipment, by E. B. Jennings, Southwestern Bell Telephone Co., and C. E. Bathe, Oklahoma Gas & Electric Co. Dinner preceded the meeting. January 26. Attendance 54.

Recent Technical Developments in the Electrical Industry, by I. T. Monseth, Westinghouse Elec. & Mfg. Co. Illustrated with a number of pictures of developments made by the above company during the past year. February 23. Attendance 60.

Philadelphia

Some Developments and Applications in Electrical Communications, by R. D. Parker, American Tel. & Tel. Co. March 9. Attendance 225.

Pittsburgh

Research By-Products, by Dr. Phillips Thomas, Westinghouse Elec. & Mfg. Co. Mr. Thomas described and demonstrated a number of unusual applications of photo- and grid-glow tubes and other electronic devices. Joint meeting with I. R. E. and Engineers Society of Western Pennsylvania. February 9. Attendance 236.

Pittsfield

Color Photography, by Glenn E. Mathews, Eastman Kodak Co. Illustrated with slides and movies. February 17. Attendance 400.

River of Mystery—The Orinoco, by Dr. Herbert S. Dickey, Explorer and Scientist, Museum of the American Indian. Dinner preceded the meeting. March 3. Attendance 900.

Portland

Joint dinner meeting with the Oregon State College Branch, at which the following papers were presented by students:

The Characteristics of Pentode Tubes, by N. G. Reetz;

A High Voltage Corona Rectifier, by D. C. Foster and Wm. R. Bullis;

A Per Cent Registration Calculator for Watthour Meters, by C. E. Boucher. February 30. Attendance 85.

Artificially Generated Sun Light, by Paul Luckenbach, General Electric Co. Illustrated with lantern slides. March 3. Attendance 140.

Rochester

Materials Handling, by C. B. Crockett, Industrial Truck Association. Mr. Crockett stressed the importance of scientific handling of materials in large industrial plants and its cost and effect on production. Joint meeting with the I. R. E., A. S. M. E., R. E. S. October 9. Attendance 89.

The Advantages of Increased Power for Clear Channel Broadcasting Stations, by O. H. Caldwell, editor of *Electronics*;

Extending the Radio Frequency Spectrum, by A. H. Taylor, director, Naval Research Laboratories. Joint meeting with the I. R. E. November 21. Attendance 231.

Recent Achievements in Electrical and Steam Generation, by E. M.

Gilbert, W. S. Barstow & Co. Joint meeting with the I. R. E., A. S. M. E., and R. E. S. January 8. Attendance 208.

The Story of Commercial Enameling, by James H. Snyder, Pfaudler Co. Mr. Snyder described the difference between glass and paint enameled goods and demonstrated the Pfaudler method of mixing glass enamel. Joint meeting with the I. R. E., A. S. M. E., and R. E. S. January 22. Attendance 83.

Communism in the Abstract, by Colonel Hugh L. Cooper. Slides were used to illustrate the various engineering projects which Colonel Cooper has undertaken in Russia, and particularly the construction of the dam on the Dnieper River. Joint meeting with the I. R. E., A. S. M. E., and R. E. S. February 5. Attendance 416.

Making of Radio Tubes, by Paul T. Weeks, Raytheon Production Corp. Mr. Weeks analyzed the manufacturing end of the radio tube industry explaining, by the use of slides, the entire process from the manufacture of the elements to the finished tube assembly. Joint meeting with the I. R. E., A. S. M. E., and R. E. S. February 12. Attendance 77.

Transoceanic Telephony, by Henry Nicholson, Lyddon, Hanford & Kimball Co. Luncheon with the I. R. E., A. S. M. E., and R. E. S. sponsored by the A. I. E. E. January 6. Attendance 43.

What Can Retraining Do for Unemployment, by John A. Randall, president, Mechanics Institute. Luncheon with the I. R. E., A. S. M. E., and R. E. S., sponsored by the A. I. E. E. January 13. Attendance 50.

One Year's Progress in City Manager Government, by Stephen B. Story, city manager. Luncheon with the I. R. E., A. S. M. E., R. E. S., sponsored by the A. I. E. E. January 20. Attendance 66.

Telephone Traffic in Rochester, by John P. Boylan, Rochester Telephone Corp. Luncheon with the A. S. M. E., I. R. E., and R. E. S. January 27. Attendance 66.

St. Louis

Modern Developments in Large Waterwheel Generators and Synchronous Condensers, by Marvin W. Smith, Westinghouse Electric & Mfg. Co. Illustrated with slides. February 18. Attendance 85.

San Antonio

A. E. Allen, General Electric Co., discussed some of the recent developments of the electrical industry. Films were shown entitled "The Trend in Turbine Design," and "The Trackless Trolley Bus." February 16. Attendance 62.

Speed, Unemployment, and Progress, by Dr. William McClellan, vice-president, Stone & Webster Engg. Corp. March 4. Attendance 92.

Schenectady

Vacuum Tubes in Electrical Engineering, by W. C. White, General Electric Co. Illustrated with demonstrations. January 16. Attendance 200.

The World Background of American Business, by Charles A. Eaton, Member of Congress from New Jersey, and Member of the House Foreign Affairs Committee. February 6. Attendance 75.

The Manufacture of Iron and Steel, by G. A. Richardson, Bethlehem Steel Co. Moving pictures showing in detail the manufacturing methods in use in the steel industry were presented. February 20. Attendance 260.

Sharon

Recent Interesting Aeronautical Developments, by Samuel P. Mills, N. Y. University. Illustrated with slides and film entitled "Mexico." March 3. Attendance 227.

Spokane

A Résumé of Recent Developments in Predetermination of System Performance, by Dean H. V. Carpenter, State College of Washington. Discussion followed. February 27. Attendance 20.

Toledo

The Flying Telephone, by F. M. Ryan, Bell Telephone Laboratories, Inc. Illustrated with lantern slides, motion pictures, and demonstrations. February 17. Attendance 350.

A New Combustion Indicator, by Max Neuber, Motormeter Gauge & Equipment Co.;

Vacuum Treatment of Insulating Oils, by R. P. Dunmire, Buckeye Laboratories, Inc. March 6. Attendance 60.

Toronto

Applied Psychology, by Prof. S. N. F. Chant, University of Toronto. Considerable discussion followed this talk. Joint meeting with the Engineering Institute of Canada. February 12. Attendance 180.

Operation and Maintenance of Generating Stations, by A. S. Robertson, Hydro-Electric Power Commission. Illustrated with slides. February 27. Attendance 132.

Urbana

Lighting Architecture, by H. S. Logan, Holophane Co. Illustrated with slides and film entitled "Making Mazda Lamps." February 18. Attendance 120.

Utah

Television, by S. W. Pixton, Mountain States Tel. & Tel. Co. Mr. Pixton gave an illustrated lecture upon the history and developments of television, particularly from the standpoint of the Telephone Co. Informal dinner preceded the meeting. February 16. Attendance 80.

Vancouver

Joint meeting with the University of British Columbia Branch, at which the following papers were presented by students;

Manually-Operated Telephone Exchanges, by J. W. Smith;

Incandescent Lamps, by D. Smith;

Mercury Arc Rectifiers, by M. A. Thomas. March 2. Attendance 50.

Washington

Television, Its Fundamental, Physical and Psychological Principles, by Dr. J. O. Perrine, associate editor, *Bell System Technical Journal*, Dr. Perrine demonstrated the photoelectric cell and neon lamp. March 10. Attendance 260.

Worcester

Power Factor and Its Relation to Induction Motor Applications, by Prof. H. A. Maxfield, Worcester Polytechnic Institute. February 25. Attendance 30.

Past Branch Meetings

University of Akron

Underground Power Distribution Systems, by G. E. Buffington, student. Frank Marcinkoski, student, gave a demonstration of shock resuscitation. February 26. Attendance 10.

Alabama Polytechnic Institute

Detecting Rail Fissures, by J. M. Johnson, student. Mr. Jager, student, gave a description of his summer work as a mechanic in the mines. February 12. Attendance 15.

University of Alabama

Methods of Breaking Arcs, by Prof. F. R. Maxwell, Jr., counselor;

Electric Welding, by C. Hendrickson, student;

Pile Bridges, by W. G. Gable, student. December 15. Attendance 8.

Layout of Anniston Primary Substation, by Paul Clark, student;

Attention Paid to Safety by Large Companies, by W. H. Croft, student. January 12. Attendance 7.

Power Rates, by W. G. Gable, student;

Synchronous Condensers, by Paul Clark, student;

Electric Railways, by C. Hendrickson, student. January 26. Attendance 10.

Electrical Engineering in Aviation, by Prof. Leslie Walker. February 9. Attendance 8.

Business meeting. February 23. Attendance 8.

Professional Relationships, by Dr. Benjamin A. Wooten, head, Physics Dept.;

Opportunities in the A. I. E. E., by Prof. Fred R. Maxwell, Jr., counselor. February 27. Attendance 43.

University of Arkansas

Discussion of plans for Engineers' Day. February 18. Attendance 22.

Armour Institute of Technology

Asbestos Insulated Wire and Cable, by William Tierney, Rockbestos Products Corp. February 20. Attendance 52.

Talking Motion Pictures, by H. Merrill Smith, Electrical Research Products, Inc. March 6. Attendance 60.

University of British Columbia

Joint meeting with the Vancouver Section at which three papers were presented by students. (See report under "Past Section Meetings.")

Polytechnic Institute of Brooklyn

A-C. Distribution, by James G. Grover, student;

The Trend in A-C. Transmission, by Frank Powers, student;

Cathode Ray Oscillograph, by R. G. O'Sullivan, student. Frank Powers was awarded first prize and Robert G. O'Sullivan second prize. February 17. Attendance 18.

The Advantages Gained by the Young Engineer who Joins a Technical Society, by Roy V. Wright, president A. S. M. E. Joint meeting of the four technical societies. February 19.

Michael Faraday, by Leon Danner, student;

X-Ray Crystallography, by Sam Siegel, student;

A New Method of Scanning for Television, by Ivan Block, student. Ivan Block won first prize and Sam Siegel second prize. March 2. Attendance 25.

California Institute of Technology

L. H. Means, General Electric Co., outlined the problems met by industry in dealing with its operating personnel. He also gave a brief description of the General Electric Co. and its policies and practises toward employees. February 17. Attendance 52.

University of California

Initiation banquet at which the following papers were presented:

Why I Joined the A. I. E. E., by J. J. Cassidy, Jr., student;

Latest Developments in Electrical Engineering, by P. B. Garrett, Westinghouse Electric & Mfg. Co., and chairman San Francisco Section, A. I. E. E. February 3. Attendance 50.

New Developments in Toll Transmission, by C. V. Fowler, Pacific Tel. & Tel. Co. February 25. Attendance 38.

Case School of Applied Science

Electrical Knowledge of Faraday's Time, by Dr. W. E. Wickenden, president, Case School of Applied Science;

Faraday's Contributions to Science, by A. Friedman, student;

Faraday, the Man and His Life, by K. Spangenberg, student. Dinner meeting. March 3. Attendance 60.

Clemson Agricultural College

Life of Steinmetz, by C. V. Rentz, student;

75-Kv. Submarine Cable, by C. J. Davenport, student;

Miniature Switchboards, by L. W. Foster, student;

Radio Telephone Service to Ships at Sea, by C. DuRant, student;

Current events discussed by H. S. Montgomery. January 8. Attendance 24.

Life of Watt, by J. P. Littlejohn, student;

Football Field Illumination, by A. B. Coggins, student;

Current events discussed by G. H. Epting, student. January 22. Attendance 20.

Colorado State Agricultural College

Business meeting. February 9. Attendance 12.

The Application of Electricity in the Rayon Industry, by Prof. D. Bachelder. January 28. Attendance 13.

University of Colorado

Federal Regulation of Radio, by G. W. Earnhart, asst. radio inspector, Radio Commission. February 18. Attendance 58.

Carrier-Current Pilot of the Vincent 220-Kv. Transmission Line of the Southern California Edison Co. Ltd., by F. B. Doolittle, Southern California Edison Co., Ltd. February 23. Attendance 70.

An Explanation and Demonstration of Photophone Equipment, by A. S. Anderson, General Electric Co. Films—"The Electric Ship," "A Trip Through the Cascade Tunnel," and "Radio Active Rays." March 4. Attendance 325.

Cooper Union

Symposium on Electro-optics, by A. Ginsberg, D. Briansky, and G. Kosolopoff, students. Illustrated by experiments. March 4. Attendance 32.

Cornell University

Electricity in Railway Transportation, by R. R. Brainard, Branch secretary;

Trolley Buses, by O. K. Williams, student;

A Canadian Canoe Trip, by R. E. Nelson, student. February 18. Attendance 16.

University of Denver

Railway Electrification, by Frank Nutt, student. January 13. Attendance 24.

Film—"Building New York's Newest Subway." January 27. Attendance 33.

Photometers, by Louis Duval, student;

Hunting of Synchronous Machines, by F. W. Olmsted, Branch secretary. February 3. Attendance 21.

Film—"On the Pathways of Progress." February 10. Attendance 25.

High- and Low-Frequency Oscillators, by G. H. Lovins, student. February 17. Attendance 15.

University of Detroit

Inspection trip to the Del Ray power house and the Waterman substation of the Detroit Edison Co. January 15. Attendance 40.

Television, by H. Folkrod, Michigan Bell Telephone Co. Film—"History of Wireless." February 12. Attendance 75.

Drexel Institute

My Work in the Lightning Laboratory of the Pennsylvania Power & Light Co., by H. C. Werner, student. February 10. Attendance 18.

Philadelphia Electric's Present Transmission System, by W. W. Woodruf, Philadelphia Electric Co. March 3. Attendance 34.

University of Florida

The History and Development of Short-Wave Transmission in Radio, by R. E. Herrick, student;

The Construction of Audio Transformers, by R. M. Weinkle, student. March 9. Attendance 38.

Georgia School of Technology

Film—"The Single Ridge." February 11. Attendance 95.

Harvard University

Corrective Research, by F. V. Weeks, student;

A Summer with Westinghouse, by C. W. Waldow, student;

Between Students, by J. L. Beaver, student. March 4. Attendance 17.

University of Idaho

Film—"Construction of Wire." January 28. Attendance 63.

Two talks by students. February 3. Attendance 35.

Film—"Wizardry of Wireless." February 4. Attendance 55.

Time Pieces, by Glenn Gage, student. Talk by Professor J. H. Johnson, counselor. February 17. Attendance 37.

Motor Characteristics, by H. L. Vincent, General Electric Co. March 3. Attendance 37.

Kansas State College

H. M. Lowe, who recently returned from three years' work in South America related his experiences while there. Election of officers. February 5. Attendance 105.

University of Kansas

Howard Sutton, student, gave a technical report on a Westinghouse Relay for the control of transformers in parallel, after which he presented the relay to the electrical department for research work.

Rectification of Alternating Current Waves, by B. Brown, student. February 26. Attendance 45.

University of Kentucky

Inspection trip through the local telephone exchange. March 5. Attendance 41.

Lafayette College

Business meeting. March 7. Attendance 17.

University of Louisville

The Life of Edison, by E. B. Wagner, student;

Deion Circuit Breakers, by C. R. Bost, student. Illustrated. February 13. Attendance 21.

Marquette University

Debate between Mr. Horowitz and H. Jossell, students, on Coeducation at Marquette. Mr. Harriss of South Africa related living conditions in his home land. Joint meeting with the A. S. C. E. and A. S. M. E. Branches. December 18. Attendance 49.

Welding Generators—Their Construction and Applications, by K. L. Hansen, Northwestern Manufacturing Co. Joint meeting with the School of Engineering of Milwaukee Branch. January 7. Attendance 21.

Massachusetts Institute of Technology

Illumination and Color, by K. J. Germeshausen, student;

Broadcasting Development, by A. E. Cullum, student. Dinner preceded the meeting. February 19. Attendance 50.

Inspection trips to the General Electric Company in East Boston and West Lynn. March 4. Attendance 32.

Michigan College of Mining and Technology

Discussion of plans and appointments of committees for electrical show. February 17. Attendance 74.

Michigan State College

Film—"The Single Ridge." February 24. Attendance 25.

School of Engineering of Milwaukee

The Radio Control of Garage Doors, by Mr. Nethercut, Barber-Colman Co. Demonstrated.

The Theory of the Photoelectric Cell, by Mr. Greisel, student. Karl Werwath, student, reviewed some of the latest developments in the electrical field. February 11. Attendance 75.

Missouri School of Mines and Metallurgy

Two films entitled "The Benefactor," and "Thomas A. Edison." December 18. Attendance 23.

Life of Faraday, by G. L. Leisher, student;

Description of the Life of Steinmetz, by Prof. I. H. Lovett, Counselor. M. R. James, student, gave a talk on his experiences while employed by the Union Electric Co. January 28. Attendance 16.

Business Meeting. February 11. Attendance 13.

Films—"Atomic-Hydrogen Welding" and "Aircraft Accessories." February 25. Attendance 167.

The Desire to Do a Thing, by Branch Rickey, vice-president of the St. Louis Cardinals. February 27. Attendance 423.

University of Missouri

Annual Dinner. Short talk by J. S. Palmer, Kansas City Power & Light Co. February 24. Attendance 43.

Marine Propulsion, by F. V. Smith, General Electric Co. Joint meeting with the A. S. C. E., and A. S. M. E. Branches. March 9. Attendance 50.

Montana State College

Film—"From Mine to Consumer." February 12. Attendance 152.

Why An Engineer Should Take Public Speaking, by Walter J. Williams, student;

White Lights North of Arctic Circle, taken from *Power Plant Engineering*, presented by Herbert Archibald, student;

Some Aspects of Federal Regulation of Water-Power Development, taken from Electrical Engineering, presented by James Pepper, student;

Detecting Hidden Fissures in Rails, taken from Electrical Engineering, presented by Ward Rightmire, student. February 19. Attendance 143.

Artificial Sunlighting Now Challenges the Sun, taken from *Electrical World*, presented by E. N. Blannin, student;

The Development of Lighting During the Year 1930, taken from *General Electric Review*, presented by Edward Fisher, student;

Gasoline Pump Motors, taken from *Electric Journal*, presented by Leonard Estey, student. February 26. Attendance 129.

Electricity and Light During 1930, taken from *Electrical World*, presented by Armin J. Hill, student;

Floating Electric Power Plant, by Homer T. Lambdin, student;

Constant-Voltage Regulators, by Paul McAdam, student. March 5. Attendance 134.

University of Nebraska

Oil Circuit Breaker Phenomena, by G. W. Swallow, American Brown Boveri Co. Inc. Film—"Electric Locomotives and Trains in Switzerland." February 3. Attendance 55.

Inspection trip through the U. S. Government Radio Monitor Station, conducted by Benjamin Wolf, manager of the Station; also through the Grand Island Sugar Beet Factory, conducted by U. Anderson, chemist. February 8. Attendance 28.

Picture Transmission by Wire, by Cecil Donley, Lincoln Telephone & Telegraph Co. February 18. Attendance 40.

Opportunity for Engineers Today, by Roy V. Wright, president, A. S. M. E. March 3. Attendance 120.

University of Nevada

Electricity and Its Application to the Mining Industry, by J. A. Fulton, director, Mackay School of Mines. February 4. Attendance 16.

Electric Water Purifiers, by Chester Elliott, student;

New Developments in Vacuum Tubes, by Jack Hough, student. February 11. Attendance 15.

Electron Tubes, by H. C. Stanley, General Electric Co. Illustrated with motion pictures. February 18. Attendance 68.

Newark College of Engineering

Direct-Coupled Amplifiers, by W. B. Wible, student;

Mercury Vapor Turbines, by S. F. Spence, student;

Generator-Voltage Regulation, by G. McSweeney, student. February 24. Attendance 32.

University of New Hampshire

Films—"The Potter's Wheel," "Revelations by the X-Ray," and "The Cat and the Kit." January 10. Attendance 36.

The Photoelectric Cell and Some of Its Applications, by J. J. Carlen, student. January 17. Attendance 36.

Electrification of Railways, by F. M. Jones, student. January 24. Attendance 33.

Harnessing Ocean Temperatures, by K. S. Savage, student;

A New Radio Battery that Breathes Air, by O. K. Reid, student;

Explanation and Demonstration of Magnetic Arc Blow-Out, by G. R. Walden, student;

Why Fraternities Should not Exist on a College Campus, by C. A. Dolloff, student;

Why Fraternities Should Exist on a College Campus, by H. R. Wood, student. January 31. Attendance 30.

Aluminum Electrolytic Condenser and Lightning Arrester, by P. J. Stafford, student;

Radio Programs by Electrical Transcription, by R. M. Sawyer, student;

Flood Control in the Mississippi Valley, by J. J. Cunningham, student. February 7. Attendance 34.

Films—"Turbines," and "Dynamic America." February 21. Attendance 35.

Induction Generators, by R. Osgood, student;

Aurora, The Elusive Mystery of Science, by F. Dickey, student;

The Polarized Bell, by C. Matoian, student;

Operation of D-C. Generators in Parallel, by L. Barker, student;

Why A-C. Current Leads the Voltage 90 Degrees with a Condenser in the Circuit, by F. Perkins, student. February 28. Attendance 34.

University of New Mexico

The Life and Work of Oliver Heaviside, by S. Fish, student;

Control by Radio, by H. Mendenhall and E. Huffman, students. February 26. Attendance 11.

College of the City of New York

Discussion of Branch activities. February 19. Attendance 15.

Business meeting. March 5. Attendance 18.

University of North Carolina

Block Signals, by A. C. Robertson, student;

Electrical Experiences, by O. J. McCall, student. February 12. Attendance 30.

Union Management Cooperation Through Research, by Morris L. Cooke, consulting engineer. Joint meeting with the Taylor Society. February 25. Attendance 90.

North Dakota State College

Annual Engineers' Banquet. My 30 Years' Experience Since Graduating from College, by M. S. Hyland, consulting engineer, Fargo, N. D. Film—"The Age of Riveted Steel." February 19. Attendance 108.

Preservation of Wood, by Wayne Curtis, student;

Film—"Blasting the Water Highways of America." February 25. Attendance 54.

University of North Dakota

General Electric Motors and Motor Application, by C. W. Randall, General Electric Co. February 11. Attendance 21.

Transportation Electrification, by Eugene Becker, student. March 4. Attendance 16.

University of Notre Dame

Thunderstorms and Lightning Discharge, by Prof. Daniel Hull, Dept. of Physics;

Resonance, by Edward Coomes, student;

Cross-Talk Elimination, by D. D. Mohler, student;

Life of Faraday, by A. V. Alvino, student. Patrick Murray presented the usual news digest. February 16. Attendance 68.

Turning the Light of Everyday Experience on the Economics of Today's Business and Related Activities, by L. B. Andrus, Central Indiana Power Co.;

Practical Telephony, by Henry Culver, student;

The Mercury Arc Rectifier, by Hugh Ball, student. Patrick Murray presented the usual news digest. March 2. Attendance 80.

Ohio Northern University

Film—"Government Aviation Developments." February 19. Attendance 38.

Discussion of future meetings and nomination of new officers. February 26. Attendance 24.

Looking Ahead in Aviation, by D. Cottrell, student. Election of officers as follows: O. R. Jacobs, president; B. Wyant, vice-president; W. Gideon, secretary; O. Hawes, treasurer. March 5. Attendance 18.

Ohio State University

Vacuum Tubes in Industry, by S. D. Fendley, General Electric Co. February 26. Attendance 22.

Ohio University

Film—"Induction Voltage Regulator." February 16. Attendance 8.

Oklahoma A. & M. College

Discussion of plans for the electrical show. February 5. Attendance 19.

Dry Cells—Their Manufacture and Use, by Paul Ratliff, student. Illustrated. February 12. Attendance 30.

Oregon State College

Safety in the Industries, by A. E. Eicken, National Safety Council. Illustrated with slides. February 16. Attendance 13.

Joint meeting with the Portland Section at which three papers were presented by students. (See report under "Past Section Meetings").

Discussion of Branch activities. March 2. Attendance 21.

University of Pennsylvania

The Thyratron Multi-Bopper Circuit, by Newbern Smith, student. February 19. Attendance 22.

Pratt Institute

Electric Railways, by J. L. Thomson, student;

Production of Aluminum, by N. J. Cherry, student. February 19. Attendance 15.

Purdue University

The Deion Circuit Breaker, by B. P. Baker, Westinghouse Electric & Mfg. Co. Illustrated with slides. February 10. Attendance 90.

Rensselaer Polytechnic Institute

Artificial Transients of Transmission Lines with Particular Reference to Performance of Lightning Arresters, by K. B. McEachron, General Electric Co. Illustrated with slides. February 10. Attendance 70.

Rose Polytechnic Institute

Illumination of Aviation Fields, by Bruce Wells, student. Film—"Aviation Lighting." March 4. Attendance 29.

University of Santa Clara

The Historical Development of the Allis-Chalmers Mfg. Co. and Their Motor and Dynamo Products, by William F. Snyder, Allis-Chalmers Mfg. Co. January 29. Attendance 105.

University of South Carolina

The Kaplan Automatic Adjustable Blade Turbine, by R. Brooks, student;

A Laboratory Method of Measuring the Capacity of Small Condensers, by C. L. Fishburne, student. February 16. Attendance 26.

The Vacuum-Tube Voltmeter, by J. W. Palmer, student;

Will You Lose Your Job Because of a New Machine, by J. B. Dent, student;

Electronic Tubes—Their Present and Future, by J. Oberschain, student. February 23. Attendance 30.

Business meeting. March 2. Attendance 9.

The Development of Motion Pictures, by R. Phillips, student;

Baron Munchausen Out-Lied with Truth, by David Peele, student. March 9. Attendance 29.

University of Southern California

Business meeting. February 4. Attendance 30.

L. A. Buese, Los Angeles Gas & Elec. Corp., discussed the remote control of substations by means of a step-by-step relay system. February 11. Attendance 32.

Aircraft Communication, by Del Mar Wright, Western Air Express and Transcontinental Air Transport, Inc. February 18. Attendance 32.

The Electrical Measurement of Acoustical Properties, by D. P. Loye, Electrical Research Products, Inc. February 25. Attendance 27.

STREET LIGHTING, by O. W. Holden, Los Angeles Bureau of Power & Light. March 4. Attendance 30.

Stanford University

TRANSFORMER CONSTRUCTION, by W. C. Smith, General Electric Co. February 4. Attendance 21.

Stevens Institute of Technology

LIFE OF JOSEPH HENRY, by Donald Naughton, student. February 24. Attendance 21.

Syracuse University

SOME EARLY A. I. E. E. MEETINGS, by Prof. C. W. Henderson, counselor. February 13. Attendance 23.

MEASUREMENT OF LIGHTNING DISTURBANCES ON TRANSMISSION LINES, by John Henderson, student;

THE BRIDGE TRANSFORMER, by Richard Stone, student. February 20. Attendance 25.

HYDROGEN-COOLED GENERATORS, by Donald Brown and Ernest Wood, students;

COOLING FINS, by Edward Schweitzer and Stanley Scerbinski, students. February 27. Attendance 25.

DISTRIBUTION SYSTEM OF SYRACUSE LIGHTING CO., by L. L. Cross, Syracuse Lighting Co. March 6. Attendance 24.

University of Tennessee

Debate—COPPER VERSUS ALUMINUM CABLES FOR TRANSMISSION LINES, by J. M. Brooks and J. Barnwell, students. February 19. Attendance 21.

University of Texas

STEAM GENERATING EQUIPMENT, by O. K. Irvine, student;

ELECTRICAL GENERATING EQUIPMENT, by D. Sussin, Branch secretary;

SWITCHBOARD EQUIPMENT, by E. W. Toepperwein, student. February 12. Attendance 18.

University of Utah

TELEVISION, by Seth Pixton, illustrated. February 24. Attendance 25.

University of Vermont

THEORY OF THE STENODE RADIOSTAT, by A. L. Howard, student. February 24. Attendance 21.

Virginia Military Institute

Film—"Conowingo." February 18. Attendance 50.

500 M. P. H.—CAN'T BE DONE, by F. A. Tyler, student;

WHAT THE ELECTRICAL INDUSTRIES THEMSELVES EXPECT OF THE ELECTRICAL STUDENT, by R. E. Fort, student;

THE SUPER-MAGNETIC FIELD, by E. R. Trapnell, Student. February 19. Attendance 46.

Virginia Polytechnic Institute

Discussion of Branch activities and of the recent lecture given by S. P. Grace, assistant vice-president, Bell Telephone Laboratories, Inc., entitled MARVELS OF SOUND TRANSMISSION. February 12. Attendance 15.

TESTING OF DRY-CELL BATTERIES AS DONE AT THE BUREAU OF STANDARDS, by M. H. Mills, student. February 26. Attendance 18.

Washington State College

Election of officers as follows: L. N. Hatfield, president; A. Keto, vice-president, G. C. O'Brien, secretary; H. Stingle, treasurer. January 21. Attendance 29.

Washington University

Discussion of Branch activities. February 26. Attendance 15.

West Virginia University

The following talks were given by students;

ELECTRICITY IN THE CEMENT INDUSTRY, by C. J. DeLavey;

INDUSTRY VERSUS TECHNICAL EDUCATION, by R. W. Blair;

THE GROWTH OF 1930, by R. N. Kennedy;

AERONAUTICAL RADIO COMMUNICATION, by C. J. McCormack;

IMPROVEMENTS TO MAKE ELEVATORS FASTER AND SAFER, by J. N. Simpson;

AIR-CELL BATTERIES, by K. De Moss;

ELECTRIFICATION OF B. & O. RAILROAD, by R. C. Warder;

90 MILES PER HOUR IN A TROLLEY CAR, by J. M. Morgan. February 10. Attendance 25.

The following talks were given by students:

FLOPS BY FAMOUS INVENTORS, by H. V. Locker;

ELECTRICAL INDUSTRIES, by M. L. Sprigg;

GENERAL PRINCIPLES OF SOUND RECORDING, by V. S. Monteith;

LOCATING HIDDEN FISSURES IN RAILS, by S. I. Boone;

INDUCTION TYPE OF RELAY, by A. H. Goddins;

REMOVING SLEET AND ICE FROM TRANSMISSION LINES, by L. P. Kerwin;

VARIED USES OF THE PHOTOELECTRIC CELL, by W. C. McMillion. February 17. Attendance 27.

The following talks were given by students;

INDUCTION OF ELECTRIC CURRENT BY MICHAEL FARADAY, by P. N. Vannoy;

EARLY LIFE AND TRAINING OF FARADAY, by H. O. Webb;

FARADAY'S EXPERIMENTS, by J. E. Newcomer;

VIEWS OF FARADAY, by P. Shaff;

LIFE OF HENRY, by S. B. Wolfe;

SUMMARY OF HENRY'S CONTRIBUTIONS, by T. E. Palmer. February 24. Attendance 33.

University of Wisconsin

AUTOMATIC OSCILLOGRAPHS, by J. D. Cobin, student;

TRENDS IN ELECTRICAL CONSTRUCTION, by R. J. Nickles, Jr., student;

COPPER OXIDE RECTIFIERS, by J. L. Jones, student. Joint meeting with the Madison Section, sponsored by the Branch. February 18. Attendance 55.

ORGANIZATION AND FUNCTIONS OF THE CONSTRUCTION DEPARTMENT OF COMMONWEALTH EDISON CO. OF CHICAGO, by Theodore Racheff, Branch secretary. Short talk on the life of Faraday given by Professor C. M. Jansky, counselor. November 26. Attendance 11.

University of Wyoming

LIFE OF FARADAY, by T. Hance, student;

LIFE OF JOSEPH HENRY, by A. Bucholz, student. Election of officers as follows: N. Sanders, Chairman; T. Hance, vice-chairman; Roy Perkins, secretary-treasurer. February 10. Attendance 13.

Yale University

Films—"Blasting the Waterways of America," and "The Single Ridge." Joint meeting with the A. S. M. E. Branch. February 10. Attendance 46.

THE SIMPLER TYPES OF LIGHTNING ARRESTERS, by L. A. Autuori, Branch secretary;

THE AUTO-VALVE AND THYRITE ARRESTERS, by R. A. Hackley, student;

THE USE OF THE KLYDONOGRAPH ON POWER AND TELEPHONE LINES, by E. R. Eberle, student. February 19. Attendance 13.

Engineering exhibition held jointly with the A. S. M. E. Branch. February 23. Attendance 540.

PUBLIC UTILITIES ACCOUNTING SYSTEM, by O. C. Rutledge, student;

RATE STRUCTURES AND SCHEDULES, by A. A. Watson, student;

ECONOMIC FACTORS OF ELECTRIC POWER INTERCONNECTIONS, by H. Geers, student. February 26. Attendance 13.

BIOGRAPHY OF MICHAEL FARADAY, by F. W. Wolff, student;

TECHNICAL ASPECTS OF FARADAY'S EXPERIMENTS, by P. Thomson, student;

BIOGRAPHY OF JOSEPH HENRY, by J. D. Upton, student;

THE TECHNICAL ABILITY OF JOSEPH HENRY, by L. Clare, student. R. M. Gerris, student, gave a history of the Sheffield Scientific School of Yale University. March 7. Attendance 28.

Employment Notes

Of the Engineering Societies Employment Service

Position Available

ASSISTANT to research engineer in automotive division of large manufacturing concern. College graduate in electrical engineering with GE or Westinghouse experience on electric automotive accessories, preferred. Apply by letter. Location, New England. W-2498.

Men Available

JUNIOR ENGINEER, 1930 graduate, B. S. and E. E. degrees. Practical experience in general electrical measurements and knowledge of radio receiver construction. Desires position in electrical or mechanical engineering where technical knowledge is principal requirement, as research, design, or testing. Location preferred, in or near New York City. C-8813.

ELECTRICAL ENGINEER, graduate of European technical college, with eight years' of varied and successful research experience in the United States. At present employed. Desires responsible position in the development or consulting department of a concern located in or near New York. B-6782.

GRADUATE ELECTRICAL ENGINEER, 31, married, with seven and one-half years' experience including: two and one-half years as engineer with manufacturer's service shop, two years university instructor, two years responsible position in manufacturer's engineering department and one year as electrician on station construction. Desires position with manufacturer, industrial concern or public utility. Available on short notice. C-1073.

GRADUATE ELECTRICAL ENGINEER, 25, single. Reared in the Orient, traveled widely, one year test course with motor manufacturer, one year sales experience on Pacific Coast. Desires permanent location with a company looking forward to an expansion in its foreign business. Available at once. Location, anywhere in United States. B-6945.

CONSULTING ENGINEER with long and successful experience in development and improvement of electrical devices including specialities in signaling, lighting, regulating, and railway fields. Desires additional connections. Especially interested in manufacturers' problems regarding new products and improvement of old products. C-8843.

ELECTRICAL ENGINEER, graduate Georgia Technology, 1930. Cooperative plan, worked alternate months, five years substation maintenance and office engineering. Rebuilding transformers, switches, lightning arresters, work with electric furnaces, rectifiers, motors, etc. Checking and mapping distribution systems, work orders, drafting. Single, excellent physical condition. Desires position, preferably with utilities. Location, immaterial. C-7847.

ELECTRICAL ENGINEER, B. S. degree from recognized Southern University, 24, single. Eighteen months on power transformer test, part of which was high-voltage and other experimental test. Desires position with future. Location and salary secondary to opportunity. C-8881.

PROFESSOR OF ELECTRICAL ENGINEERING, 49, 18 years' of successful teaching experience in both d-c. and a-c. circuits and machines, and theory of transmission. Denominational college. B. E. in E. E. and M. S. degrees. Location preferred, South. B-2675.

GRADUATE ELECTRICAL ENGINEER, 1930, 22, single, seven months on Westinghouse engineering course. Desires position with company in field of electrical or physical measurements and testing. Available at once. Location, immaterial. C-8875.

ELECTRICAL ENGINEER, graduate Rensselaer Polytechnic Institute, age 33. Five years with engineering department of large manufacturer of electric control apparatus. Four years with leading engineering firm as electrical designer on central station and industrial work. Specialized on switchboard and wiring design. Some sales experience. Now employed. Desires more responsible position. B-6274.

ELECTRICAL ENGINEER, bachelor and master degrees; 14 years' peculiarly broad experience in test, research and development, standardization, consultation, university teaching, executive work, personnel; familiar with both power and radio equipment and practise. Stability and opportunity primary; initial salary and location secondary. Available at once. C-4591.

ELECTRICAL ENGINEER, 32, married. Seven years with manufacturer on design of electric traction equipment and control apparatus. General engineer. Experience writing specifications, reports, technical papers. Teacher of mathematics. C-8896.

GRADUATE ELECTRICAL ENGINEER, B. S. Degree. One and one-half years with large electrical manufacturing concern in test and research departments. Also familiar with repair work on distribution transformers and other apparatus. Available on short notice. Location preferred, New England or eastern part of country. C-8075.

PROFESSOR OF ELECTRICAL ENGINEERING, 34, eight years' experience in teaching most branches of electrical engineering, state school. Holds broadcast class, limited operator's license. Five years' experience operation and maintenance of college broadcast transmitter; B. S. in E. E. and E. E. degrees. Location preferred, East, Middle West. Available school year 1931-32. C-8916.

ELECTRICAL ENGINEER, technical graduate, G. E. test and over 18 years' varied experience, including electrical manufacture; railway construction, valuation and maintenance; power-line construction and steam railroad electrification. Desires position with company doing consultation and construction engineering or with operating company. B-7456.

PROFESSOR OF ELECTRICAL ENGINEERING, 32, married, B. S. (E. E.) and E. E. Three years with General Electric Company, five years with public utility, four years' teaching and administrative experience in state university. Excellent references. Available for next academic year. Correspondence invited. C-7152.

ELECTRICAL AND ILLUMINATING ENGINEER, 41, married, 23 years' experience, wireman to superintendent, estimator and engineer, instructor in applied electrical engineering. Experienced in power station, commercial and industrial building wiring. Six years' engineering for architects, writing specifications, designing electrical installations, office buildings, theatres, hotels, schools, hospitals, industrial buildings. C-8460.

DRAFTSMAN-DESIGNER, electrical engineer, German Technical Institute, 32, married. Eight years' foreign, three and one-half years' American experience in design of electrical apparatus and radio receivers. Desires permanent, related position. Location preferred, Newark or New York. C-8787.

ASSISTANT PROFESSOR OR INSTRUCTOR IN ELECTRICAL ENGINEERING, eight years' teaching experience in d-c. and a-c. theory, electrical machinery, radio, dynamo laboratory, and electrical measurements; four years' commercial experience in power, lighting, radio and general electrical equipment design. Available for fall term. C-6302.

GRADUATE MAINTENANCE ENGINEER, 26, married; eight years' varied experience, operating steam turbines, high-voltage a-c. remote control board, hand switching, and power-house apparatus of all kinds. Also construction and electrical maintenance work of all kinds in chemical and cement plants. Now unemployed. Will accept first reasonable offer. C-8522.

PROFESSOR OF ELECTRICAL ENGINEERING, 40, six years' successful experience teaching practically all branches electrical engineering, state school. Considerable experience power, telephone work. One year switchboard engineering department of Westinghouse; B. S. in E. E. and E. E. degrees. Prefer location, Rocky Mountain, Pacific Coast States. Available school year 1931-1932. C-5021.

1929 GRADUATE heading university, B. S. E. E., desires position giving experience cable installation. One year's experience large power company laying out underground network distribution system. One year's experience rubber-insulated cables, electrical testing laboratory large cable manufacturer. Can handle men. Working knowledge French, Spanish; elementary knowledge German. Location, immaterial. C-6408.

ELECTRICAL DESIGNER, age 36, married. Ten years' public utility experience in steam and hydroelectric plants, substations and industrial plants. Also served four years as fire insurance inspector. Graduate of technical school on electrical and mechanical subjects. C-7979.

ELECTRICAL ENGINEER, 47, college graduate, married. Twenty-six years' experience as designing, report, power and executive engineer with three engineering firms. Experience includes cost estimating for plant and transmission facilities, design, construction supervision, operating economics with fuel and hydro plants, system planning for public utility and industrial properties. B-4553.

ELECTRICAL ENGINEER, 1930 graduate, desires position. Experience in drafting, radio service, electric-meter testing. Recently technical representative for large radio-phonograph concern. Excellent references. C-8578.

ELECTRICAL DESIGNER AND DRAFTSMAN, age 31, single. Eight years' public utility experience in steam and hydroelectric plants, substations and industrial plants. Graduate of technical school in mechanical and electrical engineering. Desires position with public utility or industrial company. C-4510.

DIRECTOR OF EDUCATION AND TRAINING with national technical corporation, formerly assistant professor of electrical engineering, 5 years at leading technological college. Experienced administration educational work. Desires position professor electrical engineering, head of department at medium sized or small college where development and expansion is possible, or associate professorship in large technical college. C-8967.

ELECTRICAL-MECHANICAL ENGINEER, graduate, age 34, married. Experienced, design, manufacture and application of motors and generators. Past five years in district sales office of large manufacturer, contacting central stations and large industrial concerns both in operating problems and sales promotion. Desires a job where initiative, energy, and results will count. B-9432.

ELECTRICAL FOREMAN, 38, married. Eighteen years' experience covering power plant, substation, industrial, construction and maintenance. Have headed these departments for years. Especially qualified to take charge of actual work under a busy executive. C-2028.

ELECTRICAL ENGINEER, 31, B. S. E. E. 1926. One year assistant electrical engineer making preliminary studies, investigations on hydroelectric projects; one year engineer electrical control of armament on aeroplanes; two years material inspection, street railway company; one year student engineer large public utility; two years' electric car shop experience. C-6077.

GENERAL ENGINEER, 27, married, A. B.; and B. S. in E. E. degrees. Experienced in steam power plants, water-works, industrial electrical equipment maintenance, underground power system construction and maintenance, and oil refinery equipment standardization and maintenance. Desires engineering position along line of experience that has possibilities for advancement. Location, immaterial. C-8982.

PLANT ENGINEER, age 47, married, two children, two degrees in E. E. Over twenty years' experience in design, construction, maintenance and operation of all mechanical equipment for buildings, building construction; factory facilities, steam and hydraulic power plants. Understands efficient handling of large groups of men. Location, South, Central West or Northeast. C-8868.

ELECTRICAL ENGINEER, 36, married, university graduate. Eighteen years' experience in design, construction, maintenance and operation of hydroelectric stations, distribution and transmission systems, also design and construction of steam stations. Last five years with large consulting firm. Initiative and ability to produce. C-8980.

GRADUATE ELECTRICAL ENGINEER, 33, eight years' experience in high-voltage research. Wishes position with switch manufacturer in design work. Location, anywhere. C-8981.

ELECTRICAL ENGINEER, 25, single. Cornell University graduate in E. E. Two years' drafting experience with large engineering concern. One year in manufacturing plant as assistant to plant engineer. Desires permanent position with a future with a utility or engineering company. C-8949.

GRADUATE ELECTRICAL ENGINEER, age 23, single, 21 months of Westinghouse Test on rotating machinery and control, B. S. in E. E. 1929, at present pursuing graduate study. Desires position as engineering instructor or in any electrical line offering a future. Available immediately. Eastern Location preferred. C-8966.

SALES AND EXECUTIVE ENGINEER, trained at Worcester Polytechnic Institute. Seven years' sales experience: straight sales eneneering, jobbing sales, sales management, saels promotion. Has contacted with electrical and mechanical companies. Traveled East, Middle West, South. Well acquainted with New England. C-5431.

ASSISTANT PROFESSOR OR INSTRUCTOR in electrical engineering. Three years development and research engineer on communication apparatus. Five years head of electrical department in large industrial school. At present on E. E. staff of recognized university, teaching electrical design and other electrical engineering subjects. Available in September. C-2893.

GRADUATE ELECTRICAL ENGINEER, age 28, married, with 8 years' industrial control, power plant design and construction supervision experience with contractor. Desires position with public utility or manufacturing concern's engineering or construction departments. Location desired, Middle West. C-4428.

GRADUATE ELECTRICAL ENGINEER, age 26, single, 4½ years' experience with Westinghouse Electric and Mfg. Co. including graduate student course and two engineering departments. Has done experimental and application work on industrial devices using electronic tubes, particularly photo-tubes. This includes some design work, technical correspondence and diagram drafting. Available early summer. C-8888.

GRADUATE ELECTRICAL ENGINEER, 25, obtaining Master's Degree in June, 1931, desires position as assistant professor or instructor in electrical engineering, or as research engineer. Four summers' employment with large utility company. Two years' teaching experience. Has had experience with development of remote-control apparatus. Available July 1, 1931. Location, United States. C-8994.

EFFICIENCY ENGINEER, industrial electrical graduate with broad experience in application of electric drive and design of complete power layout in plants. Experience also includes considerable time with power companies and refrigeration companies. Available on short notice. Location, immaterial. A-4018.

1929 GRADUATE, E. E. degree. Fourteen months on General Electric Test. Assignments covered work on radio and vacuum development and testing all types of electrical equipment. Available immediately. C-1879.

GRADUATE ELECTRICAL ENGINEER of Purdue University with 18 years' experience in design, construction, estimating, costs, valuation and appraisal of power plants, substations, transmission lines and industrial plants including five years in heavy electric traction and rapid transit work. Open for opportunity with future. C-8256.

GRADUATE ELECTRICAL AND MECHANICAL ENGINEER, 36, desires connection with public utility or industrial firm on power-station operation as engineer, or as assistant to superintendent or engineer. Ten years' experience in power plant test, operation, design, construction, and maintenance. Three years electrical engineer for industrial firm. Two years assistant to power engineer. B-8379.

ELECTRICAL ENGINEER, 28, married, 4 years out, now employed. One year power utility course, three years telephone and talking pictures. Previous experience as commercial radio operator. Would be valuable to concern requiring services of capable engineer. Position must be permanent with future. Location secondary factor. Best of references available. Correspondence invited. C-7902.

ELECTRICAL ENGINEER, graduate 1931, 26 years, single. Desires position in Mexico or South America. Speaks and writes Spanish. An engineering work in radio or any electrical enterprise with opportunity for advancement is desirable. References. C-8662.

ELECTRICAL ENGINEER, B. E. E., class 1918. Two years teaching, two years sales promotion, five years design power houses, substations, transmission, equipment specification and purchases, switchboards, control, etc. Four years plant engineer. Available April 1st. C-8942.

ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.	205 West Wacker Drive	31 West 39th St.
San Francisco	Chicago	New York
N. D. Cook, Manager	A. K. Krauser, Manager	W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

Men Available.—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

Opportunities.—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

Voluntary Contributions.—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

Answers to Announcements.—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

Membership

Applications for Election

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before April 30, 1931.

Engineering Literature

New Books

In the Societies Library

Among the new books received at the Engineering Societies Library, New York, during January are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

Applications of Interferometry. By W. Ewart Williams. N. Y., E. P. Dutton & Co., 1930. 104 pp., diagrs., 7 x 4 in., cloth. $.85.——This little book provides a useful description of the various types of interferometers and explains the principles of each type. The scientific and technical applications of interference methods are pointed out, and useful lists of references are given. The work is a useful introduction to the subject for engineers and physicists.

Das Buch der Grossen Chemiker, Bd. 2; von Liebig bis Arrhenius. By Günther Bugge. Berlin, Verlag Chemie, 1930. 559 pp., illus., ports., 9 x 6 in., cloth. 32 r. m.——The development of chemistry during the last century is well covered by this collection of biographies of great chemists, from Liebig to Arrhenius. Each biography gives the salient facts about its subject and points out clearly his contributions and their effect upon the growth of the science. The reader not only learns to know the individuals, but also gets a good grasp on the history of chemistry.

Economic Control of Engineering and Manufacturing. By Frank L. Eidmann. N. Y., McGraw-Hill Book Co., 1931. 402 pp., illus., diagrs., tables, 9 x 6 in., cloth. $4.00.——Points out problems of engineering and manufacturing which must be solved by economic analysis and presents methods of procedure for their solution. Among the matters discussed are the choice between different types of equipment, the determination of the economy of proposed changes in equipment, processes or methods, the proper amount of materials to keep in stock, the economic effects of artificial illumination, and similar problems.

L'Évolution et le Développement des Principales Industries depuis Cinquante Ans, 1880-1930. Issued by

Genie Civil as a special number. Paris, Jules-Lefebvre, 1930. 236 pp., illus., 14 x 11 in., paper. 25 fr.——In commemoration of its fiftieth anniversary, the "Génie Civil" has issued a special number devoted to a review of the progress of engineering during the half century. Forty-two articles by eminent specialists describe developments in public works, mining, agriculture, roadbuilding, railroads, etc. The publication is a valuable historical summary.

LEHRBUCH DER BERGWERKSMASCHINEN (Kraft- und Arbeitsmaschinen). By H. Hoffmann and C. Hoffmann. 2d edition. Berlin, Julius Springer, 1931. 402 pp., illus., tables, 11 x 8 in., cloth. 24 r. m.——A comprehensive treatise upon mining machinery, which not only describes the different machines used but also discusses the mine power plant and the distribution of power. Starting with a chapter on thermodynamics, the author discusses fuels, boilers and boiler plants, piping, steam engines and turbines, and internal-combustion engines. Hoisting machinery, pumps, compressors, compressed-air machinery, refrigerating and ventilating equipment, and electrical machinery are then described.

MACHINES ÉLECTRIQUES. By A. Mauduit. 4th edition. (Électrotechnique Appliquée). Paris, Dunod, 1931. 2 v., 1738 pp., diagrs., 10 x 7 in., bound, 306,50 fr.; paper, 284,50 fr.——These two large volumes by Professor Mauduit, of the University of Nancy, treat of the theory, testing and construction of electrical machines. Both a-c. and d-c. machines are included. The subject is treated both theoretically and practically, from the plant engineer's point of view rather than for the designer.

PHYSICS. By Oscar M. Stewart. Revised edition. Boston, Ginn & Company, 1931. 770 pp., illus., diagrs., 9 x 6 in., cloth. $4.00.——A thoroughly revised edition of a popular elementary college textbook. The book is intended especially for those who are studying physics as part of a general course in the arts and sciences and have no special training in mathematics. The book aims to give a good grasp of the fundamental principles of physics, to illustrate them by everyday examples, and incidentally to train the student in the scientific method of reasoning.

RADIATIONS FROM RADIOACTIVE SUBSTANCES. By Sir Ernest Rutherford, James Chadwick and C. D. Ellis. N. Y., Macmillan Company, 1930. 588 pp., illus., diagrs., tables, 9 x 6 in., cloth. $6.50.——This new work by the famous investigator of radioactive phenomena will be welcomed by all students of the subject. It is concerned not with the transformations of radioactive substances but with the rays that accompany the transformations and the effects that these radiations produce while passing through matter. A concise, connected account of our knowledge of the radiations is given, and the bearing of the results on the problem of the structure of the nucleus of the atom is discussed.

REPORTS AND PAPERS, 1930. American Society of Mechanical Engineers Research Committees. N. Y., A. S. M. E., 1931. Various pagings, illus., diagrs., tables, 11 x 8 in., bound. $4.00.——A record of the latest achievements of the various research committees of the Society. The topics discussed include antifriction bearings, boiler metal failures, Diesel fuel oil, lubrication, management, mechanical springs, metal cutting, metal at high temperatures, thermal properties of steam and wire rope.

These papers have appeared in the *Transactions* of the A. S. M. E. and in *Mechanical Engineering*. They reappear in this volume in convenient form for preservation.

SUR L'UTILISATION DE LA CHALEUR DANS LES MACHINES A FEU. By Henri B. Reitlinger. Paris & Liége, Ch. Béranger, 1930. 254 pp., 10 x 7 in., paper. 60 fr.——An investigation of the complex phenomena involved in the operation of a thermal power plant, undertaken to develop a method by which the conditions for securing maximum efficiency of the plant, as a whole, may be determined. The author first presents the laws governing the thermostatic and thermodynamic transformations in a new form which enables him to obtain a more complete view of the utilization of the heat than can be obtained by the usual methods. He then applies the results of the method to the solution of practical problems and shows how they may be used in the design of power plants of various kinds.

ENGINEERING SOCIETIES LIBRARY

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

ORDER FORM FOR REPRINTS OF FULL PAPERS ABRIDGED IN THIS ISSUE OF *ELECTRICAL ENGINEERING**

(April 1931)* Number	Author	Title
☐ 30-191	E. R. Stauffacher	Development of a Relay Protective System
☐ 31-3	J. B. MacNeill	The Trend in Development of Modern Circuit Interrupters
☐ 31-6	Malcolm Thomson	Resistance Welding of Motor Frames
☐ 31-8	J. W. Milnor	Submarine Cable Telegraphy; Influence of Interference
☐ 31-11	K. B. McEachron and E. J. Wade	Field Tests on Thyrite Lightning Arresters
☐ 31-19	S. R. Bergman	A New System for D-C. Arc Welding
☐ 31-22	H. L. Wills and O. B. Blackwell	Noise-Frequency Induction
☐ 31-23	R. N. Conwell and H. S. Warren	Low-Frequency Induction
☐ 31-35	R. M. Baker	Commutation and Current Collection in Hydrogen
☐ 31-58	A. J. Dreux and H. C. Brunner	A Modern Electrified Dairy Plant

*Members, Enrolled Students and subscribers are entitled to one complete copy of any paper abridged if it is requested within one year from date of its JOURNAL publication. Thereafter a charge of twenty-five cents per complete copy will obtain.

Selected Items *From* Engineering Index Service

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 1,800 technical periodicals are given in the following columns.

All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page or make translations of foreign articles at cost.

Ammeters

HIGH FREQUENCY. Un Ampèremetre pour très hautes fréquences (Ammeter for Very High Frequencies). *Industrie Electrique*, vol. 39, no. 924, Dec. 25, 1930, pp. 558-561, 3 figs. Theory and construction details of hot-wire instrument measuring up to 100 million cycles; performance and correcting calculations are given.

Cables

MANUFACTURE. Aids to Better Cable Production. *Elec. World*, vol. 97, no. 4, Jan. 24, 1931, p. 197, 3 figs. Anaconda Wire & Cable Co. in production of its high-voltage cable is employing lead press specially equipped to maintain uniform thickness of lead sheath, and special facilities for determining power factor, capacity, dielectric loss, breakdown, ionization, and life of cable under cyclic loading; transformers up to 750,000 volts are used for testing.

TESTING. Cable Testing in the Detroit Edison Company, E. J. Manuel. *Elec. Light and Power*, vol. 9, no. 2, Feb. 1931, pp. 30-32, and 34, 5 figs. Cable testing in Detroit Edison Company is done with kenotron which has advantages of light weight and compactness, making it possible to mount testing equipment in truck or trailer and move hurridly to any desired location; set may be operated from either 110- or 220-volt supply; disadvantages to use of high voltage a-c. for testing purposes, are enumerated.

RADIO. Underground Circuits for the Transmission of Broadcast Programmes, A. C. Timmis and C. A. Beer. *Post Office Elec. Engrs., Jl.*, vol. 23, pt. 4, Jan. 1931, pp. 315-321, 4 figs. Essential part of Regional Broadcasting System in England now being constructed is network of land lines or repeater circuits which link up studios in London and elsewhere with radio transmitters, so that program from any studio may be radiated from all or any of transmitters; analysis of main considerations involved in faithful transmission of music under commercial conditions.

TELEGRAPH — FAULT LOCATION. Stoerungsdienst zur Beseitigung von Kabelfehlern unter besonderer Beruecksichtigung der Stoermungsbeseitigung in Verteilungskabeln beim Telegraphenbauamt Berlin, F. Glass. *Telegraphen und Fernsprechtechnik*, vol. 19, no. 12, Dec. 1930, pp. 382-387, 10 figs. System and methods are described.

TELEPHONE. Notable Telephone Developments in 1930. *Telephone Engr.*, vol. 35, no. 1, Jan. 1931, pp. 17-18, 1 fig. World communication during past year has made great strides toward giving all countries daily telephone service with each other, either by direct radio circuits or through land lines from radio terminals.

UNDERGROUND. Some Notes on Underground Cables, E. S. Simkins. *Iron and Steel Engr.*, vol. 8, no. 1, Jan. 1931, pp. 32-34. Factors controlling current carrying capacities with particular regard to properties of various insulating materials; operating temperatures of rubber, varnished cambric and paper insulation; thermal characteristics of duct structure and protection of cables after installation.

Circuit Breakers

Modern Switchgear Developments, F. G. Sublet. *Elec. Times*, vol. 9, nos. 10, 11 and 12, Oct. 27, 1930, pp. 633-636, Nov. 27, pp. 676-678, and Dec. 27, pp. 751-756, 9 figs. Functions of circuit breaker; rupturing capacity tests; oil piston theory for oil circuit breaker; recent experimental developments; electric air; air blast circuit breaker.

OIL. The Distribution of Energy Liberated in an Oil Circuit Breaker; with a Contribution to the Study of the Arc Temperature, C. E. R. Bruce. *Instn. Elec. Engrs.—Advance Paper*, received Dec. 1, 1930, 25 pp., 7 figs. Manner of dissipation of this energy is dealt with in considerable detail for various currents and for 5,500 volts (r. m. s.); energy dissipated at contact surfaces; energy radiated from arc; energy required to heat, vaporize and break up oil; energy used in raising gas to arc temperature and energy used in dissociating hydrogen present.

Condensers

MEASUREMENT. A New Method of Measuring the Capacity of Small Condensers, H. M. Barlow. *Lond., Edinburgh and Dublin Philosophical Mag. and Jl. of Science*, vol. 11, no. 68, Jan. 1931, pp. 184-193, 4 figs. One of best methods is to employ commutator to charge and discharge it with periodicity that can be accurately determined; when dealing with condensers under about 100 micro-microfarads really accurate observations are not then possible; with object of overcoming this difficulty attempt was made to employ two thermionic tubes in place of commutator, charging and discharging of condenser being controlled by alternate positive and negative potentials applied to grids.

Conductors

Temperature Rise of a Conductor due to the Electric Current, Y. Ikeda and K. Yoneta. *Hokkaido Imperial University—Faculty of Eng.—Memoirs*. vol. 2, no. 5, Dec. 1930, pp. 107-145. Mathematical analysis of temperature rise of thin wire and strip with rectangular cross section; results can be applied exactly to problem of fusion of fuse as shown in later paper in same issue; application to design of dimension of galvanometr-string and that of electric heater. (In English).

Control

MACHINE TOOLS. Control of Individually Driven Machine Tools, C. H. S. Tupholme. *Mech. World*, vol. 89, no. 2296, Jan. 2, 1931, pp. 9-10. Maximum output and greatest flexibility of operation are obtained only when motor-driven machine tools are equipped with some form of automatic control; all automatic controlling devices divided into two classes; one known as time acceleration starters, and other as current-limit starters or series relays; complete control from one point is of greatest value for many classes of work, as workman can change speed at will as best suits work as it progresses.

Culture

ENGINEERING. Engineering Culture, H. F. Moore. *Science*, vol. 73, no. 1881, Jan. 16, 1931, pp. 51-54. It is not justifiable in author's opinion to exclude from any system of general culture consideration of viewpoint, either of scientific method, or of viewpoint of applied science; is it not just to call a man uncultured who knows history and philosophy of heat engine, but is ignorant of music, while musician is hailed as cultured, who is master of his technique but contemptuous of science which has made possible modern pipe organ; some positive contributions of engineering to culture are cited. Address before Am. Assn. Advancement Science, Dec. 30, 1930.

Dielectrics

Dielectric Phenomena at High Voltages, B. L. Goodlet, F. S. Edwards and F. R. Perry. *Instn. Elec. Engrs.—Advance Paper*, received Dec. 16, 1930, 33 pp., 32 figs. Breakdown of air, oil and solid dielectrics by normal frequency, impulsive and high frequency voltage; large amount of original numerical data is given, covering entire range of voltage up to one million volts.

Economics

ENGINEERING. Engineering, Economics, and the Problem of Social Well-Being—The Engineer's View, R. E. Flanders. *Mech. Eng.*, vol. 53, no. 2, Feb. 1931, p. 99-104. Social problems presented by business cycle for solution by engineers; more complete science of economics needed; inter-relations of engineering, science and invention; work for coal engineer.

Electric Discharge

The Potential of the Walls in the Cathode Dark Space, J. W. Beck and K. G. Emeleus. *Lond., Edinburgh and Dublin Philosophical Mag. and Jl. of Science*, vol. 11, no. 68, Jan. 1931, pp. 54-64, 8 figs. Method for finding potentials in cathode dark space has recently been developed; which affords test of Morse's theory of dark space and leads to determination of Townsend's ionization for electrons; Brown and Thomson's values for these differ somewhat from Townsend's and it was thought that this might be due in part to effect of wall charges in discharge-tubes used by them; for this and other reasons it seemed of interest to undertake investigation of wall potential described.

Electric Drive

CENTRIFUGES. The Application of Electric Motors to the Driving of Centrifugal Machines. *Engineer*, vol. 151, no. 3915, Jan. 23, 1931, p. 112, 1 fig. Notes based on information supplied by Pott, Cassels and Williamson, of Motherwell, have been confined principally to induction motors which are mainly used in sugar factories and refineries, owing to provision of three-phase supply; when d-c. is used friction clutches are usually interposed between centrifugal and motor.

COMPRESSORS. Two-Speed Synchronous Motors Drive Compressors, H. E. Larson. *Power*, vol. 73, no. 4, Jan. 27, 1931, p. 138-141, 8 figs. Five synchronous-motor torques are considered in application of equipment to reciprocating compressor drives; to allow operating compressors are reduced output two-speed synchronous motor has been developed and machines of that type are now in service.

ROLLING MILLS. Main Roll Drive Statistics.—1930. *Iron and Steel Engr.*, vol. 8, no. 1, Jan. 1931, pp. 34-38. Tabulated lists of main roll drives installed in 1930 in United States and Canada; showing hp., r.p.m., voltage, cycles, type and size of mill, method of drive, date of purchase, name of plant and location.

STEEL PLANTS. Electrical Equipment for Steel Mills, H. A. Winne. *Blast Furnace and Steel Plant*, vol. 19, no. 1, Jan. 1931, p. 109-110. Data on outstanding features of mill drives installed during 1930; reversing mill drive; d-c. main drives; motor driven heavy shears.

Electric Furnace

Recent Trends in Electric Heating, G. M. Bayne. *Elec. News*, vol. 40, no. 3, Feb. 1, 1931, pp. 79-80, 1 fig. New types of highly efficient electric furnaces available for specific requirements indicate that application of electric heat-treating is only on its infancy.

Electric Furnaces: Their Development and Application, V. O. Cutts. *Metal Industry (Lond.)*, vol. 38, no. 3, Jan. 16, 1931, pp. 78-80 and 99-100, 6 figs. Economic considerations; non-ferrous metal and melting furnaces; induction furnaces for melting; adoption of electric heating never results in inferior product; it often renders possible improved product.

ALUMINUM ALLOYS. The Heat Treatment of Aluminum Alloys in the Electric Furnace. *Metal Industry (Lond.)*, vol. 38, no. 3, Jan. 16, 1931, pp. 81-82, 6 figs. Two typical alloys, 17S and 51S, are considered with view to illustrating function of heat treatment; artificial aging.

ANNEALING. Varies Annealing Temperature by Induction Regulator, R. W. Miller. *Steel*, vol. 88, no. 5, Jan. 29, 1931, pp. 38-40, 3 figs. Operation and design of electric annealing furnaces by Brown, Boveri & Co., Ltd., Baden, Switzerland; induction regulator enables voltage to be raised or lowered by 100 per cent from voltage in power line.

DESIGN. Electrothermal Processes, H. Moore. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 409, Jan. 1931, pp. 189-192. Technical advance in electric furnaces has been generally in improvement of detail and increase in size of unit; there is also marked tendency towards simplification of types; most significant advance has been rapid growth of high frequency induction furnace from small units melting few pounds of metal to furnaces melting up to one ton or more of steel in each charge.

ELECTRODE REGULATION. New Magnetic Hydraulic Electrode Regulator for Arc Furnaces, C. C. Loeb. *Iron Age*, vol. 127, no. 5, Jan. 29, 1931, p. 402-405, 3 figs. Sketches illustrate principles and operation of Tagliaferri regulator.

HIGH FREQUENCY. Typical Installations of Coreless Induction Furnaces, E. F. Northrup. *Iron Age*, vol. 127, no. 5, Jan. 29, 1931, pp. 395-399 and 447, 4 figs. Data on modern installations of coreless induction furnace for melting steel; usefulness as refining furnace and as ladle; views as to future of industrial melting. Bibliography.

Power Problems in High-Frequency Melting, E. F. Northrup. *Iron Age*, vol. 127, no. 4,, Jan. 22, 1931, pp. 318-332 and 367-368, 14 figs. Reliability and life of furnace and electric equipment; factors controlling melting efficiency and results obtained from specific installations in superheating gray iron and making different varieties of alloy steel; data on control of stirring effects.

INDUCTION. The Coreless Induction Furnace in a New Role, A. G. Robiette. *Iron and Steel Industry*, vol. 4, no. 4, Jan. 1931, pp. 125-129, 4 figs. Review of possibilities of this furnace as refining appliance; data on furnace linings; carbon removal; dephosphorization; oxidizing with ore while melting; economies of induction steelmaking.

REFRACTORY MATERIALS. Refractory Materials for Electric Furnaces, A. B. Searle. *Metal Industry* (*Lond.*), vol. 38, no. 1, Jan. 2, 1931, pp. 3-4. Melting of lead and its alloys including type of metal, babbitt metal, and solder; temperature considerations; types of brick; shapes of bricks for lining; furnace roof.

Electric Measurements

REACTIVE POWER. Méthode de mesure de l'énergie électrique (Method of Measurement of Electric Energy), N. Koppel. *Industrie Electrique*, vol. 40, no. 925, Jan. 10, 1931, pp. 14-15, 5 figs. Method outlined allows for measurement of reactive power with ordinary calibration watt-hour meter.

Elevators

ELECTRIC. Operating Two Elevator Cars in One Hoistway, H. D. James. *Power*, vol. 73, no. 3, Jan. 20, 1931, pp. 100-103, 8 figs. In first commercial installation of its kind, two cars run on same guide rails, with another set of guide rails for counterweights; each elevator car in office building of Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa., rated at 3,000 lb. at 600 ft. per min.; floor-button system of control and full-automatic operation; design and operating characteristics; plan and elevation views of hoistways.

High-Speed Lifts, R. E. Hopkins. *Elec. Rev.*, vol. 108, no. 2773, Jan. 16, 1931, pp. 95-96, 2 figs. Review of two-speed problem on polyphase supply systems, with special reference to two-speed slip-ring "Equistop" motor.

Fuses

DESIGN. Rechnerische Bestimmung der Strom-Zeit-Kurve und des Grenzstromes; Beitrag zur Frage traeger Sicherungen (Numerical Determination of Current-Time Curve and of Limiting Current; Contribution to Problem of Slow-Acting Fuses), H. Vollhardt. *Elektrotechnische Zeit.*, vol. 52, no. 2, Jan. 8, 1931, pp. 37-40, 6 figs. Simple rule for graphical differentiation of exponential curves developed and correctness mathematically proven.

Mathematical Investigation of the Practical Formula on the Fusion of Fuse, Y. Ikeda and K. Yoneta. *Hokkaido Imperial University—Faculty of Eng.*—Memoirs, vol. 2, no. 5, Dec. 1930, pp. 147-159, 3 figs. Theoretical mathematical analysis. (In English).

Gases

ELECTRIC DISCHARGE. Les particularités de la décharge électrique dans les gaz rares, au point de vue de leur application a l'éclairage (Particularities of Electric Discharge in Rare Gases Considered from Standpoint of their Application in Lighting Practice), M. Laporte. *Revue Générale des Sciences*, vol. 41, no. 19, Oct. 15, 1930, pp. 543-548, 2 figs.; see also *Genie Civil*, vol. 98, no. 4, Jan. 24, 1931, p. 95, 2 figs. Contents of rare gases in air; chemical and electric considerations for use of rare gases; process in purification from lighting standpoint; spectrum of neon is most important because of its richness of red, orange and yellow rays.

Generators

WATER WHEEL. 20,000-Kva. Water Wheel Alternators, S. Neville. *Metropolitan-Vickers Gaz.*, vol. 12, no. 213, Jan. 1931, pp. 286-291, 10 figs. Two machines constructed and installed by Metropolitan Vickers Co., as initial generating plant of Waikaremoana hydroelectric power station of New Zealand have normal rating of 20,000 kva. at 0.8 power factor and are designed to B.E.S.A. specification no. 169 which provides for overload capacity of 25 per cent for two hours they have also 2 hr. rating of 25,000 kva. at 428 r.p.m.

Hoists

CONTROL. Automatic Control of Skip Hoists. *Elec. Times*, nol. 79, no. 2047, Jan. 15, 1931, pp. 119-120, 3 figs. Special features of Brookhirst switchgear equipment; comprising automatic motor starter of solenoid type, contactor type main and reversing switch, overload protective devices and isolating switch for preventing possibility of contact with "live" parts.

Hunting

SYNCHRONOUS MACHINES. Contribution a l'étude des oscillations d'un alternateur ou moteur synchrone (Study of Oscillations of Alternator or Synchronous Motor), F. Margand. *Société Francaise des Electriciens—Bul.*, vol. 10, no. 112, Dec. 1930, pp. 1302-1339, 11 figs. General equations of three-phase machine in variable condition; summary of equations for permanent state; equations for small movements around permanent state, oscillation of synchronous machine with constant excitation, etc.; theoretical mathematical analysis.

Hydroelectric

POWER PLANTS. Load and Plant Factors S. L. Kerr. *Power Plant Eng.*, vol. 35, no. 4, Feb. 15, 1931, pp. 258-260, 4 figs. Influence on operation economy; economic loading of water turbines; seasonal variation and load regulation; test efficiency compared with over-all plant efficiency corrected for gate leakage.

Insulating Materials

PAPER. Uses of Paper in Electrical Apparatus, W. H. Anderson. *Elec. Jl.*, vol. 28, no. 2, Feb. 1931, pp. 99-103, 10 figs. In manufacture of condensers paper is very thin kraft or linen tissue; somewhat heavier paper is now being wound on fine magnet wires in place of customary cotton covering; this application, though new, promises to become extensive; another class of paper generally used throughout electrical industry is for slot cell insulation in motors and generators.

TESTING ELECTRODES. Die Ausbildung von Pruefelektroden nach Rogowski (Defining Form of Rogowski Test Electrodes), C. Stoerk. *Elektrotechnische Zeit.*, vol. 52, no. 2, Jan. 8, 1931, pp. 43-45, 1 fig. For measurements and experiments on insulating materials, form of electrode as proposed by Rogowski is often recommendable; line of reasoning is given by which electrodes can be selected; graph from which form can be deduced.

Insulation

RESEARCH. Still a Long Way to Go in the Study of Insulation, W. P. Dobson. *Elec. News*, vol. 40, no. 3, Feb. 1, 1931, pp. 83-84. Research divided into three classes; first is designated "fundamental research" having as its object discovery of properties and laws of insulation based upon fundamental properties of matter; second, embraces those studies which aim to use fundamental research to build ups empirical formulas applicable to design of insulation; third division, includes practical problems of design, improvement in materials and methods of application.

Lamps

GLOW. A Three-Element Glow Lamp for Sound Recording, V. T. Braman. *Projection Eng.*, vol. 3, no. 1, Jan. 1931, pp. 19-20, 2 figs. Employment of third element in glow lamps overcomes certain difficulties heretofore experienced in sound recording.

ULTRA VIOLET. Ultraviolet Radiation from the Sunlight (Type S-1) Lamp, A. H. Taylor. *Optical Soc. Am.—Jl.*, vol. 21, no. 1, Jan. 1931, pp. 20-29, 6 figs. Sunlight (Type S-1) lamp introduced in fall of 1929 as affording means of dual purpose lighting, combining light for vision and radiation for health maintenance; electrical characteristics; spectral energy characteristics; energy distribution; operating conditions; instruments and methods of measurement; grapical representations of data; effect of blackening of bulb.

Lighting

CODES. Code of Street Lighting. *Illum. Eng. Soc.—Trans.*, vol, 26, no. 1, Jan. 1931, pp. 15-35 and (discussion) 35-38, 1 fig. Code covers status and purposes of street lighting; visibility under street lighting conditions; lighting fundamentals; classification of streets; recommended practise for light traffic, medium traffic, and heavy traffic thoroughfares, business districts, alleys, and highways.

Lines

CONSTRUCTION. Line Construction Organization Methods. *Nat. Elec. Light Assn.—Report*, no. 111, Jan. 1931, 7 pp. Policies of several representative operating companies on various phases of line construction organization and efficiency methods are reviewed; present practise in purchase of hand tools and use of power operated tools in roofing, gaining, and boring poles are analyzed; study of line crew personnel and educational methods.

SWITCHES. Pole-Top Switches Redesigned for All-Wood Construction, F. E. Andrews. *Elec. World*, vol. 97, no. 5, Jan. 31, 1931, p. 226, 2 figs. Following adoption of all wood 33-kv. line construction on system of Public Service Company of Northern Illinois problem arose in design of pole-top switches for use on these lines; with cooperation of several switch manufacturers pole-top switches have been designed in conformity with new line construction. Before Nat. Elec. Light Assn.

GROUND DETECTORS. Neon Tubes Make Inexpensive Ground Detector, H. P. Currin. *Elec. World*, vol. 97, no. 2, Jan. 10, 1931, p. 110, 1 fig. Short sections of neon tubes with porcelain insulators for supplying exciting current proved quite satisfactory in 2,400-volt detector system.

VOLTAGE CONTROL. Voltage Surveys and How They Are Made, E. S. Lincoln. *Indus. Eng.*, vol. 89, no. 1, Jan. 1931, pp. 20-23, 5 figs. Importance of proper voltage maintenance in electrical apparatus; effect of voltage variation in following equipment; d-c. and synchronous motors, heating apparatus, and lighting system; low-voltage and single-phase or three-wires d-c. systems of voltage surveys.

HIGH TENSION — DESIGN. Calcul mécanique des conducteurs et de la tension de pose des lignes a très haute tension (Mechanical Strength Calculation for High-Tension Transmission Lines), H. Roux. *Electricien*, vol. 62, no. 1507, Jan. 1, 1931, pp. 2-6, 5 figs. Equations and curves for calculation of span, sag, stresses, etc.

PROTECTION. Safeguards for Low-Voltage Electrical Supply, H. C. Graves and J. A. C. Krips. *Power Plant Eng.*, vol. 35, no. 3, Feb. 1, 1931, pp. 210-213, 7 figs. Dual power sources, automatic transfer and protected circuit breakers, time limits, convenient inspection and repair; remote control and removable breakers overcome previous limitations.

Lighting

CAR. Electric Train-Lighting Equipment, C. Coppock. *Ry. Engr.*, vol. 52, no. 612, Jan. 1931, pp. 37-40, 8 figs. Design, construction, and operating features of equipment manufactured by J. Stone and Co.; wiring diagrams. (Continuation of serial.)

Loud Speakers

Some Measurements of Loud-Speaker in Vacuo, P. K. Turner. *Instn. Elec. Engrs.—Advance Paper*, Jan. 19, 1931, 20 pp., 18 figs. Electrical impedance of moving-coil loud-speaker is measured with coil held fast with coil free, but in vacuo; under normal conditions; from basic analysis of this type of instrument, which is given briefly, it follows that this series of measurements should allow sufficient separation of its various characteristics to lead to possibility of estimating its actual performance.

Magnetic Units

La question du "gauss" (The Problem of the "Gauss"), C. O. Mailloux. *Revue Générale de l'Electricité*, vol. 29, no. 4, Jan. 24, 1931, pp. 125-132. International Electrical Commission has introduced "Oersted" as C. G. S. unit of electric field in order to end differing conceptions of Gauss unit in United States, Great Britain and other countries; author who has taken active part in 1900 in discussions at American Institute Electrical Engineers and Electricity Congress in Paris, where Gauss unit was accepted, discusses correctness of decision of International Commission.

Measuring Instruments

Electrical Measuring Instruments Other Than Integrating Meters, C. V. Drysdale. *Instn. Elec. Engrs.—Jl.*, vol. 69, no. 409, Jan. 1931, pp. 170-178. Principal items of progress since appearance of last review in June, 1928, have been development of instrument transformers with nickel-iron cores; improvement of soft iron instruments; more general employment of spring supported pivots or jewels; adaption of thermocouples and copper-oxide rectifiers to permanent magnet instruments; introduction of new forms of a-c. potentiometers; application of photoelectric cells to photometry.

Mechanical Stresses

FIXED CONDUCTORS. Phénomènes electrodynamiques dus aux courants intenses dans l'appareillage (Electrodynamic Phenomena Due to Strong Currents in Equipment), C. Bresson. *Revue Générale de l'Electricité*, vol. 29, no. 1, Jan. 3, 1931, pp. 13-30, 24 figs. Summary of basic formulas necessary for calculation of dynamic stresses resulting from conductors in defined positions; development for practical use in design of electric apparatus and equipment as to mechanical strength with respect to short-circuit effects.

Motors

RAILROAD. Le moteur de traction a courant continu en service sour tension ondulée (Direct Current Traction Motors Operating on Pulsating Voltage), K. Toefflinger. *Revue Générale de l'Electricité*, vol. 29, no. 3, Jan. 17, 1931, pp. 105-112, 7 figs. Effect of rectified current on operation of motor can be satisfactory if certain precautions are taken; means to be applied are discussed.

Compound Motors Tested on Two French Systems. *Elec. Ry. Jl.*, vol. 75, no. 2, Feb. 1931, pp. 92-93. System developed by Lievre, of Marseilles, using compound motors with series-parallel control and regeneration, shows savings of 30 per cent from similar equipment with series motors.

SYNCHRONOUS. Simplex Synchronous Motor, M. A. Hyde. *Elec. Jl.*, vol. 28, no. 2, Feb. 1931, pp. 77-80, 6 figs. Simplex synchronous motor delivers both high starting and pull-in torque with low starting current and without use of any mechanical loading device.

Networks

ALTERNATING CURRENT. Design of Secondary Distribution Systems, V. W. Palen. *Power Plant Eng.*, vol. 35, no. 4, Feb. 15, 1931, pp. 264-267, 9 figs. Economic secondary design for single-phase system serving city of about 120,000; design data and calculations. (To be continued.)

CALCULATION BOARDS. The A-C. Calculating Board Simplifies System Design, W. W. Parker. *Elec. Light and Power*, vol. 9, no. 2, Feb. 1931, pp. 28-29, 2 figs. Demand for calculating board which would accurately take into account phase angle considerations in solution of networks for relay applications and for study of voltage regulation, load. control, and stability has been met by Westinghouse Company; equipment is described.

LOAD ANALYSIS. A Few Operating Characteristics of Domestic Motors, Radio Sets and Neon Signs, A. W. Murdock. *Hydro-Electric Power Commission Ont.—Bul.*, vol. 18, no. 1, Jan. 1931, pp. 16-22, 2 figs. Attempt to analyze characteristics from two angles, namely, effect of equipment on distribution system, and effect of irregularities in system on equipment. Before Assn. Mun. Elec. Utilities.

PLANNING. System Planning for Economic Distribution Substations. *Elec. News*, vol. 40, no. 2, Jan. 15, 1931, pp. 45-46. Supplementing "A Master Plan for Sound Growth in System Expansion," previously indexed in Jan. 1, 1931 issue; article covers economic considerations necessary for establishment of new or future distribution substations; no general rules can be applied, but every factor should be allotted its true weight to arrive at best balance. From report of Nat. Elec. Light Assn.

SHORT CIRCUITS. Méthode rapide, semi-expérimentale, pour la détermination du courant de cour-circuit permanens dans un réseau quelconque (Quick Semi-Experimental Method for Determination of Permanent Short-Circuit in Any Kind of Network), G. Crivalleri. *Houille Blanche*, vol. 29, no. 167-168, Nov.-Dec. 1930, pp. 174-179, 2 figs. Method is outlined, curves for calculation are given. (To be continued.)

Oil

ACIDITY. Potentiometric Determination of Acidity in Insulating Oils, R. N. Evans and J. E. Davenport. *Indus. and Eng. Chem.—Analytical Edition*, vol. 3, no. 1, Jan. 15, 1931, pp. 82-85, 7 figs. Estimation of acidity in oils employing alkali blue procedure has been found to give more satisfactory results than A.S.T.M. procedure; in latter method, methyl alcohol should not be substituted for ethyl alcohol; electrometric titrations have been carried out on type organic acids successfully.

Paper Mills

ELECTRIC EQUIPMENT. Installation Electrique de l'Usine de Bellegarde (Ain) de la Société Anonyme des Papeteries Darblay (Electric Installation of Bellegarde Plant of the Darblay Paper Co.), A. Perrin. *Revue d'Electricité et de Mécanique*, no. 14, Nov.-Dec. 1930, pp. 19-25, 9 figs. Supply from substation at 8,000 volt, 50 cycles, transformed over seven 800-kva. transformers to 1,000 volt; drive takes place from induction motors of 240 volt ranging from 120- to 800-hp.; equipment and machinery described and specified.

Photoelectric Cells

Der heutige Stand der Forschung auf dem Gebiete der lichtelektrischen Zellen im besonderen Hinblick auf deren technische Anwendungen (Present Status of Research on Photo Electric Cells with Special Regard to Practical Application), Schroeter. *Metallboerse*, vol. 20, no. 103, Dec. 24, 1930, pp. 2805-2806. Physical fundamentals of internal photo effect, variation of conductivity, external photo effect, separation of electrons from surfaces, photo effect in gases, and variation of charging resistance; for practical application essentially exterior photo effect is of value.

Poles

PRESERVATION. New Treatment for Preserving Poles, F. S. Shinn. *Telephony*, vol. 100, no. 3, Jan. 17, 1931, p. 33. Extensive research work carried on for purpose of developing new wood preservative; zinc meta arsenite (ZMA) found to be most practical. Address before Annual convention, Ill. Telephone Assn.

Potentiometers

GLASS ELECTRODE. The Glass Electrode and Vacuum Tube Potentiometers, D. H. Cameron. *Am. Leather Chemist Assn.—Jl.*, vol. 26, no. 1, Jan. 1931, pp. 7-23. Description, disadvantages and use of glass electrode for pH determinations.

Power Factor

The Power Factor Problem. *Elec. Engr. of Australia and New Zealand*, vol. 7, no. 9, Dec. 15, 1930, pp. 327-328, 1 fig. Savings that can be made by correction; economics of situation.

Power Supply

BUILDINGS. Electric Service for Hotels and Office Buildings. *Nat. Elec. Light Assn.—Report*, no. 112, Jan. 1931, 28 pp., 27 figs. Compiled information on use of electric service to serve as guide for engineers, architects and owners of such buildings or buildings of similar character, in selecting source of electric service; report generalizes on application of purchased electric service and brings out its tangible and intangible advantages.

CAR RETARDERS. New Haven Develops Unique Power Supply for Retarders at Providence Yard, W. F. Follett. *Ry. Signaling*, vol. 89, no. 1, Jan. 1931, pp. 11-12 and 14, 4 figs. Special motor-generator in combination with storage battery reduces power consumption to 30 watts per classified car when yard is being operated at capacity; importance of automatic switching.

Radio

AERIAL TRANSPORTATION. Port and Pilot Communication by Radio Telephone, A. E. Brundage. *Airports*, vol. 6, no. 2, Feb. 1931, pp. 11-13, 3 figs. Advantages of two-way communication between plane and airport, and available equipment; map shows air transport lines equipped with radio telephone.

AMPLIFIERS. Audio Compensated Amplifier for Broadcasting and Recording Studios, J. G. Aceves. *Radio Eng.*, vol. 11, no. 1, Jan. 1931, pp. 37-38, 5 figs. New audio amplifier system which permits of compensating for improper room acoustics and for loudspeaker deficiencies.

BATTERIES. Wireless; The Real Problem, S. T. Wallace. *Telegraph and Telephone Jl.*, vol. 17, no. 190, Jan. 1931, pp. 75-76. Problem of various batteries used in radio receivers; some may consider that all-electric operation is ultimate solution to difficulty, but for present discussion this can be dismissed; it is very long way off for great majority and in many directions it has its own peculiar difficulties, evidenced even in progressively electric America, where battery operated receivers are still very much to fore; there is occasional talk of cold tubes; they are not urgently required; infinitely more pressing problem is abolition of need for high voltages.

CONDENSERS, ELECTROLYTIC. Electrolytic Condensers — Characteristics and Methods of Measurement, W. L. Dunn. *Radio Eng.*, vol. 11, no. 1, Jan. 1931, pp. 31-33, 4 figs. Engineering presentation of true action and performance of electrolytic condensers used in radio receivers.

Characteristics of Dry-Electrolyte Condensers, H. Ross. *Radio Eng.*, vol. 10, no. 12, Dec. 1930, pp. 27-28. Laboratory examination of dry-electrolyte condensers show characteristics for radio receiver operation.

FREQUENCY METERS. Ein einfacher Frequenzmesser hoher Genauigkeit (Simple Frequency Meter of High Degree of Exactness), H. Piesch. *Zeit. fuer Hochfrequenztechnik*, vol. 36, no. 6, Dec. 1930, pp. 211-217, 5 figs. Review of existing types, calibration standards; measuring equipment over wide range of frequency, absorption wave meter, performance, theoretical fundamentals, application of phenomena for measuring purposes, description of measuring arrangement with absorption circuit. Bibliography.

GENERATORS. Motor Generators, Dynamotors, and Rotary Converters for Radio Uses, E. W. Berry. *Radio Eng.*, vol. 10, no. 12, Dec. 1930, pp. 44, and 46, 1 fig. Field for a-c. tube receivers extended by installation of machine converters; types of units are described.

MEASURING INSTRUMENTS. Rectifier Type Instruments, W. N. Goodwin, Jr. *Radio Eng.*, vol. 10, no. 12, Dec. 1930, pp. 34-35, 1 fig. Practical method of measuring alternating currents of low e. m. f.'s; construction; principle of operation; accuracy; temperature errors; frequency errors; errors due to change in current density; wave form errors.

MEASUREMENTS. Common Difficulties in Receiver Measurements, R. P. Glover. *Radio Eng.*, vol. 10, no. 12, Dec. 1930, pp. 42-43, 3 figs. Dissemination of incorrect data on receiver performance causes serious servicing difficulties; method of receiver measurement; characteristics of tubes and need for tubes having average characteristics.

REMOTE CONTROL. Mechanical Remote Tuning Controls for Radio Receivers, J. C. Smack. *Radio Eng.*, vol. 11, no. 1, Jan. 1931, pp. 28-30, 5 figs. Method of solving problem of remote tuning control for broadcast and airplane radio receivers is outlined.

SHORT WAVE. Short-Wave Receiver Design, A. Binneweg, Jr. *Radio Eng.*, vol. 11, no. 1, Jan. 1931, pp. 26-27, and 30, 3 figs. Regenerative detector short-wave receiver design with experimental results, are considered; with slight change in circuit constants, operation is greatly improved.

SHORT WAVE. A Superheterodyne Receiver for Short Waves, R. W. Tanner. *Radio Eng.*, vol. 11, no. 1, Jan. 1931, pp. 22-23, 1 fig. Oscillator tuned system for high frequency radio reception, giving stable operation is described.

Railroad

ELECTRIFICATION. Railroad Electrification Brings Economies, H. L. Andrews. *Elec-World*, vol. 97, no. 3, Jan. 17, 1931, pp. 153-155, 3 figs. Pennsylvania and Reading, using 11,000 volt, 25 cycle a-c. system are outstanding for fact that initial suburban electrifications is integral part of extensive project in main line electrification; Delaware, Lackawanna & Western is initial suburban project in this country to utilize 3,000-volt d-c. system for multiple unit cars and is first steam railroad operation of any magnitude in world to rely entirely on 3,000-volt mercury arc rectifiers as conversion units; curves and tables showing economy of operation. Presented before New York Railroad Club.

SIGNALS — CENTRAL CONTROL. Results of Centralized Control on N.Y.C., J. J. Brinkworth. *Ry. Signaling*, vol. 24, no. 2, Feb. 1931, p. 52. Review of improvements in train operation effected by centralized traffic control system. Before New England Railroad Club.

SIGNALS—INTERLOCKING. Canadian Pacific Utilizes Modern Interlocking to Protect Movable Bridge, E. S. Taylor. *Ry. Signaling*, vol. 24, no. 1, Jan. 1931, pp. 24-25, 7 figs. Design and operating features of signals and signaling system employed between Sault Ste. Marie, Ont., and Sault Ste. Marie, Mich.; two-lever table interlocking machine controls bridges.

TRAIN CONTROL. Annual Report of Bureau of Safety on Signals and Train Control. *Ry. Signaling*, vol. 24, no. 1, Jan. 1931, pp. 21-23. Abstract of report by Bureau of Safety of Interstate Commerce Commission for fiscal year ending June 30, 1930; special investigations; accidents in train-control territory.

Rectifier

VACUUM TUBES. Ein gasgefuellter Kleingleichrichter mit Oxydgluehkathode (Gas-filled Small Capacity Rectifiers with Oxide Coated Incandescent Filament), M. Knoll. *Elektrotechnische Zeit.*, vol. 52, no. 3, Jan. 15, 1931, pp. 65-68, 8 figs. New types of full-wave rectifier tubes with oxide filament and argon filling of which small dimensions provide for inexpensive manufacture and long life; oscillographic testing.

Refrigeration

ELECTRIC MOTORS. The Patent Situation in Enclosed Motor Refrigeration, H. R. Van Deventer. *Refrig. Eng.*, vol. 21, no. 1, Jan. 1931, pp. 29-32, 18 figs. Term "enclosed motor" as applied to refrigerating machines has been commonly applied to unitary motors and compressors enclosed in hermetically sealed chamber; advantages and disadvantages of arrangement; résumé of patent situation.

Rotors

Coil Support Insulation for Rotor Banding, A. C. Roe. *Indus. Eng.*, vol. 89, no. 1, Jan. 1931, pp. 33-35, 9 figs. Practical discussion of coil supports, materials and methods used to prepare them to receive winding and retaining bands.

Signals

MINES. Underground Signaling with A-C. Circuits, G. Allsop. *Colliery Guardian*, vol. 142, no. 3657, Jan. 30, 1931, pp. 393-394, 2 figs.; see also *Iron and Coal Trades Rev.*, vol. 122, no. 3283, Jan. 30, 1931, p. 217, 2 figs. Suggested methods for signaling, to guard against open sparking; necessity of closing and opening bell circuit has been eliminated by employing choke-coil to vary current through system. Abstract of paper read before Midland Inst. Min. Engrs.

Spark Gaps

CALIBRATION. Sphere-Gap Calibration, S. Whitehead and A. P. Castellain. *Instn. Elec. Engrs.—Advance Paper*, received July 22, 1930, 24 pp., 24 figs. Experiments carried out at East London College upon spark over between spheres and standardization of sphere-gap as voltmeter; origin and objects of research; methods employed in measuring high voltages.

Substations

INDUSTRIAL. Substation Standardized for Small Industrials. *Elec. World*, vol. 97, no. 2, Jan. 10, p. 103, 1 fig. Typical of equipment and arrangement adopted for loop tie-in substations for relatively small industrial customers is 22-kv. Stubenville coal and mining station of Ohio Power Company; airbreak switches are installed on line sides of tap connections leading to transformers and protective equipment, and switches of this type also are interposed in advance of delta-connected transformers; station surrounded by protective industrial wire fence is used for capacities up to 1,000 kva.

REMOTE CONTROL. Midworth Distant Repeater Equipment for Electric Substation Control. *Ry. Gaz.*, vol. 54, no. 1, Jan. 2, 1931, pp. 19-20, 1 fig. System installed on Manchester, South Junction and Altrincham Railway, enabling complete control of Timperley substation maintained from Old Trafford main substation; diagram showing general arrangement of Midworth distant repeater installation; system operation.

Telephone

AUTOMATIC. Problems in Automatic Trunking—Last Contact Traffic, N. A. Hawkins *Post Office Elec. Engrs. Jl.*, vol. 23, pt. 4, Jan. 1931, pp. 272-281, 5 figs. Theoretical considerations of case of full availability and of case of grading; practical applications with examples.

CARRIER CURRENT. Full Description of Type C Carrier System, F. J. Dommerque. *Telephone Engr.*, vol. 35, no. 1, Jan. 1931, pp. 22-24, 5 figs. System accommodates three carrier channels in addition to voice current channel.

ECHO SUPPRESSORS. The New Standard Echo Suppressor, W. F. Marriage, P. R. Thomas and K. G. Hodgson. *Elec. Communication*, vol. 9, no. 3, Jan. 1931, pp. 196-202, 9 figs. International Telephone and Telegraph Laboratories have developed new type of valve echo suppressor which has been standardized by International Standard Electric Corp. and which operates entirely without moving parts and is therefore very reliable and easy to maintain.

PERFORMANCE. Rating the Transmission Performance of Telephone Circuits, W. H. Martin. *Bell System Tech. Jl.*, vol. 10, no. 1, Jan. 1931, pp. 116-131, 1 fig. Rating is discussed on basis of rate of repetitions in telephone conversations; rating method set up on this basis is being adopted in Bell System for determining and expressing data for transmission design of telephone plant.

REPEATERS. Step-by-Step Pulse Repeater P. T. Slattery. *Bell Laboratories Rec.*, vol. 9, no. 5, Jan. 1931, pp. 238-240, 3 figs. Necessity to provide some means of relaying dial, pulses at originating office is met by use of apparatus capable of receiving pulses from subscriber's dial and sending out new ones which will successfully operate switches in distant office, known as pulse repeater; various pulse repeating circuits.

Television

Progress in Two-Way Television, H. E. Ives. *Bell Laboratories Rec.*, vol. 9, no. 6, Feb. 1931, pp. 262-264, 4 figs. Optical features, which make received image quite appreciably more life-like than it appeared with any of earlier apparatus.

MULTI-CHANNEL. A Multi-Channel Television Apparatus, H. E. Ives. *Optical Soc. Am.—Jl.*, vol. 21, no. 1, Jan. 1931, pp. 8-19, 5 figs. Method developed provides image of many-fold mor image elements than heretofore, and may make easier problem of transmission over practical transmission lines; three-channel apparatus; three-electrode neon lamp used; discussion of results.

SYNCHRONIZATION. Die Synchronisierung von Fernsehempfangs-Apparaten, Insbesondere bei Verwendung der Braunschen Roehre (Synchronization of Television Receiving Apparatus with Special Regard to Application of Braun's Tube), E. Hudec. *Fernsehen*, vol. 2, no. 1, Jan. 1931, pp. 14-28, 15 figs. It is shown that perfect synchronism between image-composing and image-dissecting equipment only then is possible, when special synchronizing current is generated at receiver which is completely separated from image current.

Testing Apparatus

High-Voltage Testing Equipments, E. T. Norris and F. W. Taylor. *Instn. Elec. Engrs.—Advance Paper*, received Dec. 16, 1930, 22 pp., 26 figs. Paper describes numerous classes of apparatus available for production of high voltages for testing and experimental purposes and discussed installation and operation of complete testing equipments for various specialized requirements.

Trackless Trolleys

Trolley Bus Costs and Advantages Compared With Other Vehicles, E. H. Lamberger. *Elec. Traction*, vol. 27, no. 1, Jan. 1931, pp. 28-31, 4 figs. Advantages and disadvantages of electric, gas-electric and gas-mechanical buses; curves indicating acceleration characteristics of three types of buses; relative schedule speed characteristics of three types of buses, average engine speed of gas-electric and gas-mechanical vehicles, and power costs; table of comparative investment and operating data between trolley bus, gas-electric and mechanical vehicles.

Trolley Bus Experiences Unprecedented Growth During Past Year, C. A. Faust. *Elec. Ry. Jl.*, vol. 75, no. 1, Jan. 1931, pp. 45-48, 5 figs. Five new installations add 105 vehicles and 34.90 route mi.; with additions of 11 trolleys buses and 7.36 mi. by systems already in operation totals for industry rise to 182 vehicles and 70.05 mi.; present trolley-bus operations in United States and its possessions; table of trolley buses ordered by electric railways during 1930, totaling 116.

Transformers

DESIGN. Transformer Design, E. T. Norris. *Elec. Rev.*, vol. 108, nos. 2774 and 2775, Jan. 23, 1931, pp. 140-142 and Jan. 30, pp. 182-184, 8 figs. Jan. 23: Investigation into methods of reducing stresses in windings resulting from high-voltage surges and steep-fronted traveling waves; initial distribution of surges; results of voltage oscillation; limitation of local stresses; electrostatic shields; maximum wave-length of surges. Jan. 20: Protection of windings against surges by means of external apparatus which reduces steepness of traveling waves.

DISTRIBUTION. Distribution Transformers, E. T. Norris. *Elecn.*, vol. 106, no. 2748, Jan. 30, 1931, pp. 162-163, 4 figs. Effect of lightning surges and line insulation on reliability test; location of failures.

GROUNDING. Buried Copper Grid Affords Uniform Ground. *Elec. World*, vol. 97, no. 6, Feb. 7, 1931, p. 286, 5 figs. System used to obtain fairly consistent ground current behavior by Oklahoma Gas & Electric Company.

RELAYS. Theory and Application of Relay Systems—Transformer Protection, P. H. Robinson and I. T. Monseth. *Elec. Jl.*, vol. 28, no. 2, Feb. 1931, pp. 111-116, 21 figs. In applying differential relays to transformers, ratio differential type rather than ordinary overload type of relay should be used; this results in form of protection which is sensitive to internal faults yet insensitive to short-circuit currents flowing through transformer and caused by external fault conditions.

TAP CHANGERS. Transformers Tap Changing on Load. *Engineer*, vol. 151, no. 3913, Jan. 9, 1931, pp. 58-59, 7 figs. New B. T. H. inexpensive and simple equipment, developed for use with transformers carrying but small current per phase, which at present can be used on transformers up to 6,000-kva. capacity and working on 33,000-volt systems, consists essentially of oil-immersed drum controller, fingers of which make contact on their segments in correct sequence as drum revolves.

Vacuum Tubes

TELEPHONE. Vacuum Tube Theory and Practise as Applied to the Telephone Circuit. *Telephone Engr.*, vol. 35, no. 1, Jan. 1931, pp. 36-38, 8 figs. Types; theory of operation; characteristic curves; constants; plate resistance; mutual conductance.

THYRATRON. Motor Control by Thyratron Tubes, A. G. Turnbull. *Elec. News*, vol. 40, no. 2, Jan. 15, 1931, pp. 64-65, 4 figs. Two examples, illustrating accurate control, point to no limit in application.

Voltmeters

NEON TUBE. The Construction and Operation of a Simple Neon-Tube High-Tension Crest Voltmeter, L. E. Ryall. *Instn. Elec. Engrs.—Advance Paper*, received July 4, 1930, 7 pp., 8 figs. Principles governing design of neon tube crest voltmeter; precautions necessary to secure reliable operation including selection of permanent neon lamp; 150-kv. (max.) crest voltmeter; and design of voltmeters for higher voltages.

Watt-Hour Meters

MAXIMUM LOAD. Hoechstleistungsmesser und ihre Messgenauigkeit (Maximum Load Meters and Their Exactness in Measuring), F. Bergtold. *Elektrische Betrieb*, vol. 29, no. 1, Jan. 15, 1931, pp. 1-5, 10 figs. Determination of maximum required load by means of watt-hour meter with special recording mechanism, performance of this equipment and possible errors in operation.

TESTING. Permanence of Rotating Standard Accuracy, G. E. Meredith *Elec. World*, vol. 97, no. 4, Jan. 24, 1931, p. 188, 1 fig. Out of 212 weekly tests on rotating standard purchased in 1924 by Kansas City Power & Light Co. and in continuous use since that year only 25 show accuracies "as found" above 100.5 or below 99.5 per cent. Before Nat. Elec. Light Assn.

Welding

BRIDGE CONSTRUCTION. Welding in Bridge Work. *Ry. Eng. and Maintenance*, vol. 27, no. 1, Jan. 1931, pp. 42-43, 1 fig. Bridge and Building Assn. considers application of electric welding steel structures; presentation of paper, strengthening a Bridge by Arc Welding Process, by W. R. Roof, and discussion.

CAST IRON. Pure-Iron Electrodes for Welding Cast Iron, H. D. Lloyd and J. S. G. Primrose. *Foundry Trade Jl.*, vol. 44, no. 752, Jan. 15, 1931, pp. 37-38. Effect of phosphide eutectic; mechanical strength of welds; burning-on; thermit process; metallic-arc method; soft-iron rods; welding gas-engine bedplate; fluxes used; danger zones; welding malleable castings. Abstract of paper read before Instn. Welding Engrs.

NICKEL STEEL. Abstract of Thesis on Arc Welding of Nickel Steel, T. K. McManus. *Am. Welding Soc.—Jl.*, vol. 10, no. 1, Jan. 1931, pp. 16-19, 5 figs. Welds in 3½ per cent nickel steel with commercial, chrome-nickel, aluminum-bronze, nickel-steel and chrome-molybdenum wire; tension, bend, impact and fatigue test of original and welded materials supplemented by *H*-ray examination; microphotographs illustrate crystal structure of welds.

PRESSURE VESSELS. Unfired Pressure Vessels, W. Spraragan. *Indus. and Eng. Chem.*, vol. 23, no. 2, Feb. 1931, pp. 220-226, 8 figs. Fundamental factors considered are: (1) selection of material of good welding quality and use of good welding wire; (2) correct design of vessel and welded joints; (3) use of qualified welders; (4) proper preparation of material for welding (5) employment of proper technic; and (6) testing of completed vessel.

Welding Machines

Resistance Butt Welding of Tools. *Welding Engr.*, vol. 16, no. 1, Jan. 1931, pp. 41-42, 5 figs. Design and performance of machines suited particularly for welding of drills and other precision tools.

AUTOMATIC. Automatic Arc Welding. *Engineer*, vol. 151, no. 3915, Jan. 23, 1931, p. 100, 5 figs. A. E. G. system of automatic arc welding was developed to improve upon welding by hand, which presents several well-known disadvantages; automatic machine can weld with higher current values and at greater speeds, while arc can be moved over work uniformly and be made to deposit metal smoothly and continuously; examples of A.E.G. welding machines and their application.

Industrial Notes

H. W. Clough Promoted.—The Belden Manufacturing Company, Chicago, announces the appointment of H. W. Clough as sales manager. Mr. Clough has been with the company for nine years and was previously manager of the Merchandise Division.

Joins Norma-Hoffmann Sales Force.—John W. Blackford, for the past 8 years with the Torrington Company and for the last two years manager of the Detroit office of the above company, has joined the sales organization of Norma-Hoffmann Bearings Corporation, Stamford, Conn.

Rockbestos Products Corporation, New Haven, Conn., manufacturers of electrical wires and cables for use under severe conditions, announces the appointment of Malcolm T. Ritchie as New England territory salesman; the addition to its Pittsburgh sales office of Carleton W. Fletcher, formerly of the main office, and the addition of Philip O. Weston to the home office sales promotion staff.

The General Electric Company, Schenectady, N. Y., has disposed of its trolley line material business to the Ohio Brass Company of Mansfield, Ohio. This includes overhead materials for electric railways, electrified mines, industrial haulage, and electrified steam roads,—a field in which the Ohio Brass Company has specialized quite intensively for many years. This transaction is relatively of small importance because of the volume of business involved, and although of some advantage to both companies, it is principally of benefit to the users of this class of material.

The Daven Company, successors to The Daven Radio Corporation, manufacturers of Super-Davohm wire wound precision resistors, 158-160 Summit Street, Newark, New Jersey, announces the purchase of the Superior Resistor Corporation recently located at 334 Badger Avenue, Newark. The entire equipment of the former Superior Resistor Corporation has been moved and assembled at the Daven plant. With this addition in machinery and equipment The Daven Company has increased its production capacity over 25 per cent. The Daven Company will retain the trade name "Super-Ohm" in addition to their present trade names "Super-Davohm" and "Davohm."

General Electric Annual Report.—Despite the general depression in business, General Electric had a fairly successful year in 1930, with earnings greatest in the history of the company, except for 1929, Gerard Swope, president, disclosed in the annual report of the company recently made public.

Orders received during 1930 amounted to $341,820,312, compared with $445,802,519 in 1929, a decrease of 23 per cent, and unfilled orders at the end of the year totalled $56,062,000, compared with $94,623,000 at the close of 1929, a decrease of 41 per cent. Sales billed for 1930 were $376,167,428, compared with $415,338,094 in 1929, a decrease of 9½ per cent. Net income from sales in 1930 amounted to $40,450,261, which, compared with $49,395,896 in 1929, shows a decrease of 18 per cent. These figures for 1930 do not include radio set and tube business, which was transferred to the Radio Corporation of America on January 1, 1930, except that derived from General Electric radios, which were introduced the latter part of the year.

The average number of employees during 1930, not including those of associated companies, was 78,380, compared with 87,933 in 1929. The total earnings of these employees were $140,905,000 and $163,090,000, and average annual earnings were $1,798 and $1,855 respectively.

Recent Westinghouse Orders.—As a part of the electrical equipment for one of the largest electro metallurgical plants in the world, the Westinghouse Electric & Manufacturing Company has received from the Electro Metallurgical Company, an order amounting to approximately $100,000 for six 5,000 kva. transformers to supply power to electric furnaces. The new plant, which will be at Boncar, West Virginia, is being constructed by the Electro Metallurgical Company, a subsidiary of the Union Carbide & Carbon Corporation.

Other recent orders include the electrical equipment for five 400-hp. gas electric cars to be used on the Santa Fe Railroad. These cars will be duplicates of four others ordered by the same company in 1929. The Westinghouse Electric International Company has been awarded a contract for twelve circuit breakers by Ryobi Denki Shokai, of Japan, for use in the Tokyo district.

An order in excess of $500,000 has been received from the Navy Department for the main propelling machinery and engine room auxiliaries for a new 10,000-ton Treaty cruiser. The new vessel, designated as No. 38, is yet unnamed and will be built at the Mare Island Yard, California. Her four main geared-turbines will deliver a shaft horsepower of 107,000, giving the vessel a speed of 33 knots. The electrical equipment will be a duplicate of that ordered for cruisers 37, 34, and 36, all being for Westinghouse machinery.

The Brooklyn Edison Company has ordered sixteen 1,000-hp. electric motors to be installed in the Hudson Avenue Generating Station as a part of the auxiliary equipment for units in that station.

OF PARTICULAR interest in this month's news are the complete program outline for the annual Summer convention to be held in Asheville, N. C. in June (*pp. 368-371*); a review of the discussion which transpired at the recent district meeting in Pittsburgh (*pp. 372-3*); notice of an economic conference to be held in August at the engineering camp of Stevens Institute of Technology (*p. 373*), and a report upon living conditions in Russia. (*pp. 374-5.*)

B. F. BAILEY, besides having been professor of electrical engineering at the University of Michigan for the past eighteen years, has been a director and consulting engineer for several electrical manufacturers; also an expert patent case witness. He is the author of many books and articles on technical subjects; in this issue he describes some of the noise abatement work carried on at the University under his direction and introduces a symposium on the importance of noise reduction in electrical machinery. (*See p. 340.*)

THE NOISE PROBLEM is broadly treated in six other articles by four engineers of the Bell Telephone System, five of the Westinghouse Company, three of the General Electric Company, and one of the Commonwealth Edison Company, Chicago; each contributes the results of experience gained in his own particular field. (*See pp. 342-352.*)

J. W. MILNOR, for the past twelve years research engineer for Western Union Telegraph Company, and one of the foremost telegraph engineers in the entire world, gives some of the features of design and operation in connection with the New York-Azores high-speed submarine telegraph cable installed in 1928 and ever since then in successful duplex operation. G. A. Randall of the same company assisted Mr. Milnor in preparing this article. (*See p. 337.*)

INDUSTRIAL-UTILITY interconnection problems, one of the subjects to which an entire session was devoted at the recent district meeting at Pittsburgh, are discussed, and advantages accruing to both systems from a free interchange of power interestingly pointed out, by W. B. Skinkle of the Subsidiary Companies, U. S. Steel Corporation. (*See p. 365.*)

Stroboscopic Moving Pictures

By means of moving pictures taken stroboscopically it is possible to see the rotor of a synchronous machine just as though one were actually revolving at synchronous speed with the rotating field of the stator windings. Newly developed thyratron tubes provide sufficient light for taking the pictures.

By H. E. Edgerton

Associate A. I. E. E.

Massachusetts Institute of Technology
Cambridge

OF THE SEVERAL different methods of determining the very important, but rarely measured angular displacement of a synchronous machine, stroboscopic observation is the most direct and straightforward. This method requires a minimum of apparatus; namely, a disk rigidly attached to the shaft of the synchronous machine, a suitable stationary scale for recording the displacement, and an intermittent light source operating in time phase with the terminal voltage of the machine. The disadvantage of the stroboscopic method in the past has been that the measurements had to be recorded visually, and thus the accurate measurement of transient variations of angle has been practically impossible because of the inability of an observer to record the phenomena during the short duration of most transients.

With the stroboscopic device described in this article, enough light is produced so that a motion-picture record can be made of the angular displacement of a synchronous machine. A mercury vapor arc is used which produces the characteristic blue light well known for its powerful actinic properties. The tube used to produce the arc is a thryatron containing grids that control the electrical transients which are the source of the stroboscopic light.

Stroboscopic moving picture records will provide important observations for those who are concerned with the operation of synchronous machines. These moving pictures will be especially valuable when correlated with oscillograms taken simultaneously. The "strobograms," as these pictures may be called, will furnish power engineers with information regarding the angular displacements of their generators, condensers, and lines during switching and short-circuit disturbances. They will tell the users and designers of synchronous motors exactly how far the rotors swing, their period of motion, and the damping of their oscillations for violent, sudden load changes such as are common in the steel industry. Photographic records will be valuable also in studying the steady-state time-angle variations.

In addition this method of photographing stroboscopically illuminated objects will provide research workers with the means whereby many experimental investigations may be made. It is especially adapted for studying the motion of mechanical objects such as springs, cams, valves, and other devices.

Among the important requirements for a stroboscope suitable for photographic purposes, are:

1. Short duration of the light. If the illumination extends over an appreciable period of time the image will be blurred. A rough calculation shows that the duration of the main flash should not be longer than about 10 microseconds.

2. Rich actinic light. Photographic film is much more sensitive to ultra-violet and blue light than to red. For this reason a mercury discharge tube is used in place of the commonly used neon tube. The light from a mercury arc is composed of strong blue and ultra-violet colors. Some of the ultra-violet radiations are, however, absorbed by the glass walls of the tube.

3. Reliability of light-flash control. A synchronously rotating object viewed by a stroboscope will not be stationary if there is any variation in the interval of time between discharges in the stroboscope circuit. This time interval can be controlled very accurately by applying sufficient voltage to the thyratron grid.

THYRATRON CIRCUIT

An arrangement of apparatus capable of producing a powerful stroboscopic light is shown in Fig. 1. Current waves for various branches of the circuit are included also in this illustration. Light is obtained from a condenser discharge through the thyratron tube; and since the only impedance in the circuit besides the thyratron is that of the leads connecting the tube to the condenser this discharge is very rapid, lasting only about 10 microseconds or even less. An intense momentary light flash is thus obtained.

The sequence of events through a cycle of operation will be described in detail. When the grid is negative no current is flowing from the main anode because the grid has the property of extinguishing the arc. Such grid action is contrary to the usually explained rules of thyratron operation but occurs here because of the low density of the anode current and the large condenser in parallel with the arc. During this half cycle, current flows from the 500-volt d-c. source through the resistance into the condenser in the well-known exponential relationship. The resistance and capacity are adjusted so that the potential across the condenser becomes practically 500 volts during the half cycle that the grid is negative. Replacing the resistance *R* with inductance *L*, or using both in series with the condenser, will give a still higher voltage across the condenser, if *R*, *L*, and *C* have proper values.

At the end of the charging half cycle, the grid becomes sufficiently positive to allow current to flow from the anode. The charge that has been accumulated in the condenser will then be discharged through the tube. If short, heavy-stranded leads are used to connect the condenser to the tube the holding arc may be extinguished at this time by the condenser discharge, but this difficulty may be overcome by introducing a choke coil into the holding circuit and a small resistance in series with the condenser. From a recent study by Krug, (of the arc striking speed of a mercury arc rectifier), (*Arch. f. Techn. Physik 11*, 1930, 6 p. 227, and *E. u. M.* 48, June 8, 1930, p. 567), it is known that only 0.01 to 0.1 microsecond is required to start the arc. Thus the thyratron acts virtually as a short circuit across the condenser.

For the remainder of the half cycle following the condenser discharge the grid is positive and the main anode carries a current which is limited in value by the resistance *R*. The light from this current is not intense and is negligible in comparison with the condenser flash. With the pool-type of thyratron this current is oscillatory under some conditions, giving faint ghosts trailing behind the main discharge. A negative bias and a peaked a-c. voltage on the grid eliminates these oscillations.

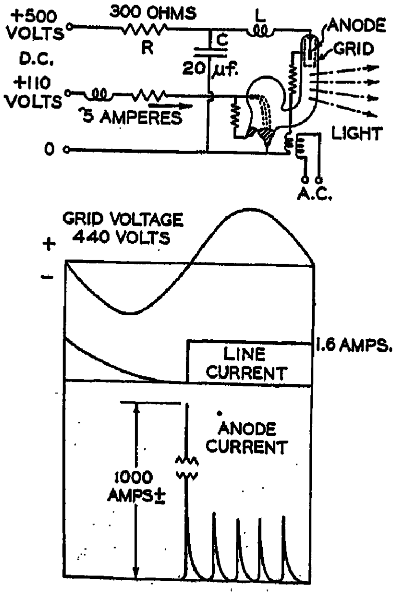

Fig. 1. Schematic diagram of thyratron circuit; voltage and current relations in various parts of the circuit are shown below

At the completion of the operating cycle the grid again becomes negative thereby extinguishing the anode current. The condenser then begins to accumulate a charge for the next flash.

STROBOGRAMS TAKEN

With the thyratron and other apparatus just described, a 160-hp. synchronous motor was photographed stroboscopically as it pulled into step. The tube was hung on a framework so that its light would fall directly upon the field structure. White cardboard collars were tied around the poles and alternately marked "*N*" and "*S*." The amortisseur rings were painted white and the protruding bars black. A general view of the arrangement in operation is shown in Fig. 2.

Strobograms taken during the transfer from operation on half voltage, which was used for starting the motor, to full voltage, are shown in Fig. 3. These consist of a sequence of enlarged, 16-mm. moving picture frames and were taken on panchromatic film at 16 frames per sec. with a lens opening of f-1.9.

The particular thyratron used for these tests had two anodes, each was connected to a circuit such as shown in Fig. 1 but the grids were supplied from a common transformer. No apparent difference in the time of discharge was experienced, except when the tube was cold.

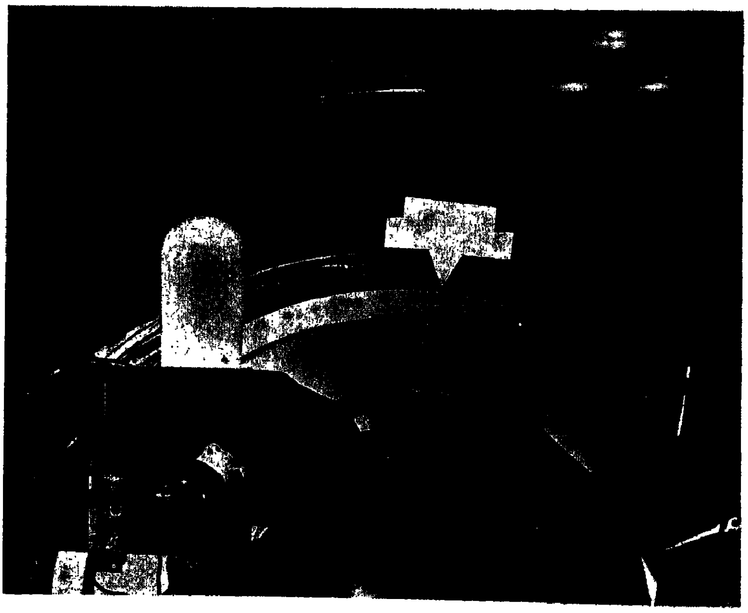

Fig. 2. Thyratron arranged for taking stroboscopic movies of a 160-hp. synchronous motor

A special camera which would record the rotor displacement angle for each cycle could easily be made. This camera would require no shutter and no mechanical framing movement. The film could be run through the camera at a constant speed and just fast enough so that the exposures would be spaced correctly.

A simultaneous reading of time could also be taken with the angle on the strobograms by photographing a clock hand driven by a telechron clock motor running at one revolution per second. This would be quite necessary for accurate testing since there is no definite relation between the frequency of the camera shutter and that of the intermittent light.

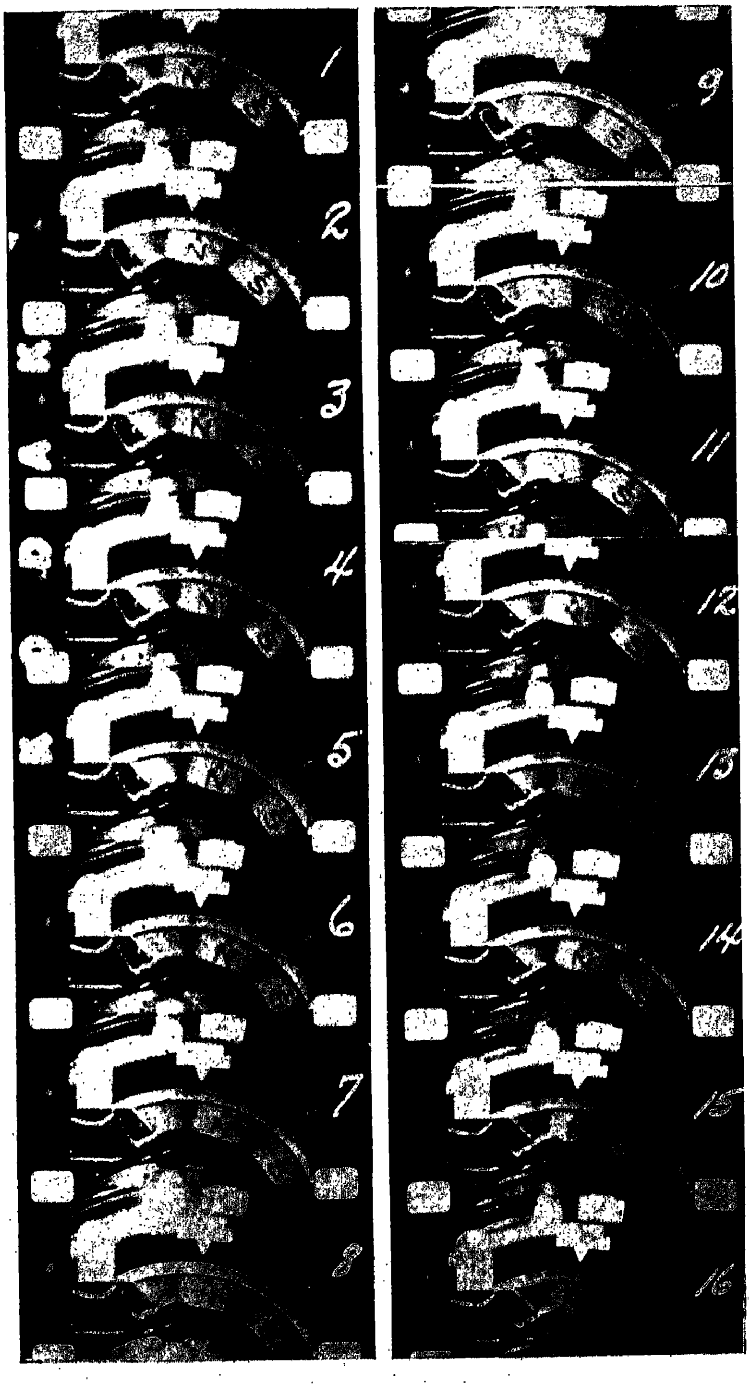

Fig. 3. "Strobograms" of a synchronous motor as it was switched from half to full voltage. Increased angular displacement may be noted as the supply switch was momentarily open during changeover (4-7)

D-C. Power for Industrial Plants

Many large industrial plants depending upon d-c. power for machinery and process operation can ill afford to continue to overlook the economies of modern a-c.—d-c. conversion apparatus and decentralized d-c. supply.

IN THESE DAYS of 200,000-kva. turbine-generators, 90,000-kva. transformer banks, 220-kv. transmission lines, and the many other spectacular achievements in the electric power field, it is only natural that there has been acquired the habit of picturing the electrical industry almost entirely in terms of alternating current. It is a common failing to overlook the fact that hundreds of thousands of less spectacular devices go quietly and unobtrusively about the business of consuming at least one-quarter and probably one-third of the total production of electric energy in the form of direct current. Dominance of the polyphase a-c. system rests on the very solid foundation of fundamental economy and flexibility in generation, transmission, and distribution, together with the sturdy simplicity of the induction motor. However, direct current retains a prominent and apparently permanent place in the field of utilization because of its necessity in electrolytic work and because the flexibility of speed control inherent in the d-c. motor is of such great value in many applications. To realize these advantages of both a-c. generation and d-c. utilization it is necessary to pay the price of providing and operating a system of power conversion and low-voltage d-c. distribution. Thus an intermediate system, an additional overhead, is imposed by these differing methods of production and consumption of electrical energy.

Now in this, as in any case, the ultimate problem of the engineer is to reduce the over-all cost to a minimum consistent with adequate and reliable service. In many systems there is need for service improvement as well as cost reduction. Experience has shown that in the field of power conversion and d-c. distribution, both results can be realized by essentially the same means and methods. Much time and effort expended over a

Fig. 1. Plan of Edgar Thomson works of the Carnegie Steel Company, Pittsburgh, showing d-c. power system

period of years has brought the apparatus for such a system to a high state of development; however, it probably has not been fully appreciated that the economy and improved operation which this modern equipment make possible can be realized fully only through careful planning and proper coordination of the whole system. It is the purpose of this article to bring to the attention of the industry the benefits to be derived through modernization, to state the problem and outline the procedure of system study, to point out the major engineering and economic considerations involved, and to illustrate by describing the evolution and present arrangement of a typical large system.

In the early days of the electrification of industry d-c. power was supplied to a large extent by low-speed engine-driven d-c. generators. Even today many of these elephantine machines are in regular operation, consuming a large amount of energy in the form of losses, requiring a large force of men for operation and maintenance, and taking up an excessive amount of more or less valuable space. In such cases marked economy usually can be effected by changing over to a-c. power supply and modern, high-speed efficient conversion equipment. In certain cases where process steam otherwise would be wasted, high-speed turbine-driven d-c. generators can be used to advantage.

The development of reliable and efficient conversion equipment was an important step forward, but for many years constant operating attendance was necessary at each substation because only manually-operated switching equipment was available. As a result of many large industrial plants having grown up under the limitations imposed by engine-driven d-c. generating equipment and manually-operated conversion equipment, it is not uncommon to find the total d-c. capacity concentrated into one or two large stations, although a large part of the d-c. power must be used at remote parts of the plant. Such an arrangement probably represented good economic practise at the time it was installed; however, a study will show usually that growth of the plant and the development of new apparatus have effected a marked change, and that the present-day result is a rather costly compromise between high distribution loss, low voltage at the load, and an excessive amount of distribution copper.

With the advent of completely automatic and unattended operation of conversion units it became economically feasible to distribute the d-c. substation capacity throughout the system. The average d-c. feeding distance thus is greatly reduced with a corresponding decrease in distribution cost. The saving can be taken in the form of less copper, reduced losses, or both. If improvement in voltage at the load is necessary the advantage gained can readily be turned to that purpose. It is of course necessary in any case to transmit approximately the same amount of power over about the same distance from the a-c. source to the distributed d-c. load. The fundamental economy lies in the fact that, with distributed conversion equipment, the bulk distribution of this power is over a relatively high-voltage three-phase circuit, say 6.6-kv., instead of over a 250-volt d-c. circuit.

There are other advantages to be derived from the use of automatic equipment which, although more or less intangible and difficult of exact evaluation, are important and valuable. Automatic switching equipment provides a nicety of sequence and a fundamental correctness of all switching and control operations which cannot be expected under manual control. Experience in a wide variety of applications has demonstrated that this results in a higher standard of service reliability, freedom from long and expensive outage, and greater flexibility of system operation.

The Edgar Thomson works of the Carnegie Steel Company provides a typical example of a completely automatized system of d-c. power supply which has evolved gradually from the early days of centralized engine-driven equipment. The original installation comprised three engine-driven d-c. generators totaling 1,600 kw. and feeding out radially over a comparatively restricted area. As the d-c. load increased with plant growth more units and more distribution copper were added until the total engine-driven d-c. capacity at the power house was increased to 6,900 kw. including a 1,500-kw. gas-engine unit. With further expansion the load demand became so heavy that some decentralization of d-c. power supply was almost a necessity. Subsequent additions have been in the form of conversion units located at various points throughout the plant as shown in Fig. 1. The first three substations at first were manually operated because automatic switching equipment was not available at that time. They were automatized subsequently to secure improved operation and still better economy.

Fig. 2. A new 1,500-kw. automatic motor-generator set in the Edgar Thomson works

Fig. 3. D-C control panel for motor-generator set of Fig. 2

The present arrangement was completed with the installation of three new 1,500-kw. automatic motor-generator units similar to that shown in Fig. 2. One each of these units was placed at substations Nos. 4 and 5 and the power house. At the same time a similar manually-operated conversion unit in the power house was automatized. This permitted the retirement of all engine-driven d-c. equipment from active service, although the gas-engine unit and three steam-driven units were retained in place as standby capacity. The result is a complete automatic system of d-c. power supply consisting of 11,000 kw. of distributed automatic conversion equipment, all interconnected through the main distribution system.

The transfer of load from the centralized engine-driven units at the power house to conversion units near the load centers has greatly reduced the average d-c. feeding distance. The predicted saving in distribution losses has been realized in service. Furthermore, primary power now is generated in a relatively large and efficient turbine unit instead of in the small-capacity low-speed reciprocating units. Fig. 4 presents a contrast which illustrates the progress which has been made in the utilization of space and materials. One of the two 1,500-kw. motor-generator sets may be seen between the gas engine unit of the same rating and the

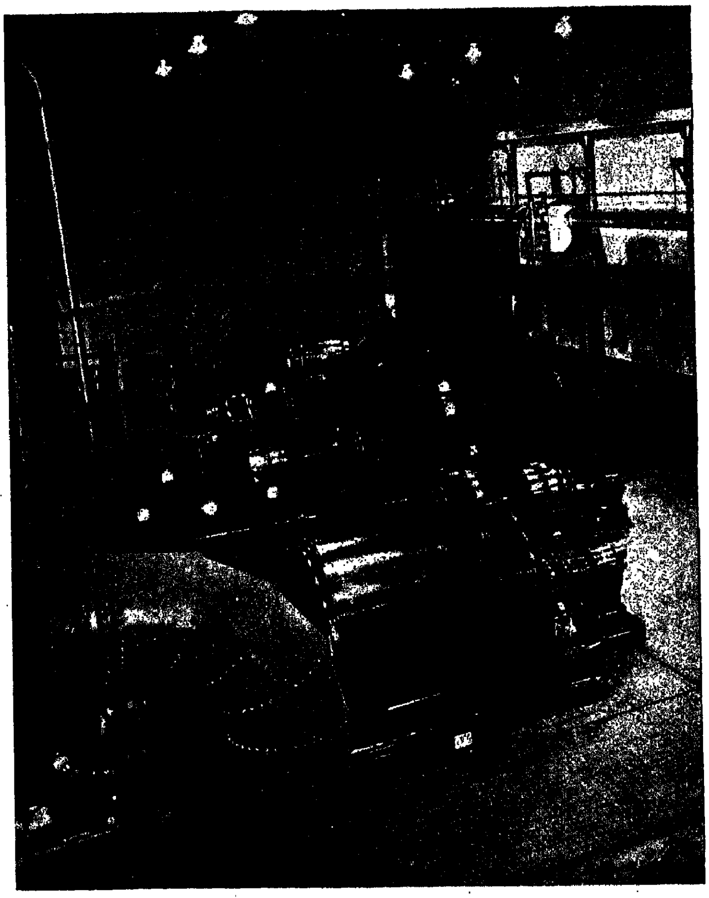

Fig. 4. A contrast in efficiency of space utilization between the old and the new

new 15,000-kva. turbine-generator. The picture was taken from the upper deck of the 1,500-kw. vertical cross-compound steam engine, giving some conception of its physical size.

It should be pointed out that the arrangement of this system necessarily differs to a certain extent from that which might be proposed for a similar, but entirely new installation. For that reason it probably is of greater value as a practical example because the problem ordinarily will arise in connection with the extension or rehabilitation of an existing plant. In any case it is important to realize that joint consideration of load and production requirements, d-c. distribution, substations, and a-c. power supply, is essential to a proper analysis and economical solution. It is only by such a study of the whole system of an industrial establishment that the major component parts can correctly be coordinated and proportioned.

Some Factors Affecting Stability

With the tremendous growth of power-transmission systems has come a corresponding increase in the seriousness of the stability problem. Regulation of generator excitation so that it will follow rapid changes in load constitutes a major part in the solution of this involved problem. Data show that the characteristics of all synchronous apparatus connected to a system must be considered.

By W. A. Merriam and H. R. Arnold**

Senior Students in Electrical Engineering (1929)
University of Colorado, Boulder

POWER limits of transmission systems present a problem which during the last few years has assumed a most important place in the electrical engineering field. When generators became larger, lines longer, and synchronous motors came into general use, it became apparent that some factor other than the temperature rise was beginning to limit the amount of power which could be handled. This factor has become known as the stability limit, and depends not only upon the design of the transmission line itself but also upon the characteristics of its associated synchronous generators and motors.

In the generation, transmission, and utilization of large blocks of power, the stability limit of a system is usually reached before the temperature of the apparatus has reached its maximum safe operating value.

As an example, reference is made to a report on the stability limits of the 220-kv., long distance transmission system of the Southern California Edison Company. This report disclosed that:

1. Adding a new plant and a second unit to the generating capacity at Big Creek would result in a hazard to the continuity of service because the stability limit of the system would then fall below the rated capacity of the combined power plants.
2. When the total system load became approximately 400,000 kw. or more, the condenser capacity then installed would not be sufficient to permit the 375,000 kw. rated output of Big Creek to be transmitted, without calling on the steam plants for wattless energy.
3. While the rated capacity of the Big Creek plant was 375,000 kw., its maximum stability limit with one line in operation was only 294,000 kw. and with two lines in operation, 370,000 kw.
4. The stability limit of that system could be improved by increasing the transmission lines up to a certain number. Should that number of lines be exceeded, however, the system stability would again be lowered.

CHARACTERISTICS OF SYNCHRONOUS MACHINES

In general the characteristics of synchronous machines are fairly well understood and do not need to be treated here in any great detail. However, for the purpose of bringing out those characteristics which bear directly upon the question of stability, a few of the important features will be outlined.

For a synchronous generator it may be said that:

1. The phase angle by which the terminal voltage lags the generated voltage varies with the magnitude and power factor of the load and also with the synchronous reactance of the machine.
2. That part of synchronous reactance which is due to armature reaction varies also with the magnitude and power factor of the load current; and with respect to the main field, may be either cross-magnetizing, bucking, or boosting, depending upon whether the load current is in phase, lagging, or leading with respect to the generated voltage.
3. In order to maintain a constant terminal voltage, the field current must be increased with lagging power-factor loads, and decreased with leading power-factor loads.
4. Decreasing the field current causes the generator to operate on the lower, unstable part of its magnetization curve, thereby decreasing the power limit above which it will drop out of synchronism.

From the foregoing statements it is obvious that any load on a generator which tends to raise the power factor or cause a leading current to be drawn decreases the stability limit of the machine since it reduces the load at which a synchronous motor connected to the generator in question will fall out of step with it. It also very materially decreases the synchronizing power and

*Now Assoc. A. I. E. E.

tends to cause the generator to fall out of step with other generators during line disturbances. If the field excitation of the generator could be quickly raised above normal during the time of a disturbance, the machine would be more stable and the liability of its losing synchronism would be greatly reduced.

A similar tabulation outlining those features of synchronous motors which bear directly upon stability limits is as follows:

1. Power factor depends upon both the field excitation and the load on the motor.
2. If the excitation is decreased below normal, the induced voltage or counter e. m. f. is less than the applied voltage, and the motor will draw a lagging current.
3. If the excitation is increased above normal, the induced voltage is greater than the applied voltage and the motor will draw a leading current.
4. Increase in load increases the angle between the applied voltage and the induced voltage. When these two are equal, the phase displacement at which breakdown occurs is 60 deg.
5. The breakdown or pull-out-angle, however, can be increased above 60 deg. by increasing the motor field current. Therefore, an overexcited synchronous motor is more stable than an underexcited one.
6. If the field current is kept constant, the maximum torque that the motor can exert will vary directly with the applied voltage.
7. If the field current is varied with the applied voltage, then the maximum torque that the motor can exert will vary as the square of the applied voltage.
8. Increasing the field current for any given load decreases the angular displacement between the induced and applied voltages. Also, with small field currents, this displacement increases the load rapidly; with large field currents more slowly.

THE TRANSMISSION LINE

Since an ordinary transmission line possesses both resistance and inductance, it would appear to have characteristics similar to those of a synchronous machine. The synchronous machine, however, has armature reaction which the transmission line does not possess; and the transmission line has distributed capacity which the synchronous machine does not have.

So far the discussion has shown that a load on the synchronous motor causes the rotor to lag behind the rotating magnetic field. This is the same as the load causing an angular displacement between the applied and induced voltages of the motor. We have seen also that a load on a synchronous generator causes an angular displacement between its total induced electromotive force and its terminal voltage.

In the same manner, the load on a transmission line will produce an angular displacement between the generated and receiving voltages. Should the load be increased to the limiting value of this angle, instability will result just as in the synchronous motor, and the apparatus at the load end of the line will pull out of step with the synchronous machinery at the sending end.

The vector diagram for a short transmission line carrying a lagging power factor load is shown in Fig. 1. The capacity of the line has been neglected. In this diagran, I is the load current per phase, R is the line resistance per phase, and X, the inductive reactance per phase; V_r and V_g are the voltages at the receiving and generating ends of the line, respectively. It may be seen that the generator voltage V_g is equal to the voltage at the receiver, V_r, plus the impedance drop through the line. The power-factor angle at the load is θ_r and the power-factor angle at the generator is θ_g.

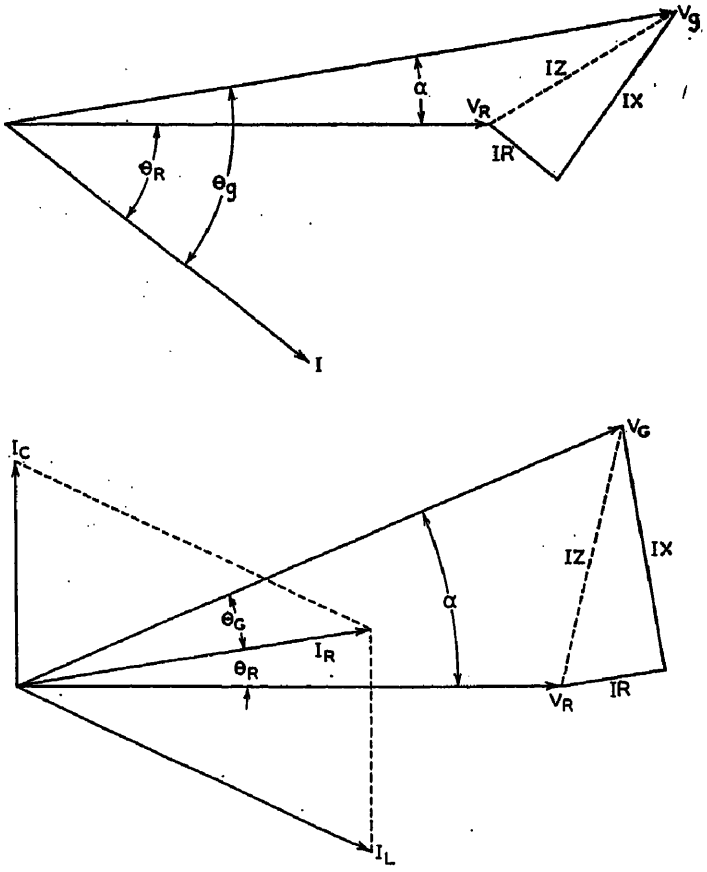

Fig. 1. Vector diagrams for a short transmission line (above) carrying a lagging power factor load; (below) a condenser load is added

Another important thing to note in this diagram is the angle α between the generator voltage V_g and the voltage at the load V_r. It can be shown that when the tangent of α is equal to X/R, α is nearly equal to 90 deg., and the line is then delivering its maximum power. In other words, when α approaches 90 deg., the line becomes unstable. (In actual practise, the limiting angle is somewhat less than 90 deg.)

Now suppose that a condenser is placed at the end of the line so as to raise the power factor; the vector diagram for this condition is shown also in Fig. 1:

The resultant current is now leading the receiver voltage but lagging the generated voltage V_g. The power factor at the generator has been raised, but at the same time the angle α has become larger than before, with the result that the limit of stability will be

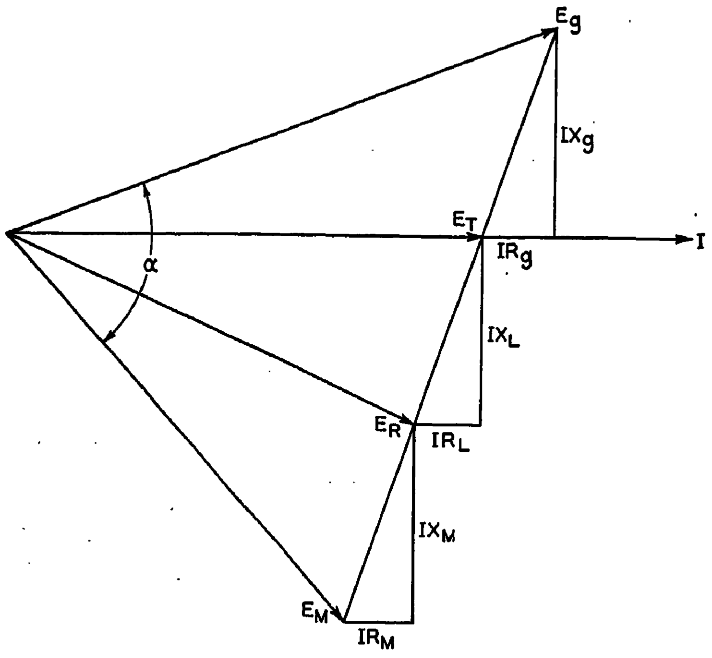

Fig. 2. Vector diagram for a synchronous motor connected through a reactive line to a synchronous generator

reached with a smaller value of current. In other words, the maximum power which the line can transmit has been reduced by adding the condenser load. Notice also that as the leading current in the line is increased, the receiver voltage may become larger than the generator voltage.

From the foregoing discussion and the diagrams in Fig. 1, it is obvious that the power limit of a transmission line can be increased by (1) decreasing the line impedance, (2) using generators and transformers of low impedance, or (3) using generators equipped with quick-acting relays which will cause the generator excitation to vary with the load.

Assume now that a synchronous generator and a synchronous motor are connected together through a transmission line having a certain amount of reactance; the vector diagram for these conditions will appear as shown in Fig. 2. Where, E_g is the total induced electromotive force of the generator, E_t is the terminal voltage of the alternator which is also the sending voltage of the transmission line, E_r is the receiver voltage of the transmission line which is also the terminal voltage of the motor, and E_m is the counter electromotive force of the motor.

When the angle α approaches 90 deg., breakdown occurs; but this breakdown takes place at a lower value of load and current than was the case with the motor connected directly to the generator terminals. With transformers added to the line, still greater reactance would be introduced into the circuit, and under these conditions the angle α approaches the stability limit more quickly with less load.

An oscillogram showing the voltage and current relations in a synchronous motor as instability occurred is shown in Fig. 3. The armature current of the motor may be seen to rise with load and then become unstable as breakdown takes place and the rotor drops out of step. The motor terminal voltage also may be seen to drop abruptly as the pull-out occurs. The field current is interesting because as the rotor slows down it has superimposed upon it an alternating voltage of increasing frequency.

It is now quite clear that an understanding of the problem of system power limits includes a detailed study of the characteristics of every piece of electrical apparatus involved, as well as the transmission line itself.

Another very important point to mention is the fact that raising the power factor may decrease the stability of the system, and that the power limit of a system may actually be greater for low power factor than for a higher power factor. Distributed capacity in the line may also lower the power limit, since it raises the power factor at the generator, thus reducing the field current necessary to produce rated voltage, at the same time decreasing the stability of the machine. This serves to emphasize again the important part which generator excitation plays in stability limits.

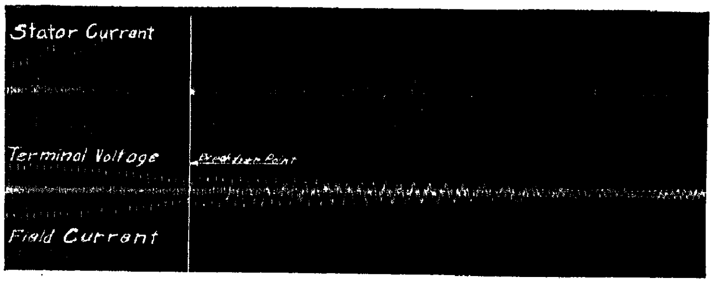

Fig. 3. Voltage and current relations in a synchronous motor at time of breakdown

STABILITY TESTS MADE

The effect of the generator and an inductive line upon the pull-out load of a synchronous motor is shown in Fig. 4. Data for these curves were the results of a test conducted as follows:

First a 25-hp. synchronous motor was connected to a bus of high capacity; the pull-out load and angular displacement was then noted. This pull-out load was 64 kw., and the angular displacement at the motor was 66 deg.

Then the motor was connected to the terminals of a

15 kva. generator and again the pull-out load was noted. This second pull-out load was found to be 32 kw., or one-half the first value, the displacement angle being only 39 deg.

In the third test the motor was connected to the generator through a reactive line. This time the pull-out load was only 18 kw. and the displacement angle 30 deg.

It may be seen at once that the introduction of the generator into the circuit had a much greater effect in reducing the pull-out load of the motor than did the transmission line. It is for this reason that most of the efforts to stabilize power systems are concentrated upon the generator.

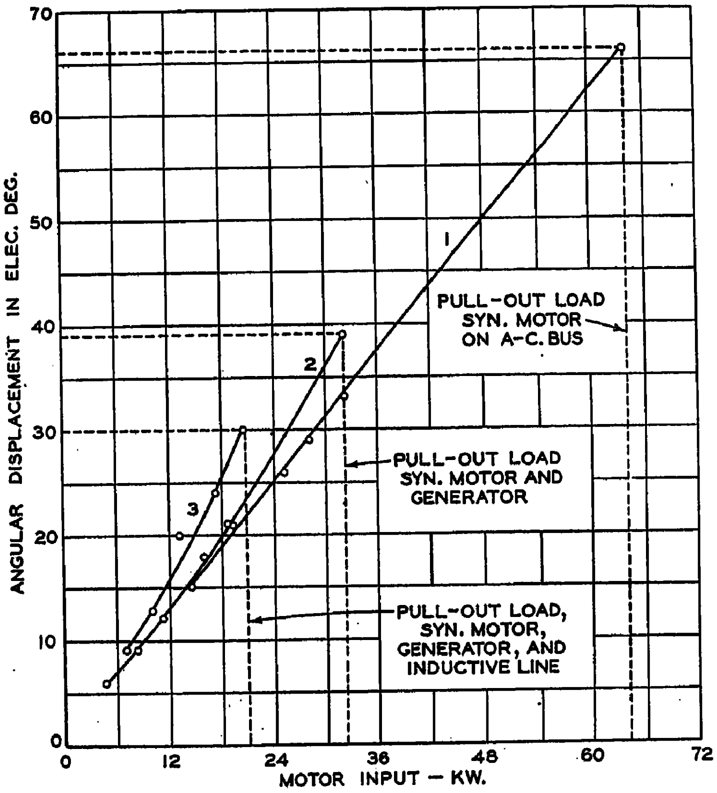

Fig. 4. Pull-out loads for a synchronous motor connected in various ways

Means for Improving Stability

Several means for improving the stability of power systems in order to raise the power limits have been proposed or investigated. Some of these are enumerated as follows:

1. Vary the excitation of generators with the load.
2. Load the bus at the generating station with reactors to lower the power factor on the generators without lowering the power factor of the transmission lines. This would also allow for increased generator excitation, resulting in an increased system power limit.
3. Partially replace synchronous apparatus with induction generators and motors.
4. Lengthen air-gap of generators to increase degree of magnetic saturation.
5. Intermediate condenser stations may be placed at points along the line.

There is no doubt that the most important factor lies in providing generator excitation to follow rapidly any change in load. A new method of increasing the field current as the load increases has been investigated at the electrical laboratories of the University of Colorado with marked success. When the apparatus was devised it was first thought that the idea was entirely new; it was soon learned however, that a similar idea was being developed by the General Electric Company.

The new device acts to greatly increase the generator excitation as the load increases, regardless of what the voltage or power factor might be. A diagram of the apparatus is shown in Fig. 5. Here a generator is connected to a synchronous motor through a reactive line. In the line near the generator terminals are placed three current transformers with their secondary windings, Y-connected to the terminals of a small three-phase induction motor. When a load is thrown on the synchronous motor, the currents in the windings of the current transformers increase, thereby causing the rotor of the induction motor to produce torque in a counterclockwise direction. This lowers a contact into a water rheostat, decreasing its resistance and thereby increasing the field of the generator which enables the system to remain in synchronism. The device is extremely simple, and its efficiency has been demonstrated many times under all kinds of circumstances. A similar device to regulate the slip of large induction motors already is in use.

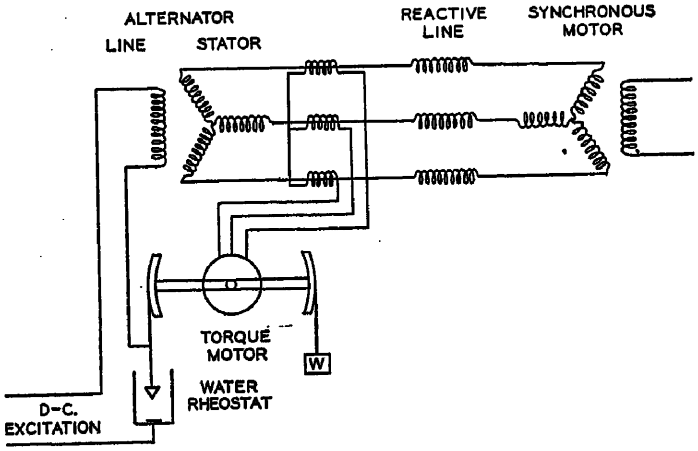

Fig. 5. Arrangement for enabling generator field current to follow rapid changes in load

Several tests have been made by over-exciting a synchronous motor; then loading it to the breakdown point. As already pointed out, the breakdown point under this condition is low, with no regulator of this kind in the circuit. With a leading power factor of 95 per cent, the breakdown point was found to be 22 kw., and the angular displacement 21 deg. Then the same test was repeated with the new excitation regulator. This caused the generator field current to be raised from 2.5 to 8.5 amperes as the load increased, and the breakdown point was raised to 25.5 kw. at an angle of 24 deg.

Another example might be interesting. By means of the over-excited synchronous motor the alternator was was loaded to capacity, whereupon an induction motor of the same rating as the alternator was thrown directly on the line; of course the system pulled out of step. This was repeated with the excitation regulator in the circuit, with the result that the system remained in step and the synchronous motor continued to carry its load as though nothing had happened.

Any scheme of generator field regulation which will, allow the excitation to follow rapidly any changes in the load as this system does should go a long way toward solving the stability problem.

The system just described has the added advantage of remaining operative even under badly unbalanced load conditions.

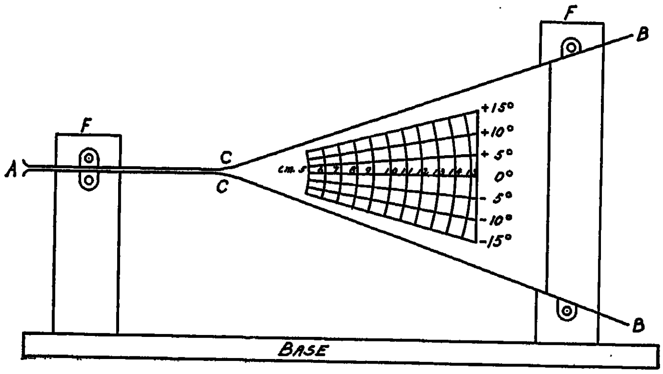
Determining the Flexibility of Mica Sheets

WITH the desire to make possible closer grading and duplication of flexible mica sheets, an apparatus called the "fleximeter" has been developed for the New England Mica Company by W. R. Mansfield of that company, and Willis A. Boughton of the Harvard College chemical laboratory

This apparatus (see illustration) is a simple device for measuring empirically the free bending length of a sample strip of the flexible sheet that while in continuous motion downward under pull of gravity, covers a selected arc in a definite time. The following empirical specifications have been selected as giving convenient and rational values:

1. Test strip, 5 cm. wide, 20 to 25 cm. long, and 0.015 in. thick.
2. Horizontal position taken as 0 deg.
3. Arc over which fall is free, + 15 deg. to − 15 deg.
4. Arc over which time of fall is read, 0 deg. to − 10 deg.
5. Time of fall for free end, 10 sec.



Front view of "fleximeter" for mica testing

A test strip is inserted between the pieces *A C* (which are about 6 cm. wide, front to back) is held at the *A* end with the left hand, and stretched against the upper strip *C B* with the right; it is then released at the *B* end and allowed to fall free. The length which will thus fall from zero to the − 10 deg. line in exactly 10 sec., is determined by trial.

This free length of the test strip which requires exactly 10 sec. to fall from zero to − 10 deg., expressed in *millimeters*, is called the fleximeter number and represents the non-resilient flexibility of the sheet.

After the first test on any particular specimen, the strip is turned over and the test repeated. The piece is then turned end for end and another pair of readings taken. Thus four lengths are obtained, the average of which is taken as the fleximeter number. Data illustrating the method and its application to several variety of plates are shown in the accompanying tabulation.

FLEXIMETER NUMBERS OF FOUR FLEXIBLE MICA SHEETS

Sheet No.	Mm. lengths giving 10-sec. fall 1	2	3	4	Avg. length or fleximeter No.
9	58	56	59	54	57
11	67	62	66	65	65
12	77	81	95	86	85
16	114	126	118	120	120

Differences in flexibility such as are indicated between sheets Nos. 9 and 11 could not be distinguished by ordinary inspection and handling; sheet No. 12 was apparently only slightly stiffer than these two, while sheet No. 16 would ordinarily be considered only a grade or two less flexible than the others.

A High-Speed Submarine Cable

Higher transmitting speeds than had been attained previously were made possible in 1928 by the installation of the high-speed loaded cable between Newfoundland and the Azores. Some of the design features and problems involved in duplex operation are described.

By J. W. Milnor and G. A. Randall

Fellow A. I. E. E. Non-Member

Western Union Telegraph Co.
New York

A SUBMARINE telegraph cable of a new type was laid in September 1928, connecting the Western Union Telegraph Company's cable station at Bay Roberts, Newfoundland, and Horta, Azores (See illustrations). This cable combines the facilities for duplex, or two-way operation inherent in non-loaded cable, with the high-speed characteristics of the new, loaded type. Tests on this cable have shown that a duplex speed of at least 1,400 letters per min. (42 cycles per sec.) simultaneously in each direction is now practicable. If operated simplex,—*i. e.*, in one direction only,—the speed is over 2,500 letters per min. It therefore provides the greatest message-carrying capacity of any existing transocean cable.

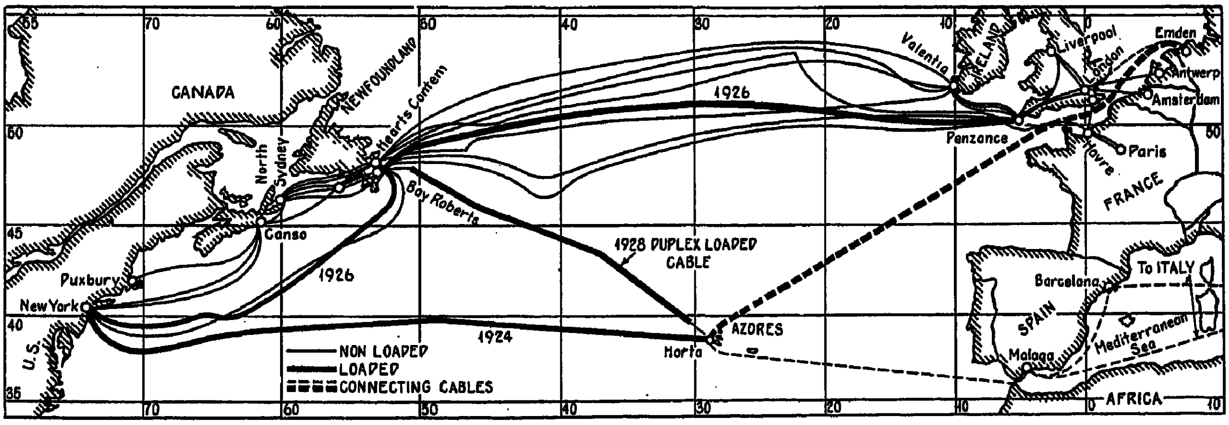


Fig. 1. Western Union cable system in the North Atlantic

The first long continuously-loaded submarine telegraph cable was laid in 1924; since then, eight other loaded cables of similar construction have been laid by various companies. These cables have several times the operating speed of non-loaded cables, but their electrical characteristics are such that they are much more difficult to duplex, and, therefore, have been operated simplex only. There are many situations, however, where duplex operation is decidedly advantageous, consequently it was inevitable that attempts should be made to develop a type of cable capable of high-speed duplex operation.

General Theory of Duplex Cables

In order to duplex a cable, it is necessary to provide at each terminal station a so-called "artificial line," the impedance of which must closely match or "balance" that of the cable throughout a range of frequencies from about half the fundamental signaling frequency up to about 1.6 times that frequency.

A loaded cable is more difficult to balance for three reasons: (1) There are larger irregularities in the impedance measured at different points; (2) the effect of such irregularities upon balance is more pronounced in a loaded cable; and (3) the inductance and effective resistance of loaded cable undergoes continuous, small variations in accordance with the changing magnitude of the signaling current.

Each of these difficulties may be reduced in importance by loading only the central portion, and suitably designing each section. For the non-loaded portion the duplex balance may have about the same high accuracy as has been customary in the past in non-loaded cables. In the part of the artificial line corresponding to the loaded portion, a duplex balance of a much lower degree of accuracy is sufficient.

Some of the various factors affecting accuracy and stability of balance, are: (1) The attenuation from end to end of the cable as measured at working frequencies; (2) the attenuation from end to end of the loaded portion of the cable; (3) the "current coefficient of inductance," *i. e.*, the fractional rate at which the induc-

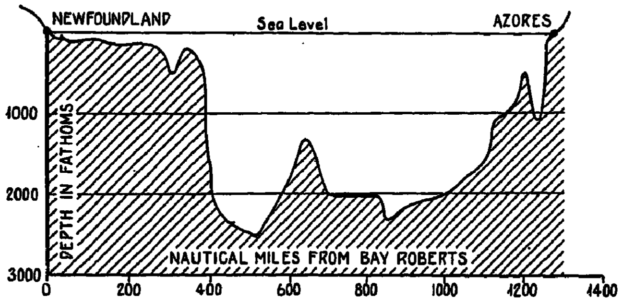

Fig. 2. Profile of ocean bottom route of the 1928 cable

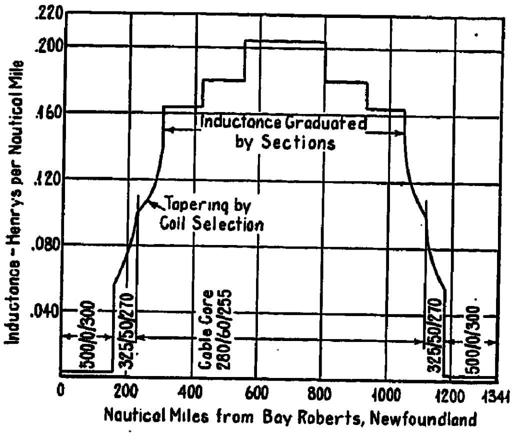

Fig. 3. Inductance of different sections of cable

tance of loaded cable varies with current; and (4) tapered loading.

DESCRIPTION OF 1928 CABLE

The total length of the cable is 1,341.2 nautical miles. Each non-loaded end portion is 160 miles in length; the heavily-loaded central section is 881 miles in length, while intermediate between these two types there are sections of lightly-loaded cable, each 70 miles in length. Further details of the design and electrical characteristics of each section are given in Table I.

TABLE I—CHARACTERISTICS OF CABLE CORE FOR DIFFERENT SECTIONS

Factory values per nautical mile, at 75 deg. fahr.

	Sections		
	Ends	Intermediate	Center
Weight of copper—lb.	508	329	284
Weight of loading—lb.	non-loaded	51	60
Weight of gutta percha—lb.	303	275	258
D-c. resistance—ohms	2.34	3.60	4.18
Capacitance—μf	0.357	0.344	0.342

The loading throughout the central and intermediate portions is Mumetal wire supplied by the Telegraph Construction and Maintenance Company, Ltd., of London. This material is similar to permalloy. A permeability range from 2,000 to 6,800 was obtained in different sections of the cable by controlled variations in the annealing process. The average values of inductance are given in Fig. 3.

In order to reduce extraneous voltages picked up in shallow water it is customary to carry a second and sometimes a third core in the sections near the ends. At Bay Roberts the receiving sea earth is 50.1 nautical miles long and is grounded to the cable sheath through a resistance of 160 ohms. At Horta, Azores, the corresponding length is 2.39 miles and is grounded directly to the sheath.

CABLE TESTS

Various tests were made on the cable both during manufacture and also after it was laid. The total d-c. resistance is 4,521 ohms; the total capacity 463 μf.

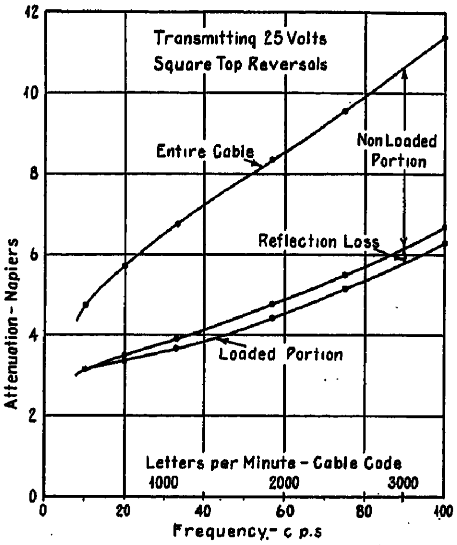

Fig. 4. Attenuation of laid cable

The results of some of the attenuation tests with square-topped transmitting waves are shown in Fig. 4.

The time of propagation of signals over the cable is 0.235 sec. at 60 cycles. It has been estimated that during the process of laying, the mechanical strains placed upon the cable caused an average of about 13 per cent loss in the inductance.

ARTIFICIAL-LINE EQUIPMENT

An essential part of this cable project has been the provision at each cable station of an adequate artificial line for completing the Wheatstone bridge arrangement which is necessary for duplex operation. The present equipment is somewhat more complicated than in the case of the usual artificial line for low-speed cables. In addition to resistance and capacity elements, the present equipment includes means for simulating the inductance of both loaded and non-loaded portions, the eddy-current losses in the loading, sea-return losses, and dielectric losses. A compensating arrangement is introduced to prevent "filter oscillations" between the condenser and inductance units.

As in the case of the cable itself, the change of inductance with current in the coils of the artificial line was given consideration and was held to a relatively small amount. It was also necessary to exercise unusual precautions to guard against the effects of temperature changes and of pick-up of extraneous disturbances by the coils.

It has been estimated that for transmission of telegraph characters, the impedance of the artificial line matches that of the cable to an accuracy of roughly one part in 4,000, and for sine waves in the range between 35 and 55 cycles, better than one part in 7,000.

Merits of Simplex and Duplex Cables

In determining the kind of cable facilities best suited for handling telegraph traffic between two given areas, there are many factors which must be considered; among these are the length of the circuit, the desired message capacity, the relative amounts of urgent and deferred traffic, the difference between the loads in each direction, the difference in time between the terminal areas, the nature of existing cable facilities, and the handling of traffic in case of failure of one or more cables.

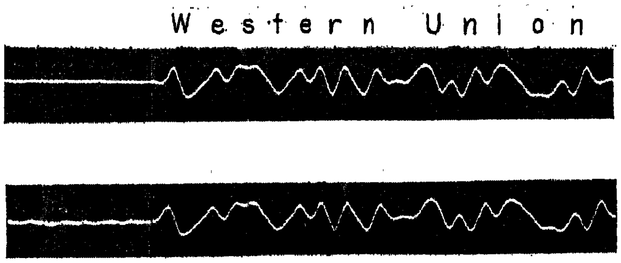

Fig. 5. Cable-code signals as received at Bay Roberts showing in the upper record simplex westward transmission, and in the lower record duplex eastward and westward transmission

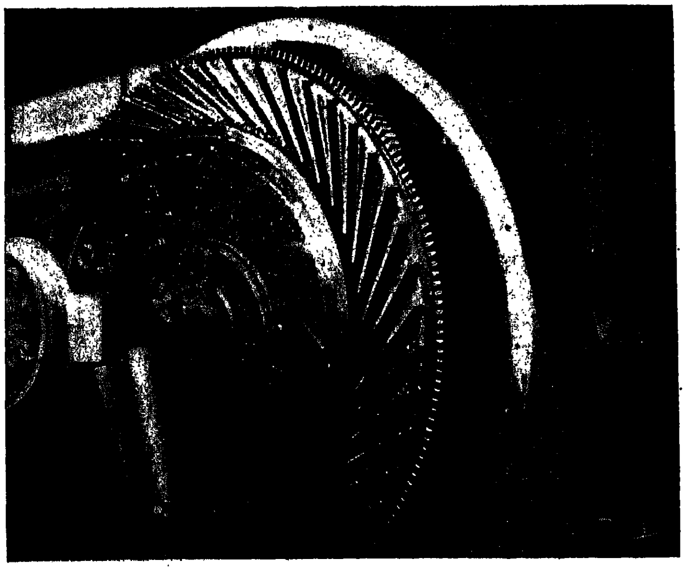
Where the load is sufficient to justify only a single cable, and the difference in time between the terminals is not excessive, the duplex type usually offers the most convenient solution. If the terminals are so located that there is a considerable time difference, the simplex cable has the advantage. Where the amount of traffic is enough to justify two or more cables, there are various possible solutions; in some cases it is probable that a combination of simplex and duplex cables is the best solution. It also appears probable that neither the simplex nor the duplex cable has as yet reached its limit of economical development; hence, it is hardly practicable at this time to give a final answer to these questions.

Metal-Clad Synchronous Motors Latest Thing for Nitrate Plants

Working in an atmosphere of fine nitrate dust, the 250-hp. Westinghouse synchronous motor shown under construction in the accompanying illustration, obviates the usual danger of nitric-acid damage to its windings. Built to fit their job, the vulnerable parts of these motors are metal-clad and in addition are supplied with a slight static pressure inside to prevent the harmful dust from leaking in. Inclined fins on the metal enclosure not only throw off heat, but guide along the most efficient route the cooling air supplied by the fan on the rotor. Without these odd-looking fins the operating temperature of the motor would be much higher. These motors are designed to operate on 550-volt, 60-cycle circuits and have a synchronous speed of 450 r. p. m.

Although built to meet many requirements which do not handicap the usual open synchronous motor, these motors are only about one-fifth larger than the ordinary type. Besides being protected from nitrate dust, they produce 120 per cent starting torque and 100 per cent pull-in torque—about twice the usual values. Rated at 90 per cent leading power factor these motors will carry full mechanical load while also furnishing power-factor correction. And although they work a mile above sea level in rarefied atmosphere, the temperature rise is but slightly more than usual, being rated at 55 deg. cent. for El. 5,000 ft.



One of the 250-hp. synchronous nitrate-crusher motors built for the Anglo Chilean Corporation. Note the metal enclosures protecting the windings; cooling fins serve also as guide vanes for circulating air

Noise—

With America becoming "noise conscious," electrical engineers are finding it necessary to devote increasing attention to the reduction of noises caused by electrical machinery. Progress in this direction, both in specially designed instruments and in mitigative measures adopted, is indicated in the accompanying articles.

NOISE is a comprehensive term which includes almost all sounds except music and speech, and covers the entire audible range both in loudness and frequency. Noises set up by electrical machinery are caused chiefly by vibration of the machines as a whole or in parts, and are usually recurrent and approximately steady as contrasted with the random character of ordinary street noises. The resultant noise perceived by the ear, however, is in the main a mixture of two components, one emanating directly from the machines and the other radiated from the floor and walls of surrounding enclosures.

In order to control noise a thorough understanding not only of the causes but also of the mode of transmission of noise is necessary. It is in this aspect of the problem that accurate measurements are especially helpful and with instruments now available information may be obtained which will serve as a basis for changes in machine design. There is a tendency, however, to reduce the size and weight of machines due to the improved electrical and magnetic materials now available. This complicates still further the already difficult problem of designing quiet machinery, since the lighter structures are more susceptible to vibration.

Difficulties in Measuring Machine Noise

By
B. F. Bailey
Fellow A. I. E. E.
University of Michigan
Ann Arbor, Mich.

WHEN a new and useful machine is first introduced, nobody thinks much about possible refinements. Thus when electric motors were first used, reliability was the essential quality. Soon afterward price became of importance; still later, efficiency was considered. At the present time attention is being turned to noise and the point has now been reached where the need of adequate means for noise measurement is felt. At present the intensity of a noise is stated about as accurately as the Irishman's reply that a certain object was "about as large as a lump of coal."

Two distinct types of measuring devices are needed: One, if possible, to give an indication of the intensity of a sound with a single reading in the same manner in which an ammeter gives at once the current in a circuit; the other, to make possible the analysis of a sound into its component parts in much the same manner that the components of a current can be analyzed by means of the oscillograph. The first type will be useful to the manufacturers and users of machinery in determining quickly and easily whether a machine comes within certain prescribed limits of quietness. The second type will be useful to the machine designer by enabling him to determine and eliminate the sources of noise.

DIFFICULTIES OF THE PROBLEM

When an attempt is made to develop an instrument which will give an objective indication of the degree of noise from a given source, serious difficulties are encountered. Unfortunately the effect upon the human ear is not directly proportional to the physical intensity of the sound. A sound of very high pitch, for example, cannot be heard at all; and the same is true of sounds of very low pitch. Moreover the range over which the ear can hear varies with different persons and at different times. The problem is further complicated by the fact that what is really desired is to find out how disagreeable a certain noise is regardless of its intensity.

Another difficulty arises from the fact that in an ordinary room not only is the sound itself heard but also many reflections of that sound. A sound indoors at a certain distance may easily produce ten times the effect of the same sound at the same distance in open air. Moreover in any ordinary room the sound will be focused at certain points and consequently will be much louder there than at other parts of the room, and sometimes even louder than at the object emitting the sound. One obvious remedy is to make all tests in sound-proof rooms. But while this is possible in the laboratory, serious difficulties would be encountered in applying the method to routine production. A method

used with some success is to provide a very large rotating vane to break up reflections and prevent them from concentrating at any one point.

As previously indicated there is need also for some means by which sound can be analyzed into its various components and the intensity of each of these determined. One method now in use consists in using a microphone to pick up the sounds which in turn are amplified by vacuum tubes and then passed through a variable filter. Since only one component passes through the filter at a time, it can thus be measured by a galvanometer or similar indicating device, a method, which while obviously slow, gives complete information in regard to the sound produced and is unquestionably of great value to the designer.

ORGANIZATIONS INTERESTED

Several manufacturers of various types of machinery have become greatly interested in methods for measuring accurately and quickly the noises produced by their products. In the past five years approximately $250,000 has been spent upon such projects at the University of Michigan alone; methods have been devised for measuring the noise produced in ball and roller bearings, gears, electric carpet sweepers, and other devices; instruments have been constructed and are now being used in routine production in several factories.

Certain national societies, among them the National Electrical Manufacturers Association and the American Society of Mechanical Engineers, have become interested in the problem and have appointed committees to consider the subject. The committee of the former organization was instructed first to find or devise a method of measuring the noise produced by electrical machinery; then, when such a device has been found, to formulate standards of allowable noise for this machinery. Some of the difficulties in the first part of this problem have already been indicated. Considering even the enormous variation in horsepower, speed, frequency, and number of phases, of electric motors alone, it will be apparent that the difficulties of the second part of the assignment are no less than those of the first part.

CONCLUSIONS

It is evident that the American people as well as the manufacturers of electrical machinery are becoming "noise conscious." Great progress has been made within the past few years in devising means for measuring noise as well as improving machinery so that it will be less noisy. Although the difficulties of the problem are great, there is reason to hope that in the near future some device will be perfected to give an immediate indication of the effect of any given noise upon the human ear. After all, what is desired is to eliminate noise. But with such an instrument available progress will be much more rapid for a definite measure of noise will then have been achieved in place of the present imperfect estimate based entirely upon personal judgment.

A New Meter for Noise Analysis

By
T. G. Castner Non-member — Bell Telephone Laboratories, Inc., New York
E. Dietze Non-member — American Telephone & Telegraph Company, New York
G. T. Stanton Associate A. I. E. E. — Electrical Research Products, Inc., New York
R. S. Tucker Associate A. I. E. E. — American Telephone & Telegraph Company, New York

A SOUND METER has recently been developed in the Bell System, which measures acoustic noises and sounds in general. The aim has been to have its indications accord with present information on the response of the ear as far as practicable in a simple portable device. The response of the meter to sound impulses, in general an important part of noise, has been carefully considered. There is also under development an attachment to analyze sound both on a single-frequency and band-frequency basis.

The meter consists of a sound-pick-up device to convert acoustic into electrical energy, a multi-stage vacuum-tube amplifier, a calibrated gain control to measure sound levels over a range of 90 db. (corresponding to a range of 1,000,000,000:1 in input powers), an electrical network to weight different frequencies in a manner similar to that in which they are weighted by the ear, a rectifier and visual indicating meter which responds in a manner similar to the ear, and means for over-all acoustic calibration.

Calibration is in terms of physical units rather than in some other terms which might depend upon the "personal equation." The sound meter is calibrated in terms of a 1,000-cycle pressure of 0.001 dyne per sq. cm. in a free progressive wave which pressure is called the "reference sound level." Sound levels measured are expressed in decibels above this reference point. For a 1,000-cycle tone, this reference level is somewhat above the minimum threshold of audibility of the average observer.

NOISE AND HEARING

In the design of a meter of this type, certain physical characteristics of noise and hearing must be considered in order that its indications will be correlatable with noise effects. These effects are known to vary with time in many different ways but the important part played by the sharply peaked wave forms of some noises generally is not fully realized.

Principal characteristics of hearing taken into account in the design of the meter are those relating the sensation of loudness to the physical properties of a sound, such as intensity (sound power passing through unit area), frequency, duration, and complexity of wave shape. This subject is not discussed here as a great deal has already been published regarding it.

DESCRIPTION OF SOUND METER

Usefulness of a device for general noise measurements depends largely upon portability, as in most cases the meter must be taken to the location of the noise. For this reason, therefore, the sound meter has been made small and light. Fig. 1 shows a schematic layout diagram while in Fig. 2 is shown an experimental model of the meter. Batteries are contained in a separate box but both units together can be carried easily by one man.

2 STAGE AMPLIFIER AND RECTIFIER
INDICATING METER
TO ANALYZER
CALIBRATING OSCILLATOR

Fig. 1. ***Layout of noise meter showing arrangement of component parts and calibrating apparatus***

The meter is capable of measuring noise magnitudes from about 10 to 100 db. above reference sound level, and covers a frequency range from about 50 to 10,000 cycles per sec. It is direct reading in db. above reference sound level, and weights noise components at different frequencies approximately according to the 40 db. curve of Fig. 3. An adjustable frequency-weighting is not thought necessary since it would not appreciably change the results of more than a small proportion of the measurements.

A full indication on the meter is obtained in about 0.2 second. The fact that a 0.2-sec. response approximately simulates that of the ear can be demonstrated by watching the movements of the needle of a meter having this response and at the same time listening to the variation of the noise. In such a test the visual and aural impressions are approximately synchronized. Measurements of certain noise impulses taken with this meter and with a meter requiring about 5 sec. to reach full indication gave differences in the readings on the same impulses amounting to about 15 to 30 db.

The output circuit of the sound meter follows approximately a "square law;" that is, the meter reading is about the same for a sinusoidal voltage as for a steady

---

From "Indicating Meter for Measurement and Analysis of Noise," (No. 31-80) presented at the North Eastern District meeting of the A. I. E. E., Rochester, N. Y., April 29-May 2, 1931.

complex voltage of the same r. m. s. value. Thus the reading is a function merely of the average impressed power and not of wave shape. The reading should preferably not depend upon phase relations, which are affected by phase shift in the meter.

The meter has been designed so that its readings with negligible error for common noises are proportional to the input level over the whole 90 db. range provided. It is practically completely shielded against electrostatic fields. The shielding provided against stray electromagnetic fields is believed to be sufficient for practical purposes.

Calibration

Primary absolute calibration of the sound meter was made by placing the sound pick-up in a 1,000-cycle free progressive wave at a point at which the pressure was determined from Rayleigh disk measurements.

Great care has been taken to make the meter electrically stable. In addition, in order to verify in the field that the meter is reading correctly, a means for making an over-all acoustic calibration has been provided. The apparatus for this secondary calibration consists of a stable telephone receiver, a 2,000-cycle oscillator, and a means for coupling the receiver to the sound pick-up. This calibration may be made in a few seconds.

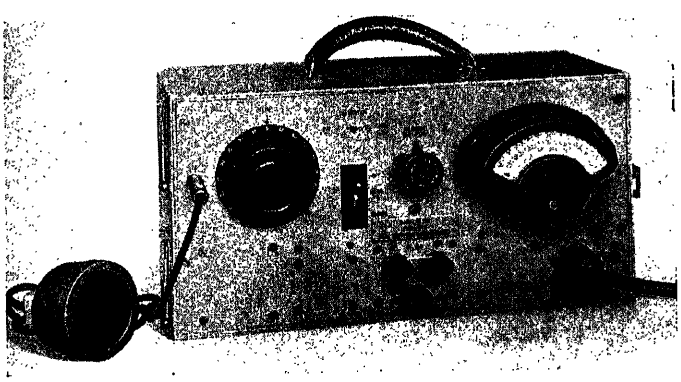

Fig. 2. An experimental model of sound meter with pick-up device at the left

An attachment to the sound meter is now under development, by means of which either a quantitative frequency analysis of a sound or a measurement of the amount of sound energy in various frequency bands can be made easily and quickly.

Uses of Sound Meter

The sound meter is applicable to a great many acoustic problems. It is necessary, however, to take care that sounds other than those under investigation do not affect the measurements, and to take account of the test conditions in the interpretation of the results, *i. e.*, the acoustic properties of the surroundings, the location of the pick-up with respect to the noise sources, and other influencing factors.

This meter can be used to make noise surveys; to aid in ascertaining desired levels of noise in various cases, and determine when these levels have been met; to measure machine noises; to measure noise in residential neighborhoods where power substations may be installed; and to measure sounds other than noise (in recording and broadcasting work, for example, to determine optimum levels and sound distributions).

With the analyzer more detailed information will be obtainable than is furnished by over-all sound measurements alone. This device will aid in determining whether an undesired sound will be covered up by the general noise, or whether a signal will be audible through this noise. Determination of the frequencies of noise components permits selection of the sound-absorbing material most effective in reducing noise. Determination of the noise components of a machine may yield data as to the contribution of each individual noise source in the machine; such data can then be applied in the redesign of machines to reduce noise. The control of uniformity of manufactured products by means of acoustic measurement also offers a potential field of application for the sound meter.

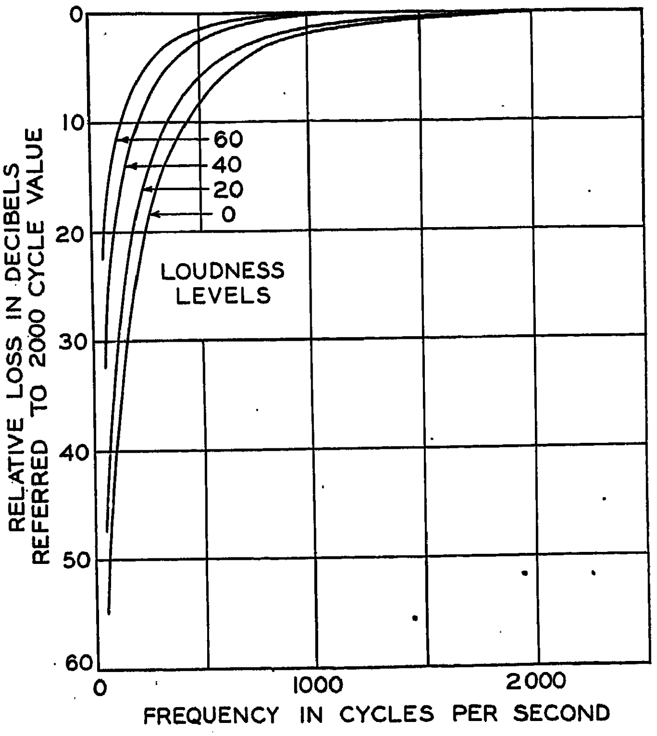

Fig. 3. Frequency weighting curves for equal loudness

By means of a suitable electrical input the sound meter may even be used in certain cases to measure electrical levels or to analyze electrical quantities; but it is believed that this new meter will prove of greatest value in the study of noise and sound problems which are almost daily increasing in variety and complexity.

Magnetic Noise in Synchronous Machines

MAGNETIC NOISE in synchronous machines, particularly those of the low-speed class, has been a source of annoyance to both designers and operators, but literature on the general subject of noise is notably free from any discussion of the specific causes of noise in this type of machine. In this article an attempt is made to point out some of the causes of this noise and to show the extent to which they may be controlled by the designer.

When the noise problem in synchronous machines was first investigated several years ago there was a great deal of speculation concerning the particular part of the machine that produced the principal vibration. Suspicion pointed to the stator teeth, the overhanging tips of the poles, and the poles as a whole. It finally became evident, however, that one of the principal sources of noise was the vibration of the stator as a unit.

The most frequent cases of stator vibration arise from flux distributions which, because of unequal magnetic pull on all axes, make the stator to assume an elliptical shape. This condition requires, in effect, a two-pole flux distribution superposed on the normal distribution. It will be shown later that there are several ways in which such a flux distribution may be set up. It is also possible to have a four-pole (or more) distribution which will tend to distort the stator at four (or more) points. Since the stator structure is much more rigid with respect to these forces than to the two-pole force, they are not such frequent sources of trouble.

Rotor vibration takes more forms than stator vibration. One possibility is for the rotor rim between arms of the spider to move in and out, either in phase or 180 deg. out of phase, with the segment between the succeeding spider arms. Another possibility is for the poles to vibrate circumferentially. A third mode of vibration occurs when parts of the spider rim vibrate axially. This last type of motion resembles that occurring in gears.

Under certain conditions it is possible to have magnetic forces tending to pull the rotor out of center. This requires a distribution of force having only one wavelength in the circumference of the machine. It might be called by analogy a one-pole distribution and is similar to what occurs when the air-gap is unequal. Such forces are found in induction motors[1] (for numbered references see bibliography) but would occur in synchronous machines only if odd numbers of slots were used. Since the number of slots in synchronous machines is almost invariably an even number, especially in large machines, this type of vibration rarely occurs and will not be discussed here in detail.

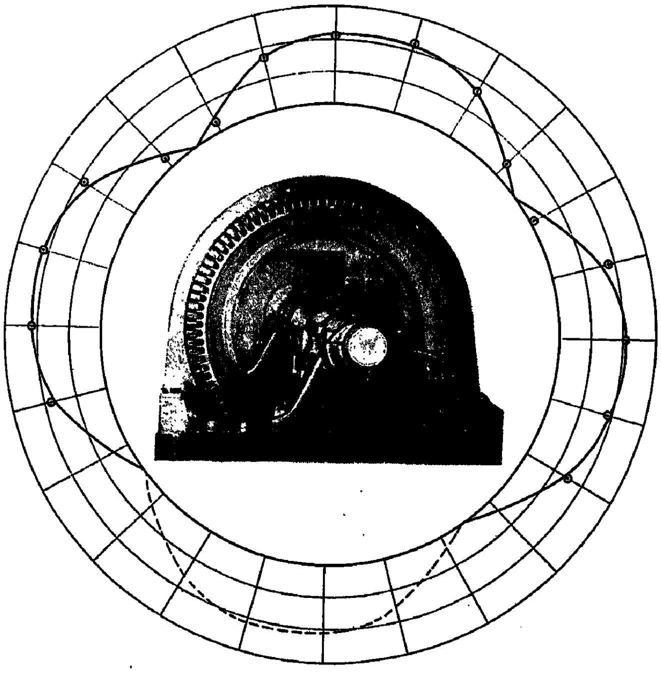

Fig. 1. Pole-frequency vibration around the circumference of the stator. The motor in the center is correctly oriented with respect to the measurements

Two important classes of noise or vibration with reference to frequency have been noted; namely, (1) tooth frequency noise, usually occurring at no-load and independent of armature current, but sometimes proportional to or increasing with it; (2) pole-frequency noise or noise of twice the line frequency which depends upon the armature current and is thus much lower in tone than the other type of noise.

It is realized that noises of other frequencies may exist but as they are relatively unimportant they will not be considered here.

TOOTH-FREQUENCY FORCES

In order to explain the cause of tooth-frequency noise, it is convenient to consider the change in flux of a single pole as it moves over one stator tooth pitch. Clearly there is some point where the flux is at maximum and some point where it is at minimum; thus the flux in each pole rises and falls slightly each time a tooth pitch is traversed, and the magnetic pull between that pole and the stator goes through a corresponding cycle. Assume for example that a machine has 14 poles and $5^{1}/_{7}$ stator slots per pole; it is evident that if Pole No. 1

From "Magnetic Noise in Synchronous Machines," (No. 31-78) presented at the North Eastern District meeting of the A.I.E.E., Rochester, N.Y., April 29-May 2, 1931.

has maximum flux at a given instant, Pole No. 2, 1/7 tooth pitch from the same relative slot position will have slightly less flux. Each succeeding pole will have a little less flux until the minimum is reached, after which there will be a gradual increase. Thus there will be two areas diametrically opposite having high flux density and two areas on an axis at 90 deg. to these, having low density. The result is a higher magnetic pull along one axis and a tendency to give the stator an elliptical shape.

It now remains to see what happens to the magnetic pull or stator distortion as the field member rotates; using the given example, it may be seen readily that when the rotor has moved 1/7 tooth pitch, the point of maximum density has shifted from Pole No. 1 to Pole No. 2. When a tooth pitch has been traversed, the point of high density has moved seven pole pitches as measured on the rotor. With reference to the stator, the distorting force has moved seven pole pitches plus one tooth pitch. Thus it may be seen that a given point on the stator goes through a complete cycle from maximum pull, through minimum pull, and back to maximum, while the rotor moves slightly less than one tooth pitch.

In order to have a gradual distribution of density or pull over a group of adjacent poles, certain fractional numbers of slots must be used. With certain other fractional numbers it is shown that the poles having high density at a given instant are so alternated with poles of low density that the frame deformation is of a different form. The curves of magnetic pull plotted against pole position in these cases have two or more maximum points but due to the greater rigidity of the frame, a pull of short wavelength is usually unimportant. There may be a small component of pull which has a two-pole distribution, but its magnitude is so much less than in the previous case that there is seldom any trouble from noise.

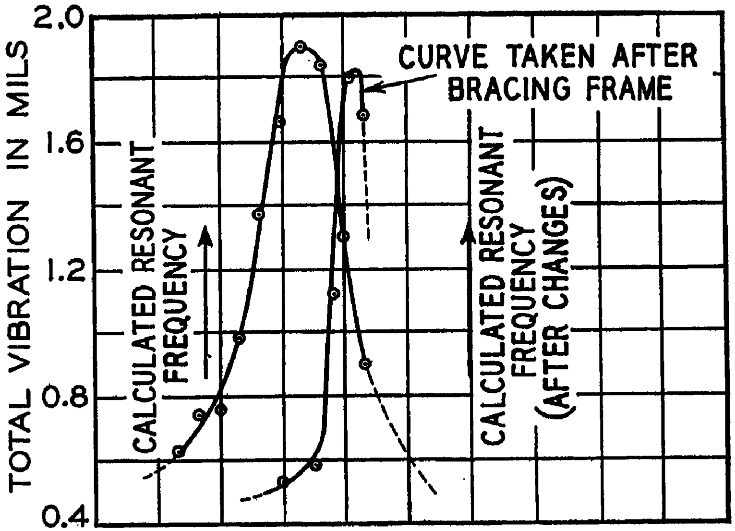

Fig. 2. Resonance curves for pole-frequency stator vibration before and after bracing the motor frame

Pole-Frequency Forces

It has been previously noted[2] that the armature m. m. f. waves of machines having fractional slot windings contain components of low-harmonic order. With certain slot arrangements there may be a component wave of m. m. f. and flux having a two-pole distribution superposed on the main distribution of flux, which will cause elliptical distortion of the stator just as in the case described under no-load noise. In this case the two-pole field travels at the synchronous speed of a two-pole rotor. Similarly, a sub-harmonic having a four-pole (or more) distribution may distort the frame at four (or more) points and cause vibration. In all cases the frequency will be twice that of the supply circuit since the rate at which poles of the superposed distribution pass a given point on the stator is the same regardless of the number of poles.

While it is convenient to start from the assumption of a single two-pole component of armature m. m. f. in describing the effect of a two-pole pull, this simple type does not complete the story. When any two components of flux exist, differing in harmonic order by two, there will be a resulting modulated wave which gives the same effect as a simple two-pole distribution.[3] When the order of magnitudes is examined it is found that these modulated waves are really the important ones since in some cases the several components may combine in such a way as to partly cancel one another, while in other cases they add to form a higher total.

The elimination of any one unwanted harmonic can be accomplished by changing the coil grouping[3] in two relatively simple ways: (1) by cutting out coils the electrical position of which coincides with the vector position of the harmonic to be eliminated; or (2) by shifting coils from one phase group to the next adjacent group in such a way that the troublesome harmonic is

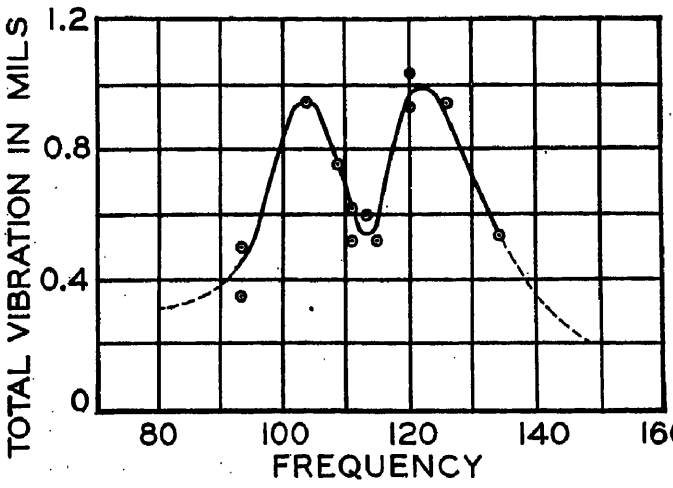

Fig. 3. Resonance for pole-frequency stator vibration showing dip in curv due to an end bell on motor frame

decreased without appreciably reducing the terminal voltage of the machine.

The existence of various forces tending to distort the machine has been established and it has been pointed out that the most serious cases of trouble arise from a two-pole pull which forms a single rotating ellipse since forces distributed in this way produce the greatest deflection. Experience, however, seems to show that nearly all cases of objectionable noise occur when there is resonance between the magnetic forces and some part of the mechanical structure. For this reason even the four-pole (or more) force distribution may result in trouble if the necessary resonant condition exists.

MECHANICAL ASPECTS

It may not be entirely obvious that a rotating deflection of the stator can be affected by resonance; it can be shown, however, that the rotating pull or deflection may be considered as the result of two stationary pulsating pulls which are 90 deg. apart in space and time. Thus resonance to a traveling elliptical deflection is quite possible although in practise one of these components is usually damped to some extent by the frame supports.

Tests made on a number of machines have shown that usually resistance to a distortion in the plane of the laminations is entirely dependent upon the frame or clamping plates and not upon the laminations. The laminations become so much dead weight attached to the frame but add nothing to its stiffness. A formula developed by Timoshenko[4] for simple rings has been applied to complete stators in a number of cases and has given useful results, as shown by the comparison between calculated and test results in Fig. 2.

While it has been shown that stator vibration is of consequence only when there is a force tending toward elliptical distortion of the frame, rotor vibration may be set up also by a periodic variation in the magnitude of the normal radial gap force, such as that occurring in integral slot machines.

Rotor resonance is affected so much by the rotor arms that it is not susceptible to such accurate calculation as the stator. Two formulas,[5] however, one for a section of rim pivoted at both ends and one for a section of rim fixed at both ends, have been found useful in giving the probable upper and lower bounds of resonant frequency for radial vibration.

A formula for the resonant frequency of gears with different modes of rim vibration is also available[6] and has been found useful but requires a great deal of empirical correction when applied to plate spiders.

Tangential vibration of the stator teeth is often throught of as the simplest and most probable form of mechanical vibration causing tooth frequency noise. If it be agreed that resonance is necessary for appreciable tooth motion, then almost all machines are out of the range where tooth resonant frequency approaches tooth frequency. The assumption that resonance is essential is justified by past experience and from a consideration of the stiffness of the teeth appears reasonable.

Results of several vibration tests of machines having pole-frequency vibration are shown in the accompanying illustrations. Measurements were made by amplifying the resistance variations in a phonograph pick-up the needle of which followed the motion of the frame. The accuracy of this method is indicated by the consistency of the test results.

TEST RESULTS

Variation in the amplitude of the vibration at different points around the circumference of a synchronous motor is shown in Fig. 1. (The nodes could be located easily by feeling the frame.) Measurements were made on the back of the punchings half way between the ends of the core. The results, however, would have been the same had they been made at any point on the same axial line.

In Fig. 2 may be seen the change of vibration amplitude as the supply frequency was varied, and the calculated resonant frequency for the motor frame. In making the calculation the punchings were added as dead weight but the armature copper was not included since it is probable that the slot clearance, flexibility of end windings, and damping effect of insulation may cause the effective mass to be zero or even negative. Similar tests were made after the machine was braced to add stiffness to the structure, the results of which also appear in Fig. 2. The reduction in vibration at the operating point (120-cycle) is worthy of note. The frame of this machine was not weak in comparison with frames of similar sizes and types but happened to have a natural period which gave unfortunate results.

In Fig. 3 is shown an exceedingly interesting curve with a dip in the center which was found to be due to end-bell resonance at that point. The violent oscillation of the rather light end-bells absorbed sufficient energy to decrease the frame vibration at what otherwise would have been its region of greatest amplitude. This illustrates the difficulties that face the designer in trying to predict his results, since calculation of the resonant point of a complex structure like an end-bell is practically impossible and since its likelihood of setting up objectionable overtones is great.

Elastic Supports for Rotating Machinery

By
E. H. Hull General Electric Company,
Non-member Schenectady, N. Y.

and

W. C. Stewart General Electric Company,
Associate A. I. E. E. Schenectady, N. Y.

NOISES ORIGINATING from electrical machinery are of two general types, namely, direct air noise, and noise transmitted through the machine foundations to the framework of the enclosing structure. (A. L. Kimball, *Journal of the Acoustical Society*, Vol. 2, No. 2, Oct. 1930, pp. 297-304.) Disturbances of the latter type often may be reduced by a properly designed elastic support between the machine and building.

Elastic supports can be made to isolate two types of disturbance; (1) shocks of any frequency typified by the automobile-spring suspension; (2) vibration of one or several known and constant frequencies. The supports described in this article fall into the second class and their function is to *isolate* not *absorb* vibration.

Effects of such a support may be demonstrated with the apparatus shown in Fig. 1: The mass M constrained to move in a vertical direction is supported through a spring k from the piston P which moves through a constant amplitude in approximate simple harmonic motion; M may be said to be elastically supported. At very low speed the weight moves through the same amplitude and in phase with the driving member. As the speed is increased the amplitude becomes larger, reaching a maximum at critical speed, then reducing as the speed is raised still more. At very high speed the weight appears to stand still in space. From this simple experiment it may be seen that the elastic support is not useful until a speed well above the critical point is reached.

In the case of an elastically supported machine "transmissibility" may be defined as the ratio of the force transmitted to the foundation to the disturbing force impressed on the machine. Fig. 2 shows that an elastic support is not beneficial until the ratio of impressed frequency to natural frequency of the system is greater than 1.41, and that when damping (frictional resistance to motion) is introduced the effectiveness of the support is lessened. See curves marked $b = 0.5$ and $b = 1.0$.

Values of transmissibility, beyond the speed range given in Fig. 2, and with zero damping, are given approximately by the square of the ratio of the natural frequency to the frequency of the impressed force.

MATERIALS AVAILABLE

Of the materials available for elastic support, such as metal springs, rubber, cork, felt, and gelatinous substances, a rubber compound containing a high percentage of pure rubber is at present found to be most suitable. Only small volumes of the material are necessary, the natural life is fairly long, damping is small, and protection from oil usually may be arranged. Once the elastic properties of rubber are understood, supports may be designed for nearly any combination of stiffness.

Noise and vibration of machines which may be transmitted through the foundation, and which may be isolated by an elastic mounting, fall into three general classes:

1. Vibration due to unbalance.

This occurs at rotational frequency which is usually below the audible range and hence does not cause noise directly, but may cause objectionable vibration of the foundations, resulting occasionally in rattles.

2. Bearing and brush noises.

Journal-bearing noise is negligible as is also brush noise in slip-ring motors. Ball or roller bearings may cause an objectionable disturbance.

3. Noise due to magnetic forces.

These forces are the greatest source of noise. In a-c. machines the fundamental noise frequency is twice the applied electrical frequency or 120 cycles for 60-cycle machines. Harmonics of this fundamental frequency and other high frequencies also occur but are of relatively less intensity.

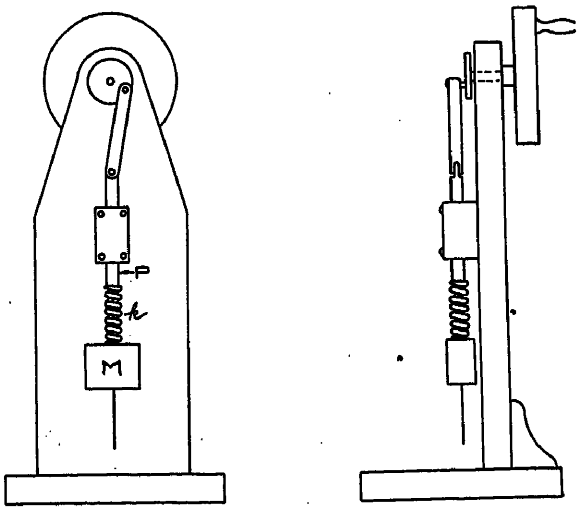

Fig. 1. Apparatus for demonstrating the operating principles of elastic supports

Elastic mountings capable of isolating this noise and these vibrations usually do not constitute a simple system, since in general there are six natural frequencies of the machine on its mounting. Mathematical expressions giving these frequencies have been developed and used to verify and predict resonances observed in elastically supported machines. The elasticity of the mounting must be adjusted to the machine so that none

---

From "Elastic Supports for Isolating Rotating Machinery," (No. 31-76) presented at the North Eastern District meeting of the A. I. E. E., Rochester, N. Y., April 29-May 2, 1931.

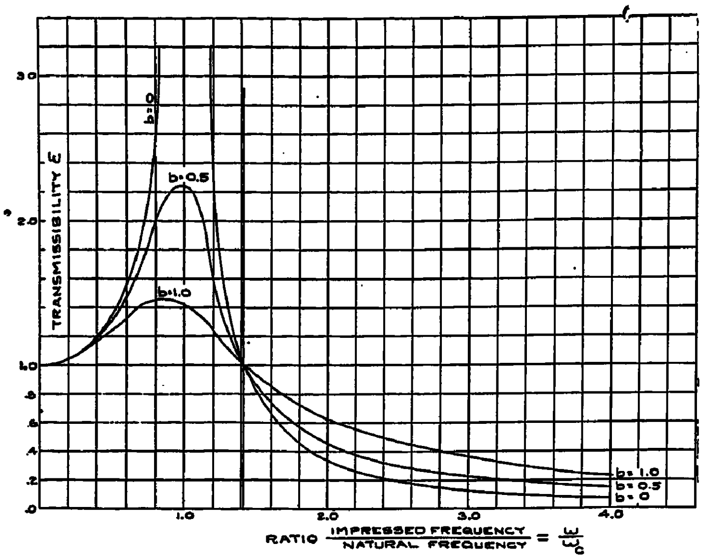

Fig. 2. Transmissibility curves for different damping constants

of these resonant frequencies coincide with that of any disturbing force, for should this occur both the vibration amplitude and the transmissibility would become large.

As stated, there is a wide variety of noise and vibration frequencies to be isolated. It may be shown that if a mounting is designed to isolate a certain frequency, the higher frequencies will be isolated more effectively. For this reason the high frequencies do not present any difficulty unless their amplitudes are greater than those ordinarily encountered.

The foundation upon which a machine is mounted affects to some extent its mounting design. At present, noise problems concern mainly installations in hotels, apartment houses, schools, and office buildings where the foundation is usually a concrete floor. This floor is most sensitive to forces transmitted from the motor in a vertical direction. These tend to bend the floor slab and for this reason the transmitted force normal to the floor should be given particular attention.

Damping is beneficial in the foundation as it reduces the amplitude of the floor vibration which is the source of sound radiation. Since the high frequencies are isolated best by the mounting and are damped most by the foundation, there usually remains as troublesome only the rotational and the fundamental magnetic frequencies.

Elastically-mounted machines may be separated into two classes depending upon whether they (1) transmit torque to apparatus on a separate base or (2) are self contained. Motor-generator sets are of the latter class. Here the stiffness of the support is not limited by the stability of the system against external forces such as belt pull; hence the vertical resonance can be made sufficiently low to isolate the unbalance vibration of the machine, which is the lowest frequency of disturbance present.

RESULTS

A number of motor-generator sets has recently been mounted with marked success on rubber pads. The stiffness of these pads is proportioned to give the set a material frequency in the vertical direction, sufficiently low to insure good isolation. Four pads are usually used, one under each corner of the base.

In the case of polyphase induction motors the magnetic vibration may be in any direction and therefore the stiffness of support for these machines must be low in all directions. On the other hand, the mounting must be sufficiently stiff to withstand belt pull which usually makes it impossible to isolate the low-frequency unbalance vibration. This vibration can be cured at its source, however, by an accurate running balance.

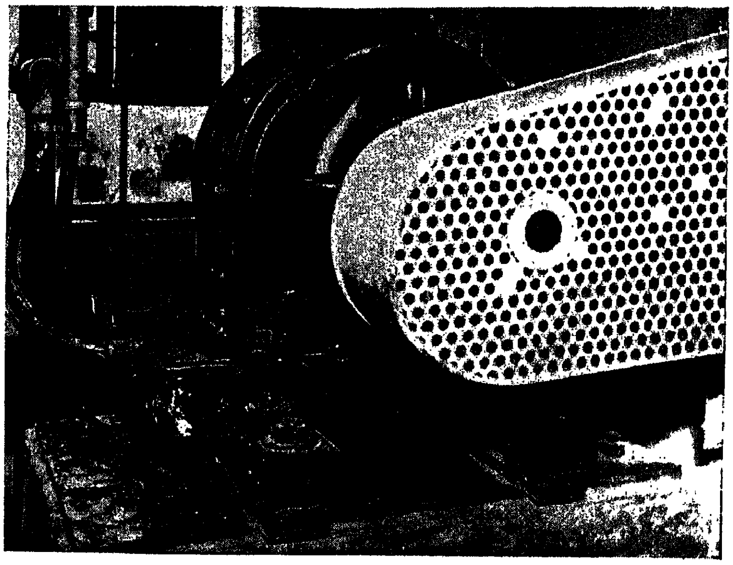

Fig. 3. Induction motor with rubber pad mountings

In Fig. 3 is shown mounted upon rubber pads a variable speed polyphase induction motor used to drive a ventilating fan in a large office building. No noise transmitted from the motor could be detected in the floor. The motor itself was stable throughout the speed range, vibrating through a maximum amplitude of only 0.002 in. at a low frequency due to force transmitted through the belt from the fan. This slight motion however is not objectionable.

This rubber mounting has been compared with all the usual types of elastic mountings by means of a specially prepared sound-box. A motor on the mounting to be tested is placed on top of this box; an observer enters the box and judges the effectiveness of the mounting by the amount of noise transmitted into the box. Results of these tests show that in the prevention of sound transmission the rubber mounting compares very favorably with any of the mountings tested thus far.

The more important results of the investigation may be summarized in the facts that,

1. Elastic supports are useful only when the ratio of the impressed frequency to the natural frequency of the system is greater than 1.41; a ratio of 2 or 3 is sufficient for unbalance vibration, while a ratio of 7 or 8 is necessary for noise isolation.
2. Since it causes increased vibration transmission, damping is undesirable in the elastic member of a support but is beneficial when present in the foundations.
3. If the mounting is designed to isolate low disturbing frequencies, the higher frequencies will take care of themselves.
4. In general, the mounting has six natural frequencies, none of which should occur within ten per cent of the running speed range.
5. For machines which transmit torque, the mounting must be sufficiently rigid in the direction of belt pull to allow stable belt operation.

Measurement of Machinery Noise

By
H. B. Marvin
Associate A. I. E. E.
General Electric Company, Schenectady, N.Y.

MACHINE NOISE INVESTIGATIONS should include vibration tests at various points on the machine and its support, as well as loudness measurements at various points in the surroundings pace. With the "audio noise meter" described in this article, both types of measurements can be made and information thus obtained is extremely valuable in the study of machine noises, their causes and remedies.

For loudness tests, the response of the measuring instrument should correspond with the loudness perceived by the ear. Accordingly a logarithmic scale in which loudness is expressed as the number of decibels[1] (for numbered references see bibliography) above threshold of audibility has been used for the loudness tests involved in this investigation. This choice of threshold or zero loudness as a reference point was made chiefly in order that the results would be comparable with published data on room and street noise.[2]

Reference is here made to a series of contours representing equal loudness which has been set up by Kingsbury.[3] (See Fig. 3 of "A New Meter for Noise Analysis," which appears elsewhere in this series). The contour which at 700 cycles is 30 decibels above threshold of audibility of the average ear has been used as the basis of the response-frequency characteristic of the audio noise meter, for total loudness tests. In the analysis of noise, frequency-weighting by the instrument is not necessary since only one frequency is considered at a time. Thus the loudness of each component is measured separately and referred to the equal loudness contours, a method which gives greatest sensitivity.

DESCRIPTION OF AUDIO NOISE METER

The complete analyzing noise meter is housed in three cases; one contains the measuring amplifier and has space to hold the sound pick-up and tripod; another contains the batteries, while the third contains the analyzer. With this arrangement the meter is portable and may be used with or without the analyzer. Schematic circuit diagrams of all three units are shown in Fig. 1.

The sound pick-up consists of a condenser microphone and a three-stage amplifier enclosed in a separate metal case. Power for the microphone amplifier is obtained from the battery unit.

The amplifier unit consists of a four-stage amplifier with calibrated output meter of the rectifier-milliammeter type, a calibrated attenuator, and an ear-compensation network. Scale and dial are marked in decibels. Tests have shown that over the range of the instrument the readings are closely proportional to loudness.

The analyzer may be connected between the sound pick-up and amplifier to obtain harmonic analysis of noises. This analyzer consists of an electromechanical filter (see Fig. 2) and in order to obtain complete separation of harmonics, it has been designed with high selectivity, yet sufficiently broad at resonance so that small variations of speed or frequency will not seriously affect its operation.

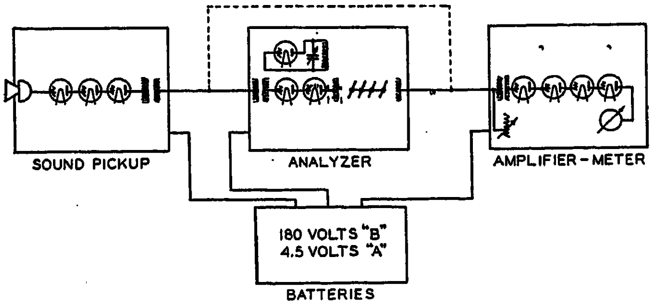

Fig. 1. Schematic diagram of audio noise meter

Complex current to be analyzed is passed through windings on the poles of a driving magnet and a sinusoidal current from a variable-frequency vacuum-tube oscillator is passed through an exciting winding of the same magnet. The resultant flux in the air-gap produces a torque on an armature or vibrator equal in

---

From "The Measurement of Machinery Noise," (No. 31-81) presented at the North Eastern District meeting of the A. I. E. E., Rochester, N. Y., April 29-May 2, 1931.

frequency to the difference between the complex wave and the analyzing sine wave, and proportional to the product of their amplitudes. The armature and its supporting stem are designed to have angular vibration resonance at 6,000 cycles. Four vibrators are tuned to the same frequency and coupled in tandem by wires under tension. A permanent magnet with pole windings is mounted in such relation to the fourth vibrator that the motion of the vibrator induces in the windings of the magnet a voltage proportional to its velocity of angular vibration. Mass and compliance of the vibrators and tension of the coupling wires are adjusted so that the combination has characteristics similar to an electrical band-pass filter.

In operation the frequency of the oscillator is varied slowly from 6,000 to 11,000 cycles. Whenever the difference between this and the frequency of a harmonic in the complex wave equals 6,000 cycles, the analyzer responds. The frequency range is therefore 5,000 cycles maximum, the minimum at present being 30 cycles. This heterodyne method of analysis has the important property of equal selectivity for all harmonics.

CALIBRATION

Laboratory calibration is made by comparison with primary sound standards on sine-wave tones of variable loudness and frequency. The instrument contains voltmeters for checking battery conditions but in addition convenient means are provided for an over-all one-point check which can be made in the field.

In the measurement of vibration a device is held against the machine which generates a voltage proportional to its velocity of vibration. This vibration pickup is substituted for the microphone so that both total vibration and harmonic-analysis measurements are possible. Since the noise is more often proportional to *velocity,* than to *amplitude,* of vibration, this measurement may be used to either supplement or even substitute for sound measurement.

RESULTS

Uses for an audio noise meter are manifold. For some work a total noise test is sufficient, as for example in comparing noise levels in factories or other noisy places, and in the acceptance testing of machinery. If tests are made with the idea of changing design, harmonic analysis is most useful. Fig. 3 shows an analysis of noise from a small synchronous motor in which the noise arises principally from higher harmonics (as high as the 74th) of rotational frequency which is 30 cycles. In synchronous apparatus nearly all noises are multiples of rotational frequency but in induction motors and other variable-speed machines there are usually two series, one based upon power-supply frequency and the other upon rotational frequency.

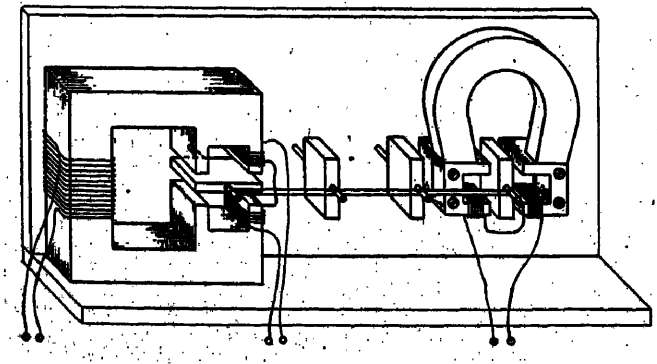

Fig. 2. Electromechanical harmonic analyzer

An analysis of hum from a 325-watt, 60-cycle, 110/1100-volt transformer was made with core clamps loosened, and applied voltage 20 per cent above normal in order to increase the amount and complexity of the resulting noise. Here the harmonics again fell into one series having a fundamental of 120 cycles per second. All harmonics up to the 15th were found to be present in a measurable amount but the fundamental was inaudible. Owing to imagination which would supply a fundamental in order to be logical this would probably not be surmised in a listening test. The effect of loading the transformer was to decrease the total noise, but analysis showed that some harmonics (notably second, sixth, and tenth) were weakened much more than the average.

CONCLUSIONS

Although knowledge of the sense of hearing is still far from complete it is felt that the instrument described serves a very useful purpose in studying machinery noise, the manner of its generation and transmission, and its composition and magnitude.

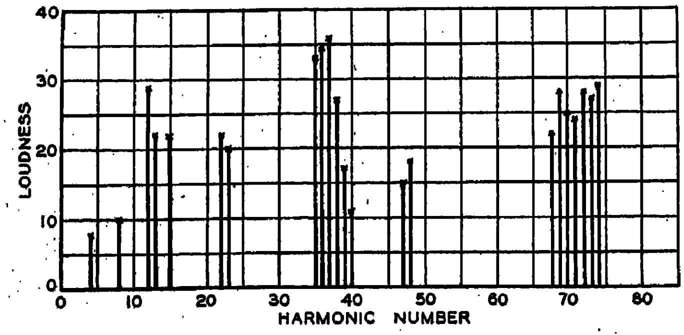

Fig. 3. Analysis of noise from a ¼-hp., three-phase, 60-cycle, 220-volt, 1,800-r.p.m., synchronous motor at no load. The fundamental of the series is rotational frequency or 30 cycles per second

The analyzer has a high degree of selectivity, is convenient to operate and, combined with sound and vibration pick-up devices, enables quantitative analyses to be made on electrical, mechanical, and acoustical waves.

Mitigation of Substation Noise

By
E. A. Bishop
Associate A. I. E. E.
Commonwealth Edison Company, Chicago, Ill.

NOISE REDUCTION IN SUBSTATIONS has in most cases taken the form of confining the noise within certain reasonable limits rather than eliminating it at its source. In accomplishing this, however, other complications are introduced, especially as regards ventilation.

The following classes of substations are discussed in the order named:

1. 230-volt d-c. station located in a downtown district.
2. 600-volt d-c. station for traction service.
3. 1,500-volt d-c. station for electrified railway service.
4. A-c. remote-controlled distribution station.

D-C. Converter Stations

Since the problem of noise due to synchronous converters is common to three of the types of substations mentioned it may be well to discuss it first. Noise emanating from converters is related directly to speed and frequency and in general may be classified as follows:

1. D-c. commutation noise where the brushes riding on the commutator bars and the slots passing under the brushes are contributing factors. High-mica or commutator bars may in addition set up an objectionable chattering noise.
2. Windage, which depends upon the speed of the machine.
3. Magnetic noises which are usually so low-pitched that they are drowned out by other noises.
4. A-c. brush and slip-ring frictional noises.
5. Vibration of the building housing and equipment. This is rather unusual and occurs chiefly if the unit, for any reason, should run on "open phase."

The first measure toward the reduction of converter noise was to provide as a part of the unit a semi-enclosure consisting of a sheet-metal housing with wire glass doors and windows enveloping the d-c. end of the machine. However, when any attempt is made to enclose a converter, a secondary problem of ventilation immediately becomes manifest. In the case of the semi-enclosures this was cared for by leaving an opening in the front end of the housing approximately the same size as the opening inside the commutator. Cool air was then drawn into the armature through the commutator, passed through the ventilating slots of the armature core and windings and discharged through a chimney at the top of the enclosure. In some cases this chimney was connected to a point outside the substation by means of a duct; in others it simply discharged into the converter room. These semi-enclosures effected quite a reduction in noise, but were not satisfactory from either a standpoint of ventilation or accessibility.

The next step was to completely enclose a 600-volt railway converter when the residents in nearby apartment houses objected to its noise. This enclosure consisted of a wall of ½-in. transite supported on a structural steel framework. The inside of this enclosure was lined with 1-in. asbestos hair felt. A baffled chimney on top of the housing permitted the air to be discharged, and deadened a large part of the noise.

From a noise reduction point of view the total enclosure was fairly successful since it eliminated the complaints, but protection against heating was quite a serious problem and required the installation of a blower to force cooling air through the housing. A new problem presented itself when flashovers occurred and small particles of hot copper or carbon were discharged into the hair felt lining. This material did not burn rapidly but due to the draft would smolder, making it necessary to use a fire extinguisher. This was overcome by placing a second lining of ⅛-in. porous asbestos paper inside the hair felt. The net result was satisfactory although the relatively poorer noise absorbing quality of the thin asbestos slightly decreased the over-all noise reduction.

Success in this experiment resulted in the continued development of the total enclosure, which along two general lines is now designed by the two principal manufacturers. The first consists simply of a cubical housing completely enveloping the entire converter, the dimensions being such that the sides are a few inches clear of the machine bedplate at all points. A partition at the main field yoke divides the housing into two sections. Air for ventilation is admitted at the d-c. side of the unit through openings in the foundation, and is discharged through a chimney located in the top on the a-c. side, a blower being required on either the intake or discharge side to circulate the air.

The second design, while completely enveloping the converter, conforms to the general shape of the unit, and is rounded off at the top. The method of ventilation is identical with the first design.

Compared to the semi-enclosures, these total enclosures have the advantages of greater noise reduction,

---

From "Noise Mitigation in Substations," (No. 31-73) presented at the North Eastern District meeting of the A. I. E. E., Rochester, N. Y., April 29-May 2, 1931.

better ventilation, and more space available for maintenance and minor repairs. It should be mentioned, however, that complete disassembly is required for major repairs and due to the elaborate ventilation facilities required an added initial cost is involved.

In a recent installation there arose the problem of noise being communicated to adjacent parts of a large building in which was located a theater immediately over the substation. The following measures were taken to provide a quiet installation:

1. The converters of course were completely housed.
2. Converters and transformers were supported on cork insulated foundations.
3. Blowers and motors were likewise mounted on cork foundations.
4. Connections to the air-exhaust ducts were made with a canvas joint.
5. Flexible laminated copper strips were used for the main d-c. terminal connections.
6. To further eliminate the possibility of vibration being communicated along the main copper connections and in turn through the supports to the building steel, several flexible joints were made in these long runs.

The installation has been in service two years and has proved satisfactory in every way.

At the present time, there is under consideration the problem of noise mitigation in 1,500-volt traction substations. The units installed consist of two 750-volt machines with commutators connected in series. They run at a speed of 600 r. p. m. and give rise to an extremely high-pitched penetrating noise. This noise consists principally of two elements; one due to commutators and the other to windage. It is not considered feasible to totally enclose these units because of the hazards which would result from flashovers. A new form of pole tip has been designed, however, to reduce the whistling noise produced by the field poles but as yet no authentic data are available regarding the reduction of noise actually attained.

Before leaving converting equipment it should be stated that from a noise mitigating standpoint, the mercury arc rectifier is the most satisfactory device so far developed. Its operation is silent except for the hum in the associated transformer and the noise of the rotary vacuum pump. The latter device has been much improved since the original installations and is now satisfactory.

A-C. SUBSTATIONS

In a-c. distribution substations, the character of the noise produced is entirely different, consisting chiefly of hum having a fundamental frequency of 120 cycles which is inherent in transformers and induction regulators. The noise in these substations while not nearly as intense as in d-c. stations is nevertheless somewhat above the noise level of residential neighborhoods. In one substation, this noise was found to be transmitted through building steel to the outside walls and thence to an adjoining apartment house. This difficulty was overcome by placing cork under the transformers and regulators, and replacing the rigid terminal connections with flexible ones.

Transformers installed outdoors in remote-controlled substations have been the cause of serious complaints. As a rule, they are installed in an open court adjacent to the building which houses switching equipment and regulators. In a typical case this court consisted of brick walls along the side and one end with a wire mesh screen at the opposite end; the brick walls contained small openings for ventilation. In this case the major part of the noise was confined to the court by placing sound-absorbing felt over the wire-mesh screen and constructing a roof of sheet-metal arc-shaped sections having the under side covered with sound-absorbing felt. These sections were arranged so as to baffle the sound waves and at the same time permit free passage of air.

In summarizing the situation, at least so far as rotating equipment is concerned, very little has been accomplished toward reducing the noise inherent in the machines. Practically all efforts up to the present time have been toward confining the noise to the equipment and in solving the incidental ventilation problems.

Noise from Induction Regulators

By
J. P. Foltz Associate A. I. E. E. — Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.
and
W. F. Shirk Non-member — Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.

AN IMPORTANT PREREQUISITE to the study of noise in induction regulators is the establishment of a method for making quantitative noise measurements. Surroundings have a very great effect on the values of sound intensity; thus for consistent results all sound measurements should be made under identical conditions as regards not only background noises but also surfaces in the vicinity. Induction regulators, however, are usually difficult to handle and it is therefore quite inconvenient to move them to a place suitable for making sound measurements.

Since surface vibration is the chief cause of noise in induction regulators and since this vibration bears a quantitative relation to the sound produced, many of

---

From "Induction Regulator Noise," (No. 31-84) presented at the North Eastern District meeting of the A. I. E. E., Rochester, N. Y., April 29-May 2, 1931.

the difficulties experienced in making suitable sound measurements can be obviated by measuring vibration instead. Special surroundings are not required for vibration measurements; with a minimum expenditure of time direct comparison of machines is possible on the test floor during working hours. It is possible also to make representative measurements on the various elements of a machine, tracing vibration to its source and determining the effect of different conditions upon that source.

Noise produced by induction regulators and transformers is quite simple in character as compared with noise produced by rotating machinery. The noise (exclusive of clicking of relays during the period of voltage adjustment) has a fundamental frequency double that of the supply voltage and is radiated directly from the tank walls, cooling tubes, and boxes housing the control panels fastened directly onto the side of the regulator. There may be present harmonics of the fundamental depending on the supply voltage, but usually these are not large.

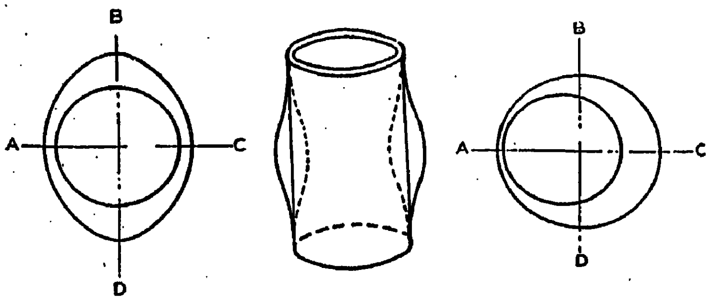

Fig. 1. Illustrating in exaggerated form some factors affecting stator vibration. From left to right, elliptical deformation of the stator by field forces; vibration of stator under radial forces of field; rotor out of center with stator

Experience gained on small single-phase regulators in the past has indicated that invariably noise could be reduced by a well-balanced gap and small clearances in the bearings; however, more recent experience with larger machines has shown that there are several types of vibration (especially in larger regulators) which no degree of accuracy as to mechanical fitting and centering will cure.

According to the source, (See Fig. 1) regulator vibration may be divided under the following three headings:

1. "Hoop vibration" caused by the radial forces set up by the magnetic flux across the air-gap. Since this force is balanced its only effect in the two-pole regulator is to deform the stator into an ellipse with minor axis corresponding to maximum of flux wave. The result of this deformation is a vibration of the stator in a radial direction and is transmitted directly through the oil to the tank.

2. Vibration due to the rotor being out of center or eccentric with regard to the stator. In this case the forces on either side of the rotor are not balanced and there is a resultant force tending to vibrate the rotor and stator as beams supported at the ends. This vibration is transmitted to the tank partly through the top and partly through the oil directly from the stator.

3. Torsional vibration. This is evident in some single-phase regulators, and is carried to the cover through the worm and segment. While this type does not contribute much to the noise directly, if of sufficient magnitude it is liable to cause impact between worm and segment, with a resultant rattle that is quite objectionable.

These types of vibration are all of the same frequency but in any consideration of causes it is necessary to distinguish between them.

The more important type of vibration in large three-phase two-pole regulators is that produced by the elliptical deformation of the stator under the action of the field (hoop vibration). In small machines the stator rigidity is sufficiently high to limit this vibration to a point where the other types of vibration become of importance.

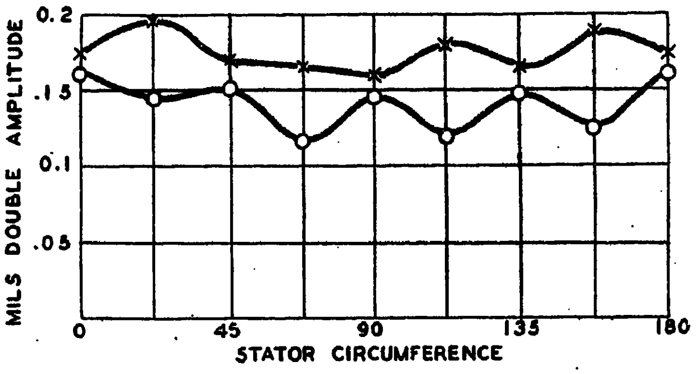

Fig. 2. Relative vibration amplitudes measured on circumference of core (x) and frame (o) of a typical regulator

In designing regulators it is desirable to calculate the probable amount of vibration that will be produced in the finished machine. It is possible to do this approximately by the usual theoretical formula (*Etude Meneanique Et Uswage Des Machines Electriquet,* by H. DePistoye, p. 560) provided certain assumptions and approximations are made.

In the case of hoop vibration the annular rigidity of the stator is the controlling factor so that the amplitude of vibration is the same as the static deflection under the load produced by the force of the field. In a three-phase regulator the field is fairly well distributed but it may be considered as having a sine wave of distribution. For example in a representative three-phase two-pole regulator the double amplitude of vibration was calculated to be 0.14×10^{-3} in. The measured double amplitude on this same regulator (average of several readings) was 0.19×10^{-3} inches.

If the rotor is slightly eccentric in the air-gap the forces of the field on either side of the stator do not balance and the rotor is deflected toward the narrower gap. Vibration having a frequency double that of the supply voltage is set up adding to the hoop vibration on one side and subtracting on the other. The vibration of the rotor is carried to the covers and thence to the outer tank surface. In practise, however, it is quite possible to keep the eccentricity low enough on most large regulators to keep this type of vibration within limits.

Torsional vibrations of the rotor, (due to flexibility in the shaft and worm), are controlled by the mass reaction of the rotor. This type of vibration is not important except in small regulators and large 25-cycle regulators. Torsional vibration does not usually contribute much to the noise directly, but in the worm and segment is a system which has a variable spring constant so that higher frequencies may be introduced due to impact between worm and segment. These lie in the range of greater ear sensitivity and are very objectionable. The introduction of flexibility between rotor and segment or between worm and cover eliminates this difficulty by preventing the vibration from reaching the cover.

While the vibration has its chief origin in the stator core it must pass through the oil before it can affect the tank wall and thus be radiated as sound. The oil is nearly incompressible, however, and thus serves as an excellent medium for transmitting the vibration to the tank. The tank, however, does not follow the core but appears to have on the surface a number of locally resonant regions whose positions are not at all definitely determined. As a result and in order to compare machines, it is necessary to take a number of readings both in a vertical and horizontal plane and obtain an average.

Since cooling tubes are liable to be resonant in themselves their presence further complicates the action of the tank wall. This tube resonance should be guarded against not only on account of noise but because, due to the large amplitudes that occur at resonance, it is likely to fatigue the weld where the tube enters the tank and create an oil leak. In these tubes one may find anything from nearly rigid support to nearly perfect flexibility at end welds. In order to be safe then it is necessary to work outside the region between these two extremes. This resonance region can be computed by consideration of weight of tube full of oil, inertia of cross-section, and length. It is then the problem of the uniformly-loaded beam. Where the tubes are supported one upon another or on the tank at any place other than the end, the problem becomes indeterminate analytically.

With information gained from vibration measurements and some knowledge of the magnetic, electrical, and fundamental mechanical conditions in the general type of structure represented by the induction regulator, it is possible to classify regulator noise according to its source, determine the relative importance of each class in different sizes and types of regulators, and even calculate approximately what to expect from a new design.

Impulse Tests Made on Substations

Unlike many lightning and surge investigations which have largely concerned individual pieces of apparatus, the tests outlined here have been made on complete substation units. Qualitative results have been obtained for two classes of stations.

DURING the past few years a great deal of experimental work has been carried on in studying the nature of disturbances due to lightning, and in determining transmission line characteristics, with a view to forecasting the behavior of transients of this nature on transmission systems. To date, experimental work on terminal equipment has been largely confined to the study of individual units; in the summer of 1930, however, the opportunity to study surge behavior on typical substation layouts presented itself. The tests described were made with the aid of cathode ray oscillograph and portable lightning generator equipment of the Westinghouse Company.

An effort was made to check graphically some of the theories generally accepted in regard to the action of a traveling wave striking typical substation structures, in the expectation that the results might serve to clarify general protection problems. It was realized that actual layouts vary greatly, and that test results must depend largely upon the type of station under investigation; also upon the chosen impulse wave. For these reasons, the results secured are largely qualitative in nature.

These tests were made in New Jersey on the system of the Public Service Electric and Gas Company where

---

From "Impulse Tests on Substations," (No. 31-44) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

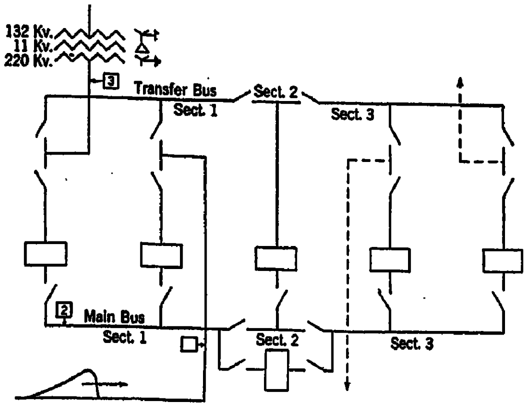

Fig. 1. 220-kv. bus layout at the Roseland substation

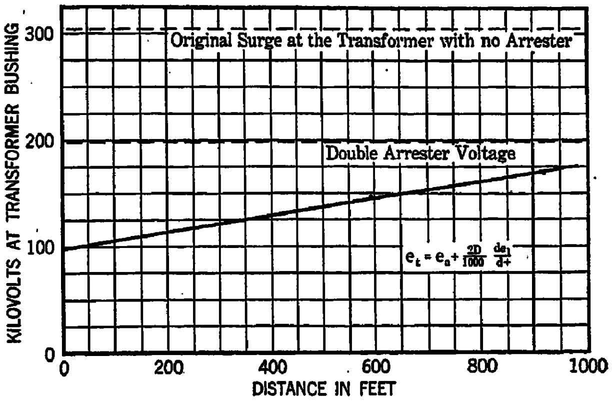

Fig. 2. Variation of impulse voltage at transformer terminals in the Roseland station, as affected by the distance between transformer and arrester

two types of substation structures were made available. The first series of tests was made on the 220-kv. bus and transformers at the Roseland switching station, a typical substation of the high-voltage class; the second, on the structures of the Elizabethport 26.4-kv. distribution substation.

The Roseland station is the terminal point of two 220-kv. interconnections feeding a 132-kv. ring which connects the other switching stations of the system. The 220-kv. structures, while complete, had not yet been placed in service.

A schematic diagram of the 220-kv. bus layout may be seen in Fig. 1. The entire bus, all oil circuit breakers, and one of the transformer banks, were available for connection to one incoming 220-kv. line. To secure a general idea of the distances involved, the conductor length from the terminal of the line to the main bus is about 300 ft. and from the bus to the transformer 330 ft. Main and transfer buses are both 270 ft. in length. The transformer bank consists of three single-phase, 30,000-kva. units connected *Y*-*Y* with solidly-grounded neutral on both 220- and 132-kv. windings.

Surges were set up by means of the portable lightning generator, located at a distance of eight line-miles from the station. This generator was adjusted to give at the station a traveling wave having a crest of 169 kv., a front of 5.5 microseconds, and a time-to-half value of 19 microseconds. A short surge of 4 microseconds in length with a crest of 140 kw. was obtained by chopping the longer wave by sphere-gaps connected to the line near the surge generator.

It was first desired to determine the modification of wave shape at the station as compared with the wave shape with the line end open. For this purpose volt-time oscillograms were taken at the line terminal and at the transformer with the line connected to (1) the transfer bus alone, (2) section 1 of the main bus, and oil circuit breakers, and (3) to the complete main and transfer buses and all oil circuit breakers. The effect of connecting the transformer to the station network was also investigated.

Table I shows the reduction in crest voltage in per cent of the open-end voltage for each of the foregoing conditions. In general, the crest of the transient is reduced as more and more bus is added to the circuit, and connecting the transformer caused a further decrease. It may be noted that the reduction was somewhat less for the long wave than for the short wave, and it is to be expected that a still smaller reduction would result from longer waves.

TABLE I—REDUCTION IN IMPULSE CREST VOLTAGE FOR DIFFERENT STATION CONNECTIONS

	Per cent reduction of crest kv.	
Station conditions	19 microsecond wave	4 microsecond wave
Section 1 transfer bus	4.5	
Transformer connected	11.2	32.0
Section 1 main bus line and transformer breakers	5.6	
Transformer connected	14.0	45.0
Complete main and transfer buses all breakers	24.0	
Transformer connected	35.0	65.0

It was desired also to determine how the distance between the point of location of a lightning arrester and the transformer bushing, would affect the voltage at the transformer. The arresters used for these tests were 25-kv. line-type porous-block units. Oscillograms of transformer voltage were taken for three different locations of the arrester; namely, at the transformer bushing, on the main bus 595 ft. from the transformer, and at the line terminal 920 ft. from the transformer. Results of these tests are shown in Fig. 2. It was found that if only one arrester were connected to a single bus leading directly to a transformer, the voltage at the arrester location will be a minimum; the voltage at any other point will depend upon the arrester's rated voltage, the rate of rise of the traveling wave, and the distance from that point to the arrester. With certain

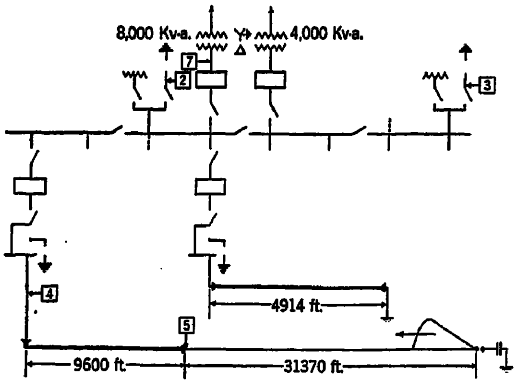

Fig. 3. Layout of bus and lines at the Elizabethport 26.4-kv. distribution station

approximations, the equation of the curve is given by the formula,

$$e_t = e_a + \frac{D}{1000}\;\frac{2\,d\,e_1}{d\,t}$$

where e_t = voltage at the transformer (in kv.)
e_a = arrester's rated voltage (in kv.)
e_1 = crest voltage of traveling wave on the bus (in kv.)
D = distance from arrester to transformer in ft.
$\frac{d\,e_1}{d\,t}$ = kilovolts per microsecond

TESTS AT ELIZABETHPORT SUBSTATION

The Elizabethport substation is designed to receive energy from eight 26.4-kv. cable feeders, and to distribute this energy at 4,150 volts. A schematic diagram of the station layout is shown in Fig. 3. Two of the 26.4-kv. feeders were available for test purposes; also two banks of transformers, the first consisting of two 4,000-kva., three-phase units, and the second a single 4,000-kva. unit. The station bus is about 150 ft. in length.

The line used in the impulse tests extends from the power station for a distance of about six miles in aerial conductor on wood poles to a point 9,600 ft. from the substation, where it enters underground cable leading to the substation bus. In order to secure sufficient distance for establishing a traveling wave effect at the cable pothead, the surge generator was located at the far end of the open-wire line. The cathode ray oscillograph was located at the substation where it could be connected to any point in the outdoor structures.

Connecting bus and transformers to the cable was found to reduce the crest voltage of the waves below the open-end value. A less pronounced modification would be expected here than at Roseland because of the smaller bus capacity and cable impedance. Measurements showed a reduction of only about 5 per cent as compared with the 35 per cent reduction which occurred at the 220-kv. switching station.

In the study of protection to station equipment arresters were placed at three different locations, and the voltage at the transformer measured for each location. Due to limitations on voltage imposed by the insulation of the open-wire line, the maximum test voltage obtainable at the station was about 30 kv. For this reason the arresters used were 6-kv. station type, which had a breakdown voltage sufficiently under the incident crest voltage to secure comparative results.

The arrester locations chosen were (1) the transformer bushing, (2) the main bus 90 ft. distant from the transformer, and (3) the main bus 150 ft. from the transformer. The maximum voltages recorded at the transformer for these positions of the arrester were respectively 21, 23.5, and 25 kv. From these results it is obvious that the problem of properly locating arresters in a station of this size is relatively simple.

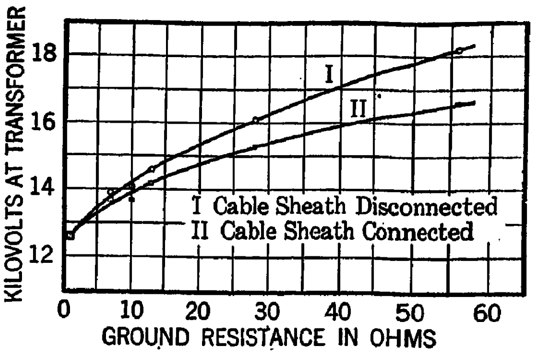

Fig. 4. Impulse voltage at transformer terminals in the Elizabethport station with arrester located on open line at various distances from the cable pothead

Another problem under investigation at this substation was to determine an effective arrester location for a point outside the station, at or beyond the cable pothead. The locations chosen for test were at the pothead itself, and at several points on the open wire at distances of from 300 to 3,300 ft. from this point. Arresters used were of the 6-kv. line type as before. Ground resistances at this location were quite favorable varying] in actual value from only about 0.5 to 1.5 ohms.

Results of these tests may be seen in Fig. 4. Due to the decreased conductor surge impedance at the cable pothead, the voltage at this point was insufficient to cause the arrester to breakdown. It may be noted that the impulse voltage at the station decreased as the arrester was moved away from the pothead, the slope of the curve decreasing considerably at about the 1,000-ft. point.

SUMMARY

Summarizing the more important results of both series of tests, it can be said that:

1. The capacity to ground of the bus and circuit breakers in large substations tends to reduce the impulse terminal voltage. In general, the effect of connecting transformers to the bus system is a further sloping off of the wave-front and reduction of the crest. The total effect is more pronounced in the case of very short waves, but appears to be appreciable for those of even moderate length.

2. When lightning arresters are placed on the bus, the voltage at the transformer will be greater than that at the arrester by an amount depending upon the steepness of the lightning transient, the arrester breakdown voltage, and the circuit distance from the arrester to the transformer. Oscillograms show results in agreement with calculations. For any given arrester location the seriousness of such over-voltages decreases with increasing arrester-voltage rating. For minimum impulse voltage, the arrester should be connected to the transformer bushing.

3. Because of the low terminal capacity and low surge impedance of entering feeders in small substations fed by cables, the capacity of the bus and connected apparatus causes only a relatively small decrease in the impulse-terminal voltage.

4. When a lightning arrester is placed on an aerial line joining a long cable leading to a substation, the station protection for a surge originating beyond the arrester is increased as the arrester is moved away from the junction along the open wire. This increase in protection is greatest for the first 1,000 ft. the arrester is moved out from the pothead. The exact arrester location must be selected also with due consideration to the possibility of a lightning stroke between the pothead and the arrester.

5. High ground resistance is found to decrease materially the protective value of line arresters; where this condition exists, arrester performance can be improved by connecting the high-resistance ground directly to the cable sheath. Economic considerations will decide where such a measure should be adopted.

Artificial Sunshine for the Modern Office

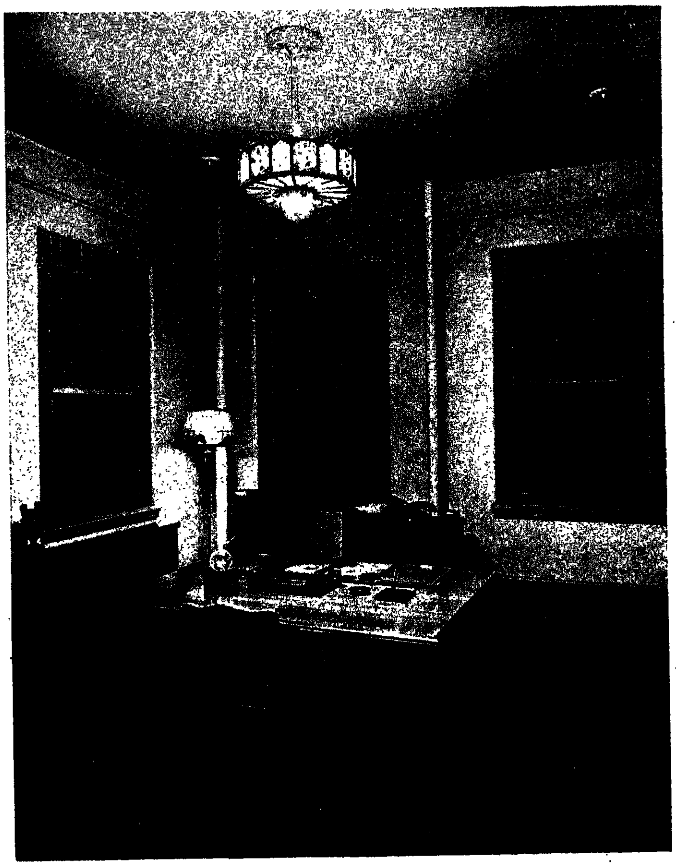
OFFICE SUNSHINE is provided by a special dual-purpose ceiling fixture recently designed for his office by M. Luckiesh, director of the General Electric Company's lighting research laboratory at Nela Park, Cleveland. A similar fixture is installed in the office of the president of the Cleveland Electric League.

These pioneer dual-purpose luminaries supply approximately 80 foot-candles on the desk top without creating a feeling of "too much light." Relatively few offices have artificial light intensities even as high as ten foot-candles and offices with 30 foot-candles are rare. The lighting shown is pleasing and comfortable, and the ultra-violet radiation has the same health-maintaining characteristics as outdoor summer sunshine.

This particular lighting fixture has an upward or indirect lighting component supplied by eight 100-watt incandescent lamps equally spaced in the upper portion connected to two circuits. This alone supplies a general illumination of 10 foot-candles. The downward component of light and the ultra-violet radiation are produced from one "sunlight" lamp (S-1) in the center of an oxidized aluminum reflector equipped with baffle-rings which control the light distribution and ultra-violet radiation and which shield the eyes from direct view of the S-1 lamp.

Like the portable sun lamp, this fixture necessitates the use of a transformer, and in this particular unit it has been conveniently located in the ceiling directly above the canopy.

In buildings where the space between floors will not permit the recessing of a transformer, it is possible to run heavy wires from the fixture to a point convenient for the location of the transformer. This wire should not be smaller than:



Eighty foot-candles of healthful light on the working plane in this office

No. 10 B & S gage for distances up to 15 ft.
No. 8 B & S gage for distances up to 25 ft.
No. 6 B & S gage for distances up to 40 ft.
No. 4 B & S gage for distances up to 60 ft.

Like the studios of the National Broadcasting Company in Chicago where ultra-violet radiation is supplied from overhead units, these office fixtures are creating much interest in the minds of all who have had the opportunity to see them.

Automatic Arc Welding

By the use of arc welding, marked savings have been effected in the manufacture of electrical apparatus. Automatic control for this process has made possible still greater savings and at the same time better and more uniform products.

By G. H. Koch

General Engineer
Westinghouse Electric & Manufacturing Company

ARC-WELDED PRODUCTS and their many advantages over the castings and riveted structures, which they superseded, have been discussed quite thoroughly in various recent publications. The manufacturers of electrical machinery were among the first to take advantage of the flexibility and liberties of new design afforded by the arc-welding process. Automatic control is now being applied to this type of welding and the great saving of time over that required for hand operation is resulting in lower production costs for parts so manufactured.

Where manual welding is employed, the trained welder replaces the trained foundryman or the skilled riveter in obtaining the final results. In both the old and the new processes, then, the quality of the product is as much dependent upon the care and vigilance of the artisan in overalls as upon the judgment and slide rule of the designer. The functions performed by the trained welder were found to be particularly suited to reproduction by machinery. The arc voltage must be maintained at a constant value and the electrode feed towards the arc should be as uniform as is consistent with a constant arc voltage. The progress of the arc along the seam should be steady and at a fixed rate.

In an automatic arc-welding machine an electric motor is used to feed the electrode at the required rate to maintain a constant arc voltage between the electrode and the work. A machine of this type is shown in Fig. 1. As may be noted, the electrode passes through a long nozzle after it leaves the driving rolls and emerges at the lower end to be fused in the arc and deposited on the work. Welding current enters the electrode through the sliding contact in the nozzle.

Elements sensitive to arc voltage automatically regulate the direction and speed of the welding electrode and serve to maintain the arc voltage constant even on an irregular surface. Separate motor-driven devices provide a uniform motion of the arc along the seam and a weaving motion across the seam where this is desired. After the current value, arc voltage, and travel speed are selected for a given job, the operator is required only to start and stop the welding operation, and to change the work. In some high-speed production work even these operations are performed automatically.

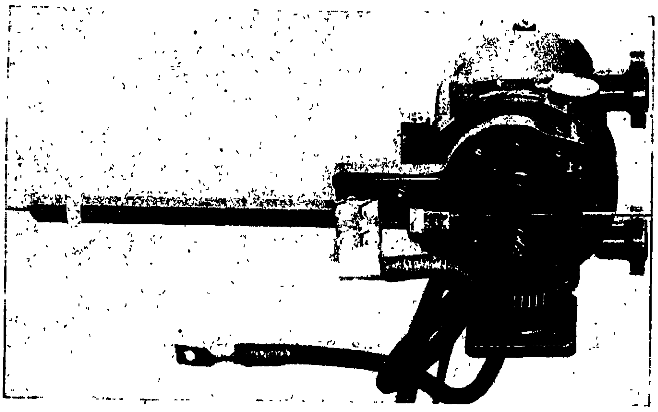


Fig. 1. Automatic welding head showing electrode feed mechanism

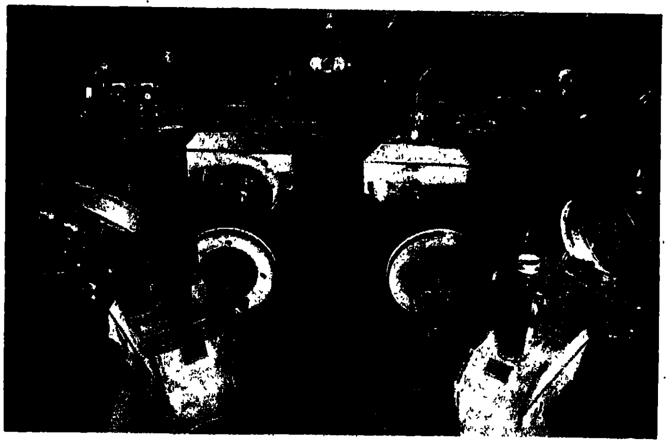

Fig. 2. An installation of four automatic welding heads for building up worn car-wheel flanges

As a general rule on any given job only slightly larger electrodes are used for automatic welding than for hand welding. Increased welding speed is brought about largely by the fact that a higher current density in the electrode is possible in automatic welding than in hand welding. About 25,000 amperes per sq. in. of electrode section is common in automatic welding compared with 10,000 amperes per sq. in. in hand welding. This increased current concentration provides for better fusion and improved arc stability. Usually less deposited metal is required in automatic welding because

---

From a paper presented informally at the A. I. E. E. Southern District meeting, Louisville, Ky., Nov. 19-22, 1930.

of this factor and because of the greater general reliability. Furthermore, since the electrode is fed continuously from a reel, there are no interruptions such as the manual welder introduces in changing electrode rods. All of these factors tend towards increased speed and better welds.

The comparative welding speeds for automatic and manual arc welding are now fairly well known for existing commercial electrodes. In general it may be said that simple, continuous welds may be made with an automatic welding head in from one-third to one-sixth of the time required by an expert manual welder, depending upon the thickness of material.

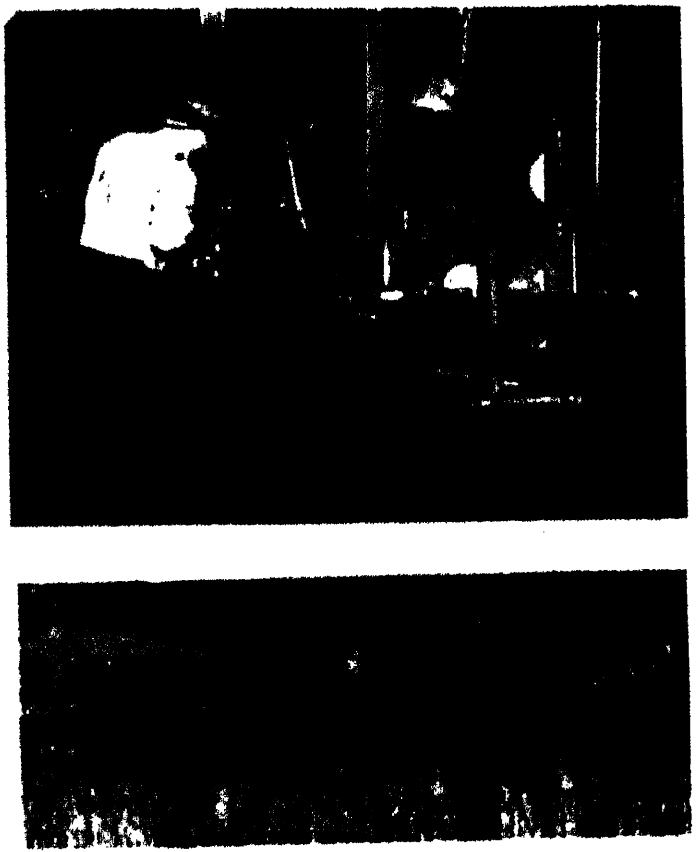

Fig. 3. Special clamp (above) for holding tank sheets and tubes during welding process. Note thickness of material in finished weld, (below)

One of the earliest applications of automatic welding in the electrical industry was in connection with the repair of worn flanges on steel street-car wheels. Unless the worn section is built up by welding, an excessive amount of material must be cut from the face of the wheel to restore the proper face contour. An installation of four automatic-welding heads in a large street railway repair shop is shown in Fig. 2. One man can keep the four automatic arcs in operation, thereby doing the work of twelve manual welders. The automatic weld sets up much lower shrinkage stresses in the wheel than a manual operation since a large number of beads are added successively at a relatively high speed thereby providing uniform heat distribution.

Automatic welding next was introduced into the manufacture of sheet-steel tanks for transformers and circuit breakers. A seam-welding clamp used to make longitudinal butt and lap welds in round, elliptical, or rectangular tank shells is shown in Fig. 3. A large shell or a number of small ones is held against a backing bar by air-pressure clamping fingers and the weld is made by the automatic head which is mounted on the traveling carriage. Mounted also on this carriage are the electrode reel and operator's controls. The carriage is self-propelled at any desired welding speed on a trackway built integral with the air clamp frame.

With this apparatus an oil-tight, reenforced butt weld can be made on 5/16-in. steel at a rate of 20 ft. per hr. without beveling or otherwise preparing the edges. This type of weld is reenforced on both sides; it also must pass rigid inspections for appearance as well as for strength and density, and for these reasons is often made in two or more passes. Such a weld can not be duplicated by an expert manual welder at a speed greater than 6 ft. per hr., using commercial electrodes. It is thus evident that the use of the automatic welder in this case results in a time saving of about 70 per cent. On lighter plates this saving would be still greater.

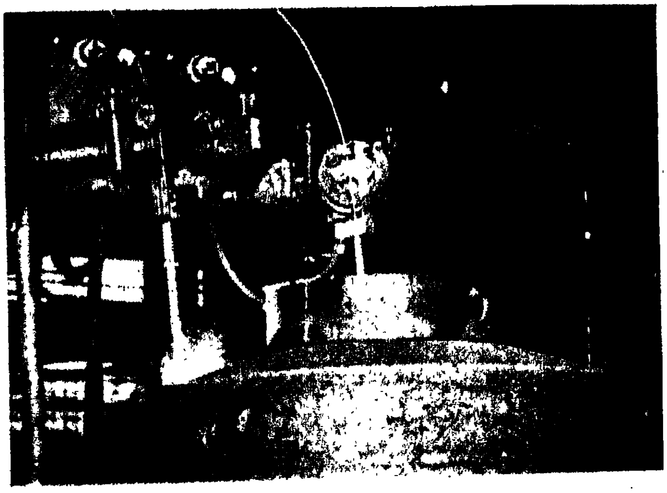

Fig. 4. Welding end plates in a circuit-breaker tank showing two automatic heads in operation.

A method for welding bottoms in cylindrical circuit-breaker tanks is illustrated in Fig. 4. The shell is centered on a turntable flush with the floor level and is rotated under the arcs held by two automatic heads. In this way the bottom of a 42-in. diameter tank with a 5/8-in. wall thickness is welded in 18 min. by a single operator as compared with the 2½ hr. required by a manual welder to complete the job.

With the recent advent of electrical machinery frames fabricated from structural members and plates welded together, automatic welding received another impetus. A machine especially developed to weld short, straight seams such as would be encountered in this type of work is shown in Fig. 5. In this device the welding head is mounted on an arm which reciprocates along the joint at welding speed. The wire reel and operator's control are mounted on the base of the machine so that the entire unit may be moved to a heavy piece of work within the radius of the supply cable reach.

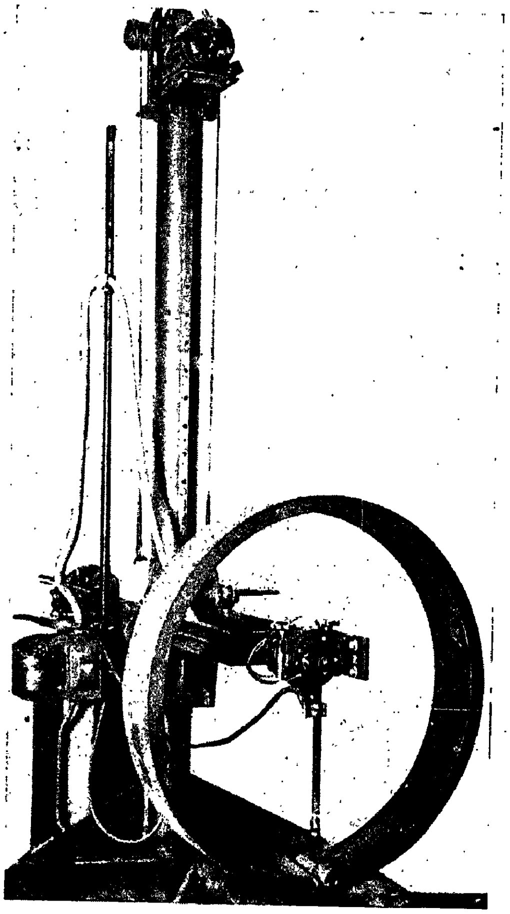

Fig. 5. Machine for making short, straight welds. A structural-steel motor frame may be seen, set up for processing

For heavy fillet welding it is necessary to tilt the work to obtain the most satisfactory results. This is especially true of plates greater than 5/16 in. in thickness for a full-strength fillet. A machine designed to accomplish this purpose is shown in Fig. 6. Tilting the work in this way permits maximum welding current and metal deposits and results in a normal fillet similar to that produced by an expert hand welder with proper manipulation.

Automatic welding is not by any means limited to heavy welds or large joints. As a matter of fact, the time saving over manual welding is much greater on thin sheets and small beads. With a special machine designed for this service certain welding operations now are performed in 45 sec. which required 7 min. for manual welding. In this case, the welding speed was 140 ft. per hr. However, a speed of 200 ft. per hr. could easily be obtained with increased welding current, but would result in a slight sacrifice in appearance.

Another interesting application of automatic welding is in connection with the manufacture of textile motors. The service requirements of these motors demand extraordinary strength and sturdiness for protection against vibration and uneven torque load. As may be seen in Fig. 7, the stator punchings and end-rings for the bracket fits are made integral by welding four angle plates across from one end-ring to the other with a fillet weld at each plate edge. These eight welds are made while the parts are held together in a jig after removal from the assembly press. As a result both the punchings and end-rings are individually welded

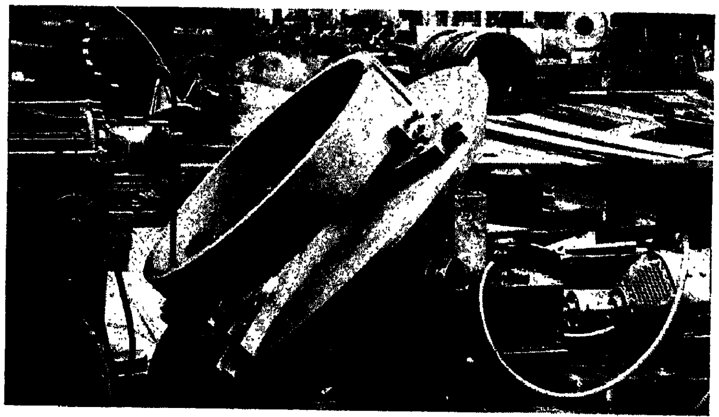

Fig. 6. Machine used in tilting heavy pieces for fillet welding

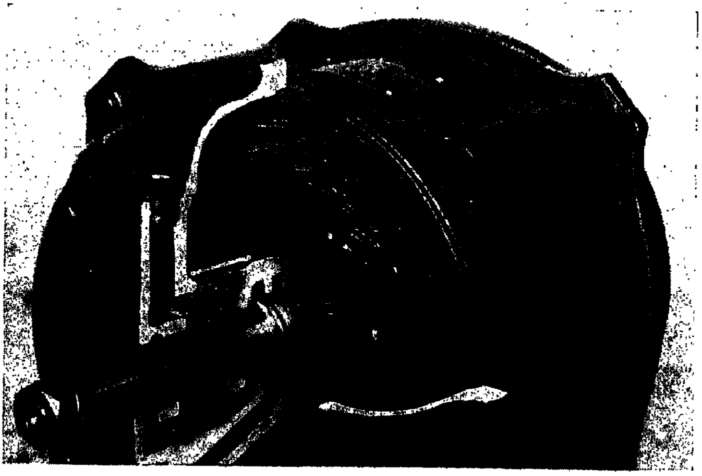

Fig. 7. Section of textile motor assembled by automatic welding. Note that laminations and end rings are held together by fillet-welded angle plates

to the angle plates and are held together under assembly pressure.

The saving in welding time affected in each of the applications illustrated give a good indication of the possibilities of the automatic-welding head in leading the way to new production economies. Provided apparatus is included to limit the handling time in changing the work, and provided such apparatus can be installed at reasonable expense, nearly every production welding job from an economical point of view, is open to automatic welding. In some applications, handling time is unavoidably the bulk of the welding time; in such cases, automatic welding can still be considered advantageous on account of its improved and consistent results.

Percentage-Differential Transformer Protection

Three-winding transformers present difficult problems for the protection engineer. Differential relays which operate on the phase difference between the currents in the different windings are particularly adapted to meet the requirements.

By R. E. Cordray

General Electric Company
Philadelphia

PROTECTION of three-winding transformers became a problem for serious consideration shortly after the introduction of this type of transformer a few years ago. The special requirements of these transformers necessitated that any suitable scheme of protection in case of an internal fault must remove the transformer from all three of its associated circuits simultaneously. In addition, an external fault on any one of its associate circuits must be cleared without putting the transformer out of service. Differential relays which operate on the phase difference between the currents in the different windings are particularly adapted to meet these requirements.

Occurrence of an internal fault in a three-winding power transformer requires the complete isolation of the transformer in the shortest possible time. In addition to this requirement, the protection must carefully discriminate between internal and external faults such as those occurring on associated transmission lines. It would be desirable of course to have the protection sufficiently sensitive so that it would function on the least possible fault; as for example, one between adjacent turns. Among other factors which affect the sensitivity are possible false operation and economy of winding replacement. However, assuming that the protective relays would operate instantaneously even a turn-to-turn fault would probably damage several turns or even a whole section of the winding before the circuit breakers could open.

Probability of a ground fault inside a transformer—that is, a fault between the winding and the core—is becoming more remote as the design of transformers continues to improve. A feature of one modern design for medium and high voltages is the complete covering of the iron core with a cylinder of very heavy insulating material, and the separation of the different voltage windings by similar insulation. For the same reason faults between phases are also becoming scarcer. Consequently, the problem consists principally of protecting against faults between turns or parts of the same winding.

PERCENTAGE DIFFERENTIAL PROTECTION

Differential protection of three-winding power transformers, as mentioned in the beginning, operates on the vector difference of the currents flowing in and out of the transformer. This protection is theoretically free from the effect of external faults, because, neglecting the exciting current, the vector difference between these currents is zero except at the time of an internal fault.

Practical application of this theory has been accomplished by connecting in parallel the secondary windings of all the current transformers in each phase, providing their ratios are such as to exactly compensate for the different voltage ratios of the power-transformer windings. In practise, such differences as do exist are easily compensated for by using auxiliary autotransformers in the current-transformer secondary circuits.

Unfortunately current transformers do not in general maintain the same ratio characteristics up to many times their full-load rating. This performance characteristic is aggravated by the current transformers being generally of different types, with one set frequently of the bushing type. This difficulty is overcome by using the percentage differential principle.

Percentage differential characteristics are in effect an automatic means of raising the setting of the relay at the time of a through fault. This automatic raising is obtained by having elements in the relay energized by the through currents; that is, by the current in each of the power-transformer windings. These elements act to oppose the torque of the operating element actuated by the "difference" current. By proportioning the number of turns in these windings it is possible to secure relay operating characteristics having any percentage desired.

Connections required for a typical relay installation of this type are shown in schematic form in Fig. 1. The relay shown here provides a separate restraining torque from each of the three power-transformer windings. Current values for torques so proportioned that the operating-coil current is 25 per cent of the average restraining or through current are shown in Fig. 2. In actual practise this proportion is set sometimes as high as 50 per cent.

A great advantage of this percentage characteristic is that it can be used on power transformers with voltage taps, even where taps are automatically adjusted to meet load conditions. In Fig. 2 is shown the "difference" current which exists when the bank has 10 per cent buck or boost taps in addition to the 25 per cent differential relay characterics. The protection afforded the power transformer is practically the same regardless of whether taps are at the zero, maximum buck, or maximum boost position.

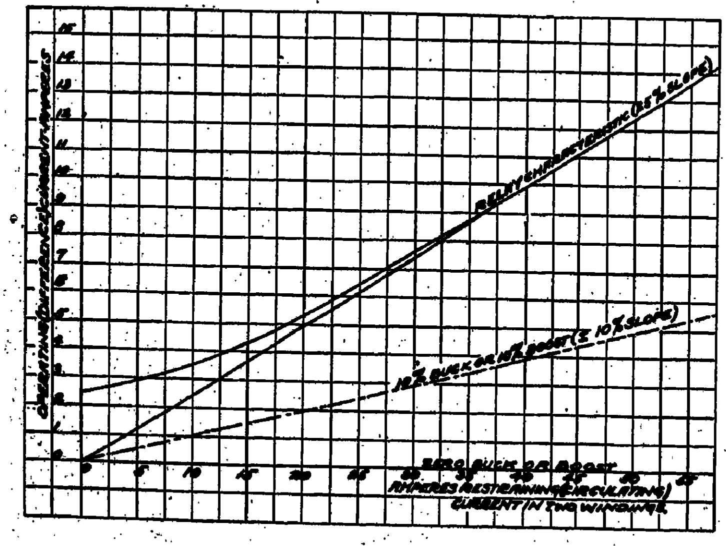

Fig. 2. Relay characteristics for 25 per cent differential protection

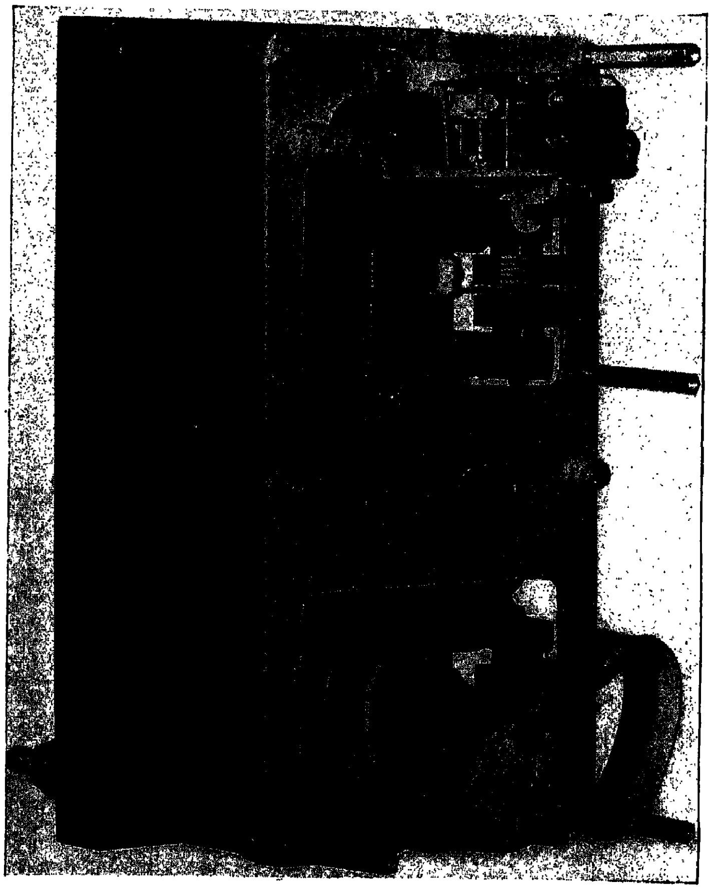

Fig. 3. Front view of differential relay with cover removed

EFFECT OF MAGNETIZING CURRENT INRUSH

Control springs for adjusting the minimum operating current are provided on these relays and are similar to those found on induction-type overcurrent relays. Minimum-current settings are determined by the probable inrush of magnetizing current to the transformer. In general, the magnetizing current is of the order of only 5 per cent of full-load current; but at the instant of energization, an inrush of transient magnetizing current generally results.

Calculations and actual tests show that the peak of this inrush of magnetizing current can be as much as eight to eleven times the full-load current rating of the power transformer (about 200 times the normal exciting current) and that this current may remain *greater* than full-load value for a relatively long time—30 to 60 cycles on a 60-cycle system.

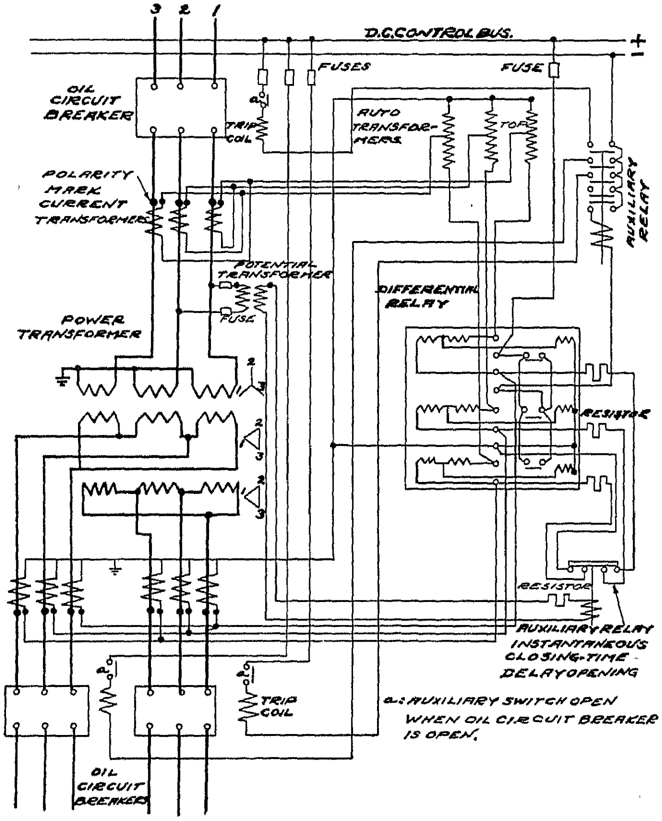

Fig. 4. Complete wiring diagram for percentage differential protection; note potential transformer and auxiliary relay for raising main relay setting during magnetizing current inrush

Relatively high current settings therefore are required to prevent relay operation during these magnetizing transients. One plan of solving this difficulty consists of using an additional relay to momentarily raise the differential-relay setting to a higher value when the power transformer bank is first energized. This relay is operated from a potential transformer placed across any one of the power-transformer windings inside the oil circuit breaker connections. While the power transformer bank is de-energized, the voltage-relay contacts connect a resistor in parallel with the operating coils of the differential relay, thereby raising their current setting. When the transformer is energized, the voltage relay operates after a predetermined time delay, thereby disconnecting the parallel resistor from the differential relay after the cessation of the magnetizing-current transient.

A complete wiring diagram for a typical percentage differential relay installation is shown in Fig. 4. This diagram shows also the connections for the voltage relay just described.

Automatic Speed Regulation

Automatic regulators to be suitable for industrial use must be quick in response, sturdy in construction, require a minimum of maintenance, and be adaptable to a wide variety of applications. How one of the newer types of carbon-pile regulators meets these exacting requirements is outlined in some detail.

By J. H. Ashbaugh

Associate A. I. E. E.

Westinghouse Elec. & Mfg. Co.
East Pittsburgh

ACCURATE speed control constitutes one of the biggest problems confronting the regulator engineer and one of the most important phases of regulation in industry. It is important because every progressive industry is striving to improve its products and to reduce manufacturing costs.

The increasing use of individual motor drives has done much to improve quality, increase production, and reduce costs. However, this same trend has made regulation a more important problem because in many processes the individual motors must be closely and accurately controlled.

Certain applications, such as galvanizing machines, continuous rod and strip mills, and sectional paper-machine drives, require practical synchronization of several motors, and at the same time necessitate a wide speed range. These conditions demand the use of d-c. motors which generally operate from a variable-voltage supply with individual regulation for maintaining a

---

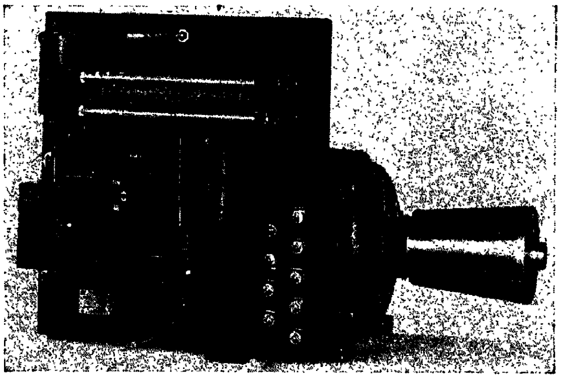
From "Automatic Regulators in Industries," (No. 31-36) presented at the A. I. E. E. winter convention, New York, Jan. 26-30, 1931.

synchronized, but adjustable, relation between motors. Speed regulation of d-c. motors to make their characteristics simulate those of synchronous machines, even under highly fluctuating load conditions, now is an accomplished fact.

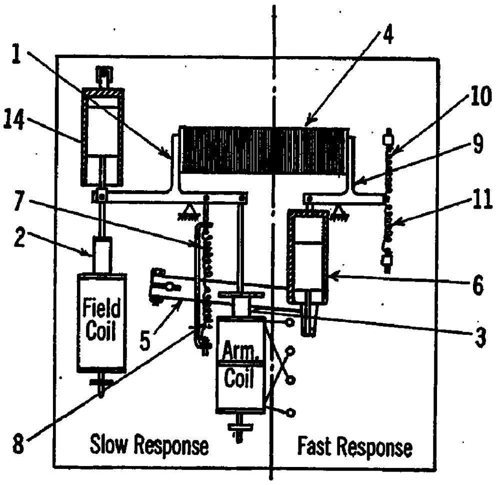
Carbon-pile regulators for this service are extremely simple and exceedingly sturdy. They are capable of field forcing or over-regulation, have effective anti-hunting characteristics, and use no contacts in the controlled circuit.

One of the newer types of carbon-pile regulators is shown in the accompanying illustrations, and may be seen to consist essentially of an electrical unit and a mechanical unit. The mechanical unit is merely a differential, consisting of a worm and nut, a clutch, and a lever system. The unit is made integral with a small synchronous motor which has a hollow shaft through which passes an internal shaft, one end of which drives the differential nut through the friction clutch, the other end being attached to a cone pulley. With the regulator motor driving the worm and the regulated motor driving the cone through a belt, any angular displacement occurring between the two is transmitted directly to the electrical unit which acts immediately to correct the undesired change in the regulated motor.

Characteristics of the electrical unit are such that should the aforementioned angular displacement occur rapidly, the electrical element will respond quickly; but if the change is slow, the correction will be correspondingly slow. As may be seen from the accompanying sketch, the pressure applied to the carbon-pile is varied by the differential lever (5) through the dash-pot (6) and two springs (7-8). The carbon-pile, of course, is connected in the field circuit of the motor to be regulated; two coils are connected to lever (1); coil (2) is in series with the field of the motor, and coil (3) is energized from the interpole. These coils stabilize the regulator and prevent hunting.



Front view of carbon-pile speed regulator for a d-c. motor



Schematic diagram of carbon-pile regulator showing mechanical parts

When a large angular displacement occurs lever (5) moves rapidly, transmitting power momentarily through dash-pot (6) to vary the pressure on the carbon-pile (4). The two springs (10-11) gradually return the dash-pot and lever to a neutral position. The sudden change in field and armature strength causes coils (2-3) to move in such a direction as to anticipate the return to normal conditions; they exert a force on the other end of the pile by deflecting springs (7-8). Dash-pot (14) merely stabilizes the lever and coil inertia. When a slow, angular deflection takes place dash-pot (6) is not moved because the air in it seeps out through an adjustable vent hole. Lever (1) is deflected by varying springs (7-8), resulting in suitable change in pressure on the carbon pile.

This regulator gives a d-c. motor the same characteristics as a synchronous motor. In actual service on a 150-hp. 900-r. p. m. motor the device completely restored and stabilized the speed within three seconds after the instantaneous application of 100 per cent load on the motor.

Considering the broader aspects of the subject, regulators may be divided into three classes; mechanical, hydraulic, and electrical. The progress of development has been in the order named, but because of the flexibility of electrical regulators they soon greatly predominated. In order to prevent surging of the quantity regulated an electrical regulator of course must have incorporated in it the same fundamentals (although in a different form) as the mechanical or hydraulic regulators. This involves careful consideration of the inertia of the system to be regulated and the precision of regulation desired.

In addition to industrial speed regulation, it is possible to effect the close automatic regulation of voltage, load, power factor, pressure, temperature, and many other quantities of importance to the modern industrial concern.

The future of regulators appears to depend largely upon the electron tube. This device is in its infancy but is thought to offer great possibilities in the elimination of moving parts and through its greater sensitivity.

Interchange of Industrial Power for Better Operating Efficiency

Large industrial establishments usually are interconnected with electric utility systems for the purchase of power; but free interchange of electric power between the two is not nearly so common as the economies involved would substantiate. The author recommends unrestricted interchange for the best economy in both systems.

By
*W. B. Skinkle**

Engineer, Pittsburgh District Power Committee,
Subsidiary Companies U. S. Steel Corporation

FREE INTERCHANGE of electric power between large industrial establishments and electric utility systems offers attractive economies to both parties in spite of inhibitions to the contrary. Interconnections are common, of course, between industrials and utilities, but usually the contracts covering such interconnections are narrow and rigid rather than flexible, and usually provide definitely for (1) the utility to furnish all the power; (2) the utility to furnish a certain stipulated base load; or (3) the utility to furnish stipulated peak power and emergency energy. However, numerous engineering analyses and an increasing amount of practical operating experience show that the greatest economies to both parties are realized through unrestricted interchange of power wherever the industrial has large quantities of either by-product or very low-priced fuel available in a form that is not economical to store.

The possibilities of power interchange between utilities and industrials open up a vast field of industrial economics; however, because of an almost unlimited number of special conditions which surround and limit each point of connection, and because industrial conditions are subject to radical and almost momentary change, too often these opportunities for power interchange are given up as impossible because of their involvement. True, such changing conditions do introduce a handicap to the drafting of sufficiently flexible contract agreements, but if both contracting parties will recognize the critical and essential fact that both parties must benefit financially from an interchange agreement, many common difficulties practically dissolve themselves. An interchange agreement should be sufficiently flexible to permit the industrial to draw power from the utility as required and deliver power to the utility whenever a surplus of low-priced fuel is available.

It naturally follows, of course, that the prices for the various kinds of power interchange should be fixed at a rate that will permit any of the classifications of power to be profitably sold by one party, and profitably purchased and absorbed by the system of the other party. Analyses of the interchange problem show that five different classifications of power may be involved in any interchange agreement between a utility and an industrial:

1. Firm power sold by the utility at any time and in any quantity up to the limit of either the contract or the equipment.
2. Surplus power available from either system by reason of surplus generating capacity, idle and awaiting growth of the system on which it is installed.
3. Off-peak dump power.
4. On-peak dump power. Dump power of either classification is power available in the industrial system by reason of surplus by-product heat or fuel which does not lend itself to practical or economical storage.
5. Lastly and most important, the emergency power available from either system to the other on short notice in case of sudden and unforseen operating emergencies.

All of these different classes of power have radically different costs to the producer and radically different values to the purchaser. A mutually acceptable determination of these factors is not extremely difficult to arrive at, and certainly forms a sound basis on which to write a mutually profitable interchange contract.

From the standpoint of the industrial establishment having available an appreciable quantity of heat energy or by-product fuel which is lost unless converted into electric energy and dumped onto the utility system, the conversion of this into electric power is accepted as the logical step. This presupposes the installation of generating equipment capable of absorbing the by-product energy and capable also of carrying some portion of the plant load. In the course of normal operation it is but natural that plant electric power requirements and plant production of by-product heat or fuel may be anything but well synchronized, with the result that at one time there will be more plant-generated power available than can be used, while at another time the power demand will exceed the plant generating capacity. Operating records are available to bear witness to the fact that these irregularities between power production and power demand can economically be smoothed out by interchange interconnection with an operating electrical utility. On the basis that boilers and turbines are already in operation and that their fixed costs and heat losses are already being absorbed by the industrial, the additional cost to the industrial for an increment of load added to the already existing plant load will be in the neighborhood of 0.4 mill per kw.-hr. for the average modern 15,000-kw. turbine-generator unit.

---

*Specially written for ELECTRICAL ENGINEERING; based upon and prepared from a discussion presented by the author at the joint A. I. E. E.-A. I. & S. E. E., meeting at Pittsburgh, March 13, 1931. Published by special permission of the Association of Iron & Steel Electrical Engineers, Empire Building, Pittsburgh. All rights reserved.

To the electric utility an interconnection with a large industrial establishment is attractive because of the possibilities in load development. Extending a mere interconnection into a full interchange may have features equally attractive to the utility and to the industrial. The utility, like the industrial, is faced with the necessity of having available more generating capacity than required to meet average load conditions, and thus may have available "surplus" power of its own. However, in view of its different basis of operation including the fact that it must use new fuel for each increment of power output, its actual cost per kw-hr. (delivered at the point of interconnection with the utility) is necessarily higher than the cost of the above mentioned industrial dump power. This is particularly true when transmission, distribution, and apparatus losses are taken into consideration. These features combine often to make it possible for the utility to purchase advantageously dump power from the industrial, even to the extent of reducing the output on its own existing equipment.

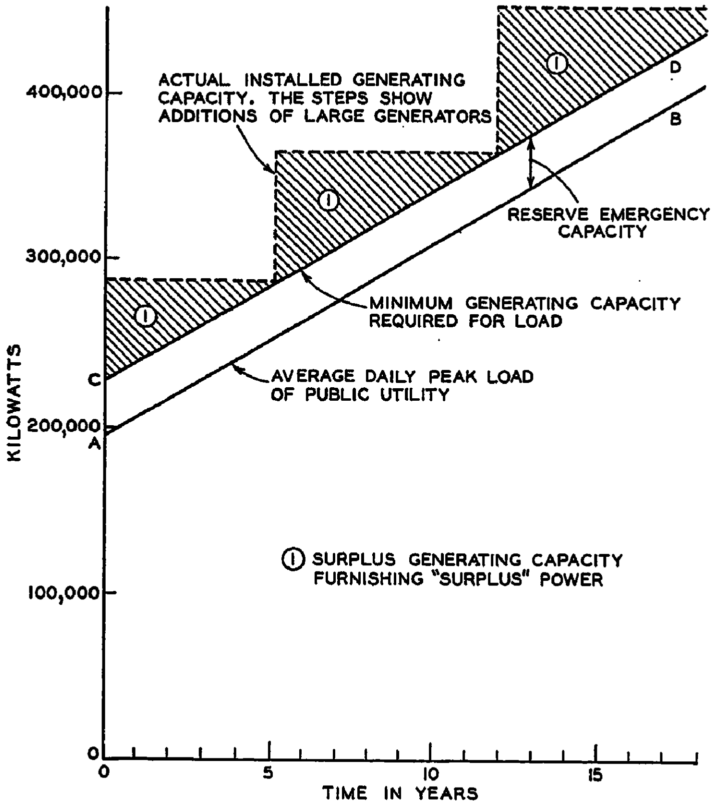


Fig. 1. Diagram indicating common method of caring for load growth in a utility system which must depend solely upon its own plants for increased generating capacity

Another economic angle to the situation, attractive and of importance to both the utility and the industrial, is that through the free interchange of power between the two systems the additions of generating capacity to each system may be "staggered," each making mutually advantageous use of the combined generating capacities of the two systems. This is perhaps one of the most important features involved in the whole interconnection interchange problem and perhaps may be better explained by centering the discussion around the two accompanying illustrations. These illustrations also will help to demonstrate the relative values of the different classes of power previously mentioned as being involved in an interchange interconnection between an industrial establishment and a utility system.

In Fig. 1 the line *A B* represents the constantly-increasing daily peak-load average during the normal growth of a public utility system. When such a system has no major power interchange interconnection, and must care for its own growth with increases in its own generating capacity, a normal margin of safety such as that represented by the vertical distance between the line *A B* and the line *C D* must be maintained. Thus the line *C D* represents the constantly increasing minimum of generating capacity that must be maintained for system operating safety. In the interests of operating efficiency and investment economy, increments in generating capacity must be made in relatively large units, such as those indicated by the projection above the line *C D*.

The capacity shown by the vertical distance between the line *C D* and the dotted lines representing the upper margin of the added capacity blocks represents "surplus generating capacity" held idle and in reserve waiting for system growth. The investment in this surplus capacity must be made *in advance* of the requirements of the system for *any part of its output*, and the fixed charges on this investment must be absorbed by the system as a whole.

When two systems make an interconnection for the purpose of interchanging energy and sharing the beneficial results of such an interchange, the combined operations can best be explained by the aid of Fig. 2, in which the upper section represents the operations of the electric utility and the lower section the operations of the interconnected industrial establishment. The sloping line *C D* represents the minimum safe generating capacity as in Fig. 1. Superimposed on line *C D* are the blocks enclosed by dotted lines representing the normal additions in generating capacity that were shown in Fig. 1. The sloping line *E F* in the lower section represents the same values for the industrial establishment. An hypothetical set of additions to generating capacity on the industrial system are shown in the steps on sloping line *E F*.

A typical normal set of operating conditions that might obtain at the beginning of operation of an interchange agreement may well be assumed to be as shown in Fig. 2. Both companies have power from surplus generating capacity available for sale. Because the electric-utility system does not *need* additional energy the industrial takes advantage of contract clauses permitting the sale of low-priced dump energy, and delivers that kind of energy to the utility system. With the growth of the industrial load its surplus generating capacity gradually is used up and at point 2 the industrial load has grown to a value that requires additional generating capacity; however because of the relatively small capacity required it is more economical to arrange for power purchase from the utility, and by so doing delay an investment in additional generating capacity until a definite load for the reserve unit has been developed.

Because of "minimum clauses" probable in such a power interchange contract, an actual purchase up to the amount of the specified minimum takes place and the industrial buys a small block of power thereby shutting down its most inefficient unit. At point 3 the utility reserve has decreased, as a result of its own load growth, to a point which requires that the industrial again pick up its load. Because of the economy of large units the industrial installs more capacity than is immediately required, and again takes advantage of the low-priced dump-energy clauses to deliver power to the utility system earning at least the fixed charges on its investment in surplus generating capacity, which otherwise would be idle and non-productive between points three and four. At point four the utility has used up its own reserve and is in the market for the purchase of surplus capacity which in this case can now be furnished by the industrial establishment until such time as point five is reached. At that time the utility must have additional generating capacity available for operation, and the first cycle has been completed. These cycles may be repeated indefinitely, the actual span of years per cycle depending upon conditions prevailing.

Fig. 2 indicates that during periods 1-2, 3-4, 5-6, 7-9, and beyond 10, the industrial profits by the sale of dump power and the utility profits by the purchase of that very cheap power. Some power is supplied to the electric utility by the industrial from its own surplus generating capacity during the periods from 4 to 5 and from 9 to 10. During periods 2-3 and 6-7, the industrial has purchased base-load power from the utility. The utility has sold some power from equipment that otherwise would have been idle, and thus has helped to carry the fixed charges on the otherwise idle equipment, and also has been able to delay the large investment in new generating capacity for the periods of time represented by the time increment between point 4 and point 5, and between points 8 and 10. A parallel situation has been comparably remunerative to the industrial establishment. A utility investment in additional generating capacity may easily reach $6,000,000, which if delayed for even one year means a saving of some $780,000 in fixed charges. Large industrial establishments may spend as much as $2,000,000 on power plant equipment; hence the fixed charges on that investment will amount to $260,000 per year, and that investment probably can be delayed for a relatively longer time than the corresponding utility investment. These savings represent some of the fruits of power interchange between the two systems.

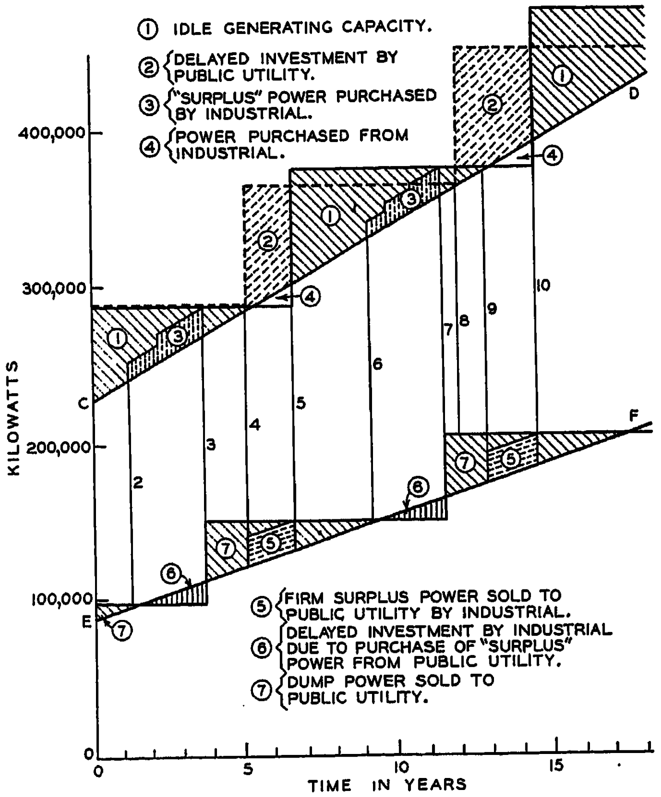

Fig. 2. Diagram showing interlocking development of interconnected utility and industrial systems where mutual use is made of total generating capacity of combined systems

In this brief sketch the attempt has been to outline some of the important advantages to both parties that may result from a free interchange of electric energy between the system of a large industrial establishment and an electric utility system, particularly where the industrial establishment has the characteristics of some of the large steel mills. It is of sufficient importance to warrant its being emphasized again, however, that an interconnection or an interchange contract between a utility and an industrial system must provide for definite profit to both parties if such a contract is to endure.

Asheville, N. C., as it appears from the slopes of nearby Beaucatcher Mountain

Summer Convention Program Announced

Offers Timely Technical Topics Attractively Seasoned With Recreation Features 'Midst Scenic Splendors of the Old South

ASHEVILLE, North Carolina, will be host to the 1931 A. I. E. E. summer convention which will be held June 22-26, with headquarters at the Grove Park Inn. An exceptional program combining the annual business meeting, technical sessions, entertainment, and sports, with ample opportunity to see some of the splendor of the mountains surrounding Asheville, has been arranged by the general convention committee. Excellent concrete highways lead from the city in all directions and wind their way over the various mountain ranges to such points of scenic interest as Chimney Rock, Lake Lure, Mount Pisgah, and the Pisgah National Forest and Game Reserve.

TECHNICAL AND BUSINESS SESSIONS

A selection of specially excellent papers from a wealth of material comprises a technical program of broad scope and current interest. Symposiums comprise three of the sessions; one on the important subject of system interconnections; another on the interesting topic of communication systems for electric utilities; a third dealing with the history of electrical units, the volt, the ampere and the ohm. Four other sessions will present papers describing the latest developments in the fields of power cables, automatic stations, electrical machinery, and research. Annual reports of the Institute's technical committees, reviewing the advances made in theory and practise during the past year, will be available at one of the sessions. A tentative list of the papers for each of these sessions is given in the accompanying tentative program.

The business side of the convention will include the annual meeting of the Institute, a report of the tellers' committee covering election of officers for 1931-1932, the president's address and presentation of prizes for papers. The Lamme Medal, awarded several months ago, will be presented to Dr. William J. Foster, Schenectady, N. Y., "for his contributions to the design of rotating alternating-current machinery."

ENTERTAINMENT AND SPORTS

Asheville long has been noted for its wonderful climate and the natural beauty of the surrounding country. Attractive trips have been arranged each day for the ladies attending the convention, with luncheons at noted resorts; several bridge games will be arranged.

The president's reception, followed by dancing, will be held on the first night of the convention, Monday, June 22, at the Grove Park Inn. An informal get-together dinner followed by dancing will be held at the George Vanderbilt Hotel Tuesday evening, June 23. Attractive entertainment features will be provided at this dinner. The convention banquet will be held at the Grove Park Inn Wednesday evening, June 24, also to be followed by dancing.

Facilities of the Biltmore Forest and the Asheville country clubs will be at the disposal of those attending. The customary golf and tennis tournaments for the Mershon Cups will be held. The golf courses at Biltmore Forest and

Asheville country clubs will be at their best in June and are sure to prove attractive to golfers and near-golfers.

Both of these clubs also afford fine tennis courts.

Notice of A. I. E. E. ANNUAL MEETING

The Annual Meeting of the American Institute of Electrical Engineers will be held in the Grove Park Inn, at Asheville, N. C. at 10 a. m. on Monday, June 22, 1931. This will constitute one session of the annual summer convention, which is to be held in Asheville June 22-26.

At this meeting the annual report of the board of directors, and the report of the committee of tellers concerning the ballots cast for the recent election of officers will be presented.

Such other business, if any, as properly may come before an annual business meeting may be considered.

(Signed) F. L. HUTCHINSON,
National Secretary.

OUTLINE OF PROGRAM

(Eastern Standard Time throughout)

MONDAY, JUNE 22

9:00 a. m.	Registration
10:00 a. m.	Annual business meeting of the Institute Address of welcome by the mayor of Asheville Annual report of the board of directors (in abstract) by F. L. Hutchinson, national secretary Report of tellers committee on election of officers; introduction of and response from president-elect. Presentation of prizes for papers Presidential address, by W. S. Lee Lamme Medal presentation
2:00 p. m.	Conference of officers, delegates, and members Qualifying round for Mershon trophy, at Biltmore Forest Country Club Tennis at Asheville Country Club
2:30 p. m.	Ladies' drive about city followed by tea at Mountain Meadows
9:00 p. m.	President's reception—dancing—at Grove Park Inn

TUESDAY, JUNE 23

9:00 a. m.	Registration
9:30 a. m.	Two technical sessions— (a) Symposium on communication services for electric utilities (b) Electrical machinery
1:00 p. m.	Ladies' luncheon and bridge, at Biltmore Forest Country Club
2:00 p. m.	Conference of officers, delegates, and members (continued) Sports as scheduled
7:00 p. m.	Get-together dinner, at George Vanderbilt Hotel

WEDNESDAY, JUNE 24

9:30 a. m.	Two technical sessions— (c) Symposium on interconnections (d) Symposium on electrical units
12:30 p. m.	Directors' luncheon and meeting, at Grove Park Inn
2:00 p. m.	Trip to Biltmore house and estate Sports as scheduled
7:00 p. m.	Convention banquet, at Grove Park Inn

THURSDAY, JUNE 25

9:30 a. m.	Two technical sessions— (e) Automatic stations (f) Cables Semi-finals in golf and tennis
2:00 p. m.	Technical session— (g) Research, selected subjects, technical committee reports Finals in golf and tennis
2:30 p. m.	Drive to Chimney Rock and Lake Lure for tea

FRIDAY, JUNE 26

All-day excursions, choice of:

(1) Carolina Power and Light Company's Waterville plant

(2) Champion Fibre Company and American Enka Corp.

(3) Mount Pisgah

LADIES PROGRAM

MONDAY, JUNE 22

10:00 a. m.	Opening of convention President's Address, by W. S. Lee
2:30 p. m.	Drive about city followed by tea at Mountain Meadows
9:00 p. m.	President's reception—dancing, at Grove Park Inn

TUESDAY, JUNE 23

1:00 p. m.	Ladies' luncheon and bridge at Biltmore Forest Country Club
7:00 p. m.	Get-together dinner at George Vanderbilt Hotel

Waterville 135,000-kva. hydroelectric plant of the Carolina Power & Light Company

Wednesday, June 24

2:00 p. m. Trip to Biltmore house and estate

7:00 p. m. Convention banquet, at Grove Park Inn

Thursday, June 25

2:30 p. m. Drive to Chimney Rock and Lake Lure for tea

Friday, June 26

All-day excursions, choice of trips as scheduled

Trips

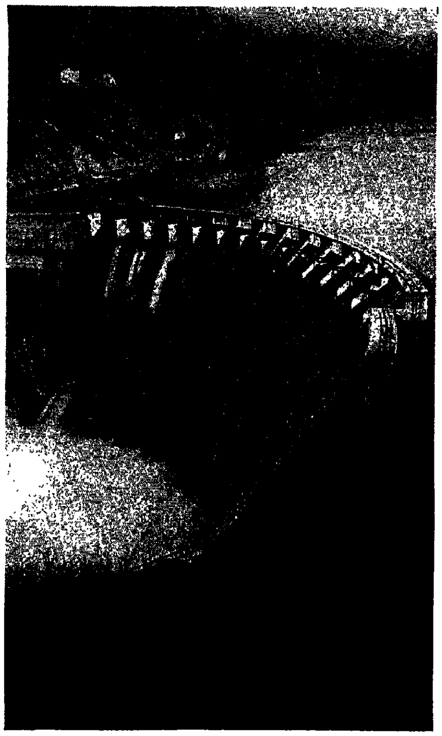
Friday, June 26, will be devoted to an all-day excursion with a choice of one of the following trips: Carolina Power and Light Company, Waterville plant; Champion Fibre Company and American Enka Corp.; Mount Pisgah.

The Waterville plant of the Carolina Power and Light Company is situated on the Big Pigeon River close to the Tennessee state line. Twelve miles upstream a concrete arch dam, 200 ft. high and about 700 ft. long at the top, forms a reservoir from which water is conducted to the plant through a concrete-lined tunnel approximately 33,000 ft. in length. Construction is in two sections known as the upper and lower levels, connected by a vertical circular section known as the gap shaft. The power house contains three 45,000-kva., 13.8-kv., 400-r. p. m. vertical generator units each directly connected to a 55,000-hp. Francis type waterwheel. The unit system is employed and each generator is connected directly to the step-up bank of transformers without low-voltage oil circuit breakers.

Through the Waterville high-voltage bus an interconnection is formed which establishes a complete connection between the Great Lakes and the Gulf of Mexico. Transmission lines interconnect with the Appalachian Electric Power Company to the North, the Tennessee Public Service Company and Tennessee Electric Power Company to the West, and the Duke Power Company to the South, as well as supplying the Carolina Power and Light Company's load in western North Carolina.

The large Canton, N. C., plant of the Champion Fibre Company is unique in the history of industrial development in that it serves the paper industry as well as the tanning industry. When chestnut wood is employed as the raw material to produce soda pulp the tannin must first be extracted. The tannin extract unit for this purpose has a capacity of 500 barrels of liquid tannin extract per day. Sulphate pulp is produced in large quantities from the hemlock and spruce. Another mill produces high-grade book, bond, tablet, and envelope papers and has a daily capacity of 100 tons. Chlorine used for the bleaching of pulp is produced by an electrolytic plant having a capacity of 70 tons daily. The chief by-products of this industry consists of highly volatile methyl compounds, turpentine, and sodium resinate, obtained from the cooking of pine wood for sulphate pulp.

Mount Pisgah, with an altitude of 5,749 ft. is the principal high point in the Pisgah National Forest and Game Preserve. Its summit affords a panorama view of Buncombe, Transylvania, Henderson, and Haywood counties, overlooking Little Bald, Big Bald, Cold Mountain, and Eagles Nest. The beautiful mountain laurel and rhododendron also will be in bloom during June. This excursion consists of approximately a 60-mile round trip. Delightful meals and hotel accommodations may be secured at the famous Pisgah Forest Inn, near the top of the mountain.



Waterville dam of the Carolina Power & Light Company

Railroad Rates

It has been ascertained that in nearly all cases the summer tourist rates are lower than those offered by the convention certificate plan. On this account certificate rates are not being arranged and members are advised to purchase Summer Tourist tickets to Asheville, N. C.

Convention Hotel Rates

Reservations for hotel accommodations should be made by writing directly to the hotel preferred. Rates for rooms with bath are:

Hotel	Plan	Single	Double (per person)	No. of Guests
Grove Park	A	$12	$10	400
George Vanderbilt	E	3	2.50	400
Battery Park	E	3.50	3	400
The Manor	A	9	8	100

All hotels are within ten minutes' easy driving of the convention headquarters hotel.

Committees

The general convention committee for the 1931 summer convention consists of the following members, who are officers or chairmen of other committees as indicated: E. P. Coles, chairman; C. E. Waddell, honorary chairman; W. S. Rodman, vice-president; M. E. Lake, secretary-treasurer; R. R. Laxton, assistant secretary-treasurer; A. E. Knowlton, meetings and papers committee; E. S. Lee, sections committee. The following members are chairmen of subcommittees: T. F. Ball, publicity; Mrs. F. Q. Boyer, ladies; W. S. Lee, Jr., hotels and registration; W. E. Mitchell, finance; F. L. Moser, transportation and trips; J. E. Sirrine, sports; and C. E. Waddell, entertainment.

Tentative Technical Program

Tuesday—9:30 a. m.

(A)—Symposium on Communication Services for Electric Utilities

Communication Services for Electric Utilities, by C. F. Craig, American Telephone & Telegraph Company; R. N. Conwell, Public Service Electric & Gas Company; G. W. Keenan, Pennsylvania-New Jersey Interconnection; and E. C. Briggs.

Communication in the Western Division of the Niagara Hudson System, by Colonel William Kelly, Niagara Hudson Power Corporation.

Communication Facilities of a Metropolitan Power System, by P. B. Juhnke, Commonwealth Edison Company.

Communication Services for the New England Power Association, by C. A. Booker, New England Power Association; and M. E. Clark, New England Telephone and Telegraph Company.

Communication Service of the Arkansas Power and Light Company, by C. E. Stewart, Arkansas Power & Light Company.

Tuesday—9:30 a. m.

(B)—Electrical Machinery

Reestablishing Excitation of a Loaded Alternator in Parallel with Others, by D. D. Higgins and E. Wild, Commonwealth Edison Company.

The Calculation of the Constants of Synchronous Machines, by L. A. Kilgore, Westinghouse Electric & Manufacturing Company.

Determination of Synchronous Machine Constants by Test, by S. H. Wright, Westinghouse Electric & Manufacturing Company

Transient Oscillations in Distributed Windings, by L. V. Bewley, General Electric Company.

Wednesday—9:30 a. m.

(C)—Symposium on Interconnections

Interconnection Services—Their Classification and Evaluation, by A. E. Bauhan, Public Service Electric & Gas Company.

Interconnection—New England District, by E. W. Dillard and W. R. Bell, New England Power Engineering and Service Corporation.

The Pennsylvania–Ohio–West Virginia Interconnection, by H. S. Fitch, West Penn Power Company.

Interconnection Development and Operation, by G. M. Keenan, Pennsylvania-New Jersey Interconnection.

Wednesday—9:30 a. m.

(D)—Symposium on Electrical Units

International Standard of Electromotive Force and Its Low-Temperature Coefficient Form, by Marion Eppley, The Eppley Laboratory, Inc.

Design of Potentiometers, by I. Melville Stein, Leeds and Northrup Company.

Electrical Units and Their Application, by L. T. Robinson, General Electric Company.

History of the Unit of Electrical Resistance with Special Reference to Mercury Standards for the Ohm, by H. B. Brooks, National Bureau of Standards.

Thursday—9:30 a. m.

(E)—Session on Automatic Stations

Supervisory Control Systems, by O. K. Marti, American Brown Boveri Company.

Supervisory Control for A-C. Electrified Railroads, by C. P. West, Westinghouse Electric & Manufacturing Company; and H. C. Griffith, Pennsylvania Railroad Company.

Automatic Combustion Control, by C. H. Sanderson and E. B. Ricketts, New York Edison Company.

Operating Experience with Automatic Stations, by F. F. Ambuhl, Toronto Hydro-Electric System; and Garland Stamper, Columbia Engineering & Management Corporation.

Three Years' Operating Experience with Miniature Switchboard Supervisory Automatic Control, by R. M. Stanley, Byllesby Engineering & Management Corporation.

Thursday—9:30 a. m.

(F)—Cables

Economics of High-Voltage Cable, by D. W. Roper, Commonwealth Edison Company.

Characteristics of Oil-Filled Cable, by G. B. Shanklin and F. H. Buller, General Electric Company.

A Complete Oil-Filled Cable System—Condenser Joints and Terminals, by R. W. Atkinson and D. M. Simmons, General Cable Corporation.

Insulation Variability—Its Influence in Determining Breakdown Voltages, by D. C. Holmes, West Virginia University.

Thursday—2:00 p. m.

(G)—Research and Selected Subjects Technical Committee Reports

Extinction of Short A-C. Arcs, by T. E. Browne, Jr., Westinghouse Electric & Manufacturing Company.

A Corona-Tube Voltage Regulator, by H. W. Dodge and C. H. Willis, Princeton University.

Residual Air and Moisture on Impregnated-Paper Insulation—III, by J. B. Whitehead and F. Hamburger, Jr., Johns Hopkins University.

The Application of the Cooperative Method of Instruction to Engineering Schools and Polytechnic Institutes, by D. C. Jackson, Jr., University of Kansas.

Arcing Faults on Transmission Systems, by J. R. Eaton, Consumers Power Company; J. K. Peck, N. E. L. A.; and J. M. Dunham, American Telephone & Telegraph Company.

C. E. Grunsky to Speak at Pacific Coast Convention

C. E. Grunsky of San Francisco, internationally known to engineering circles, and popular and well-beloved as president (second term) of the American Engineering Council, will be the feature speaker and an honor guest of the forthcoming Pacific Coast convention. Thus Mr. Grunsky will lend his rare talent to the already indisputable attractiveness of the convention's technical program, while adding the charm of his own personality to the attractive natural beauties of the Lake Tahoe region, so sure of appeal to the "tired engineer" and his family attending the Pacific Coast's "vacation convention."

August 25-28, 1931, are the dates set for the convention, carefully chosen to fit as nearly as possible the opening dates of fall school terms and to permit college students to attend without missing classes, and families to fit the convention into vacation plans without interference with the children's school activities.

D. I. Cone, chairman of the convention technical program committee, has announced that there will be four technical sessions, two student sessions, and one evening session, promising a particularly well-balanced, interesting and timely technical program. A. G. Jones, chairman of the convention entertainment committee, has reported that the proposed entertainment features include a barbecue supper, steamer rides around Lake Tahoe, several special features designed exclusively for the ladies, and participation in a colorful street show and dance put on by the resort village.

A. S. T. M. to Exhibit Testing Apparatus and Machines

For the first time in history, the American Society for Testing Materials will sponsor an exhibit of testing apparatus and machines in conjunction with its annual meeting to be held at The Stevens Hotel, Chicago, June 22-26. This exhibit, in which government, institutional, and private laboratories are expected to participate, will display equipment used in the testing of materials and products including recording, control, metallographic, optical, chemical, pyrometric and physical devices, fatigue machines, distributors, etc., exhibited by the leading companies in these fields, as well as by foreign companies covering practically every phase of the testing field. Another unique feature of the exhibit will be participation by certain of the society's committees; they have signified their intention of showing apparatus developed for special committee work, not yet commercially produced, but developed for specific tests and determinations.

A. A. A. S. and Associates Plan Week of Meetings

Launching the plan of holding annually a summer meeting of truly national character, the American Association for the Advancement of Science, together with associated societies, is planning a series of meetings, the first of which will be held in Pasadena, June 15-20 inclusive; the 1932 meeting will be in New Haven, Connecticut; the 1933 meeting in Chicago; and the 1934 meeting back to the Pacific Coast in San Francisco.

At these meetings, each group extending over the period of a full week, scientific sessions will be confined chiefly to the mornings, with the emphasis of the session on symposia; afternoons to be given over to discussion, personal contacts and excursions. Both Professor Thomas H. Morgan, (Calif. Inst. Tech.) retiring president, and Professor Franz Boas, (Columbia, Miss.) recently elected president of the association, are planning to attend the 1931 meetings.

Special round trip rates will be offered by the railroads, making the traveling expense from New York and return approximately $140.00; from Chicago, $90.00. A preliminary program giving the plans in greater detail will become available by mail as soon as sufficient information can be assembled from sections and affiliates.

Summary of Some Pittsburgh Discussions

ONLY discussion given at the meeting and submitted in writing in accordance with A. I. E. E. rules governing it is summarized; complete discussion, together with all papers so approved, will be published in the TRANSACTIONS. The titles of the papers and the names of their respective authors were published on page 140 of the Feb., 1931, issue of ELECTRICAL ENGINEERING.

Alternating-Current Low-Voltage Networks

Six papers were presented dealing with two phases of the network problem. Three of these gave attention to what might be termed the theoretical or fundamental side of the question, while the others described new installations either recently completed or under way.

Cable Burn-Off Characteristics
